from the system and spray a small amount on the foam end until the solution starts to drip. Then, use the
soaked foam swab to wipe the connectors on the boards. Presoaked wipes are the easiest to use—simply
wipe them along the contacts to remove any accumulated dirt and leave a protective coating behind.
On the motherboard, pay special attention to the slot connectors. Be liberal with the liquid; resoak the foam swab repeatedly, and vigorously clean the connectors. Don’t worry if some of the liquid drips on the surface of the motherboard. These solutions are entirely safe for the whole board and will not damage the components.

Use the solution to wash the dirt off the gold contacts in the slot connectors, and then clean any other connectors on the board. Clean the keyboard and mouse connectors, the grounding positions where screws ground the board to the system chassis, the power-supply connectors, the speaker connectors, and the battery connectors.

If you are cleaning a plug-in board, pay special attention to the edge connector that mates with the slot connector on the motherboard. When people handle plug-in cards, they often touch the gold contacts on these connectors. Touching the gold contacts coats them with oils and debris, which prevents proper contact with the slot connector when the board is installed. Make sure these gold contacts are free of all finger oils and residue. It is a good idea to use one of the contact cleaners that has a conductive lubricant, which makes it easier to push the adapter into the slot and also protects the contacts from corrosion.

You also should use the swab and solution to clean the ends of ribbon cables or other types of cables or connectors in a system. Clean the floppy drive cables and connectors, the hard disk cables and connectors, and any others you find. Don’t forget to clean the edge connectors that are on the disk drive logic boards, as well as the power connectors to the drives.

Cleaning the Keyboard and Mouse

Keyboards and mice are notorious for picking up dirt and garbage. If you ever open up an older keyboard, you will be amazed at the junk you find in there.

To prevent problems, you should periodically clean the keyboard with a vacuum cleaner. An alternative method is to turn the keyboard upside down and shoot it with a can of compressed air. This blows out the dirt and debris that has accumulated inside the keyboard and possibly prevents future problems with sticking keys or dirty keyswitches.

If a particular key is stuck or making intermittent contact, you can soak or spray that switch with contact cleaner. The best way to do this is to first remove the keycap and then spray the cleaner into the switch. This usually does not require complete disassembly of the keyboard. Periodic vacuuming or compressed gas cleaning prevents more serious problems with sticking keys and keyswitches.

Most mice are easy to clean. In most cases, a twist-off locking retainer keeps the mouse ball retained in the body of the mouse. By removing the retainer, the ball drops out. After removing the ball, you should clean it with one of the electronic cleaners. I recommend a pure cleaner instead of a contact cleaner with lubricant because you do not want any lubricant on the mouse ball. Then, wipe off the rollers in the body of the mouse with the cleaner and some swabs.

Monthly cleaning of a mouse in this manner eliminates or prevents skipping or erratic movement. I also recommend a mouse pad for most ball-type mice because the pad prevents the mouse ball from picking up debris from your desk.

Other pointing devices requiring little or no maintenance are the IBM-designed TrackPoint and similar systems introduced by other manufacturers, such as the Glidepoint by Alps. These devices are totally sealed and use pressure transducers to control pointer movement. Optical mice that don’t use a ball or roller mechanism also require little or no maintenance. Because they are sealed, cleaning need only be performed externally and is as simple as wiping off the device with a mild cleaning solution to remove oils and other deposits that have accumulated from handling them.
**Hard Disk Maintenance**

Certain preventive maintenance procedures protect your data and ensure that your hard disk works efficiently. Some of these procedures actually minimize wear and tear on your drive, which prolongs its life. Additionally, a high level of data protection can be implemented by performing some simple commands periodically. These commands provide methods for backing up (and possibly later restoring) critical areas of the hard disk that, if damaged, would disable access to all your files.

**Defragmenting Files**

Over time, as you delete and save files to a hard disk, the files become fragmented. This means they are split into many noncontiguous areas on the disk. One of the best ways to protect both your hard disk and the data on it is to periodically defragment the files on the disk. This serves two purposes. One is that by ensuring that all the files are stored in contiguous sectors on the disk, head movement and drive wear and tear is minimized. This has the added benefit of improving the speed at which the drive retrieves files by reducing the head thrashing that occurs every time it accesses a fragmented file.

The second major benefit, and in my estimation the more important of the two, is that in the case of a disaster in which the FATs and root directory are severely damaged, the data on the drive can usually be recovered easily if the files are contiguous. On the other hand, if the files are split up in many pieces across the drive, figuring out which pieces belong to which files is virtually impossible without an intact FAT and directory system. For the purposes of data integrity and protection, I recommend defragmenting your hard disk drives on a monthly basis.

The three main functions in most defragmentation programs are as follows:

- File defragmentation
- File packing (free space consolidation)
- File sorting

Defragmentation is the basic function, but most other programs also add file packing. Packing the files is optional on some programs because it usually takes additional time to perform. This function packs the files at the beginning of the disk so all free space is consolidated at the end of the disk. This feature minimizes future file fragmentation by eliminating any empty holes on the disk. Because all free space is consolidated into one large area, any new files written to the disk are capable of being written in a contiguous manner with no fragmentation.

The last function, file sorting (sometimes called disk optimizing), is not usually necessary and is performed as an option by many defragmenting programs. This function adds a tremendous amount of time to the operation and has little or no effect on the speed at which information is accessed. It can be somewhat beneficial for disaster recovery purposes because you will have an idea of which files came before or after other files if a disaster occurs. Not all defragmenting programs offer file sorting, and the extra time it takes is probably not worth any benefits you will receive. Other programs can sort the order that files are listed in directories, which is a quick and easy operation compared to sorting the file ordering the disk.

Windows 9x/Me/2000/XP include a disk defragmentation program with the operating system, which you can use on any file system the OS supports. For older DOS, Windows 3.x, and some versions of NT, you must purchase a third-party defragmentation program. Norton Utilities includes a disk defragmenter, as do many other utility packages. If you elect to use a third-party product on a Windows 9x/Me/2000/XP system, be certain that it supports the file system you use on your drives. Running a FAT16 defragmentation program on a FAT32 drive can cause severe problems. An excellent third-party defrag program that works on all systems is VOPT by Golden Bow. See the Vendor List on the DVD for more information on these programs.
Before you defragment your disks, you should run a disk repair program, such as ScanDisk or Norton Disk Doctor, even if you are not experiencing any problems. This ensures that your drives are in good working order before you begin the defragmentation process.

**Windows Maintenance Wizard**

Windows 98 and above include a Task Scheduler program that enables you to schedule programs for automatic execution at specified times. The Maintenance Wizard walks you through the steps of scheduling regular disk defragmentations, disk error scans, and deletions of unnecessary files. You can schedule these processes to execute during non-working hours, so regular system activities are not disturbed.

**Virus Checking**

Viruses are a danger to any system, and making scans with an antivirus program a regular part of your preventive maintenance program is a good idea. Many aftermarket utility packages are available that scan for and remove viruses. No matter which of these programs you use, you should perform a scan for virus programs periodically, especially before making hard disk backups. This helps ensure that you catch any potential virus problem before it spreads and becomes a major catastrophe. In addition, selecting an antivirus product from a vendor that provides regular updates to the program’s virus signatures is important. The signatures determine which viruses the software can detect and cure, and because new viruses are constantly being introduced, these updates are essential.

**Tip**

Because viruses are more dangerous and numerous than ever, be sure to enable the automatic update feature found in most recent antivirus programs to keep your protection up-to-date. Even with a dial-up connection, it takes only a few minutes a day to get downloads. If you have a broadband connection, the latest protection is downloaded in just a few moments.

**Passive Preventive Maintenance Procedures**

Passive preventive maintenance involves taking care of the system by providing the best possible environment—both physical and electrical—for the system. Physical concerns are conditions such as ambient temperature, thermal stress from power cycling, dust and smoke contamination, and disturbances such as shock and vibration. Electrical concerns are items such as ESD, power-line noise, and radio-frequency interference. Each of these environmental concerns is discussed in the following sections.

**Examining the Operating Environment**

Oddly enough, one of the most overlooked aspects of microcomputer preventive maintenance is protecting the hardware—and the sizable financial investment it represents—from environmental abuse. Computers are relatively forgiving, and they are generally safe in an environment that is comfortable for people. Computers, however, are often treated with no more respect than desktop calculators. The result of this type of abuse is many system failures.

Before you set up a new PC, prepare a proper location for it that is free of airborne contaminants such as smoke or other pollution. Do not place your system in front of a window; the computer should not be exposed to direct sunlight or temperature variations. The environmental temperature should be as constant as possible. Power should be provided through properly grounded outlets and should be stable and free from electrical noise and interference. Keep your system away from radio transmitters or other sources of radio frequency energy.

**Note**

I also don’t recommend using computer desks that place the system unit in a sealed cabinet; this is a good way to promote overheating.
Heating and Cooling

Thermal expansion and contraction from ambient temperature changes place stress on a computer system. Therefore, keeping the temperature in your office or room relatively constant is important to the successful operation of your computer system.

Temperature variations can lead to serious problems. You might encounter excessive chip creep, for example. If extreme variations occur over a short period, signal traces on circuit boards can crack and separate, solder joints can break, and contacts in the system can undergo accelerated corrosion. Solid-state components such as chips can be damaged also, and a host of other problems can develop.

Temperature variations can wreak havoc with hard disk drives, too. On some drives, writing to a disk at different ambient temperatures can cause data to be written at different locations relative to the track centers. This can cause read and write problems at a later time.

To ensure that your system operates in the correct ambient temperature, you must first determine your system's specified functional range. Most manufacturers provide data about the correct operating temperature range for their systems. Two temperature specifications might be available, one indicating allowable temperatures during operation and another indicating allowable temperatures under non-operating conditions. IBM, for example, indicates the following temperature ranges as acceptable for most of its systems:

System on: 60–90° Fahrenheit
System off: 50–110° Fahrenheit

For the safety of the disk and the data it contains, avoid rapid changes in ambient temperatures. If rapid temperature changes occur—for example, when a new drive is shipped to a location during the winter and then brought indoors—let the drive acclimate to room temperature before turning it on. In extreme cases, condensation can form on the platters inside the drive head-disk assembly (HDA), which is disastrous for the drive if you turn it on before the condensation has a chance to evaporate. Most drive manufacturers specify a timetable to use as a guide in acclimating a drive to room temperature before operating it. You usually must wait several hours to a day before a drive is ready to use after it has been shipped or stored in a cold environment. Manufacturers normally advise that you leave the drive in its packing until it is acclimated. Removing the drive from a shipping carton when extremely cold increases the likelihood of condensation forming as the drive warms up.

Most office environments provide a stable temperature in which to operate a computer system, but some do not. Be sure to give some consideration to the placement of your equipment.

Power Cycling (On/Off)

As you have just learned, the temperature variations a system encounters greatly stress the system's physical components. The largest temperature variations a system encounters, however, are those that occur during the warm-up period right after you turn on the computer. Powering on a cold system subjects it to the greatest possible internal temperature variations. If you want a system to have the longest and most trouble-free life possible, you should limit the temperature variations in its environment. You can limit the extreme temperature cycling in two simple ways during a cold startup: Leave the system off all the time or leave it on all the time. Of these two possibilities, of course, you probably will want to choose the latter option. Leaving the power on is the best way I know to promote system reliability. If your only concern is system longevity, the simple recommendation is to keep the system unit powered on (or off!) continuously. In the real world, however, there are more variables to consider, such as the cost of electricity, the potential fire hazard of unattended running equipment, and other concerns, as well.

If you think about the way light bulbs typically fail, you can begin to understand how thermal cycling can be dangerous. Light bulbs burn out most often when you first turn them on because the filament must endure incredible thermal stress as it changes temperature, in less than one second,
from ambient to several thousands of degrees. A bulb that remains on continuously lasts longer than one that is turned on and off repeatedly.

The place where problems are most likely to occur immediately at power-on is in the power supply. The startup current draw for the system during the first few seconds of operation is very high compared to the normal operating-current draw. Because the current must come from the power supply, the supply has an extremely demanding load to carry for the first few seconds of operation, especially if several disk drives must be started. Motors have an extremely high power-on current draw. This demand often overloads a marginal circuit or component in the supply and causes it to burn or break with a “snap.” I have seen several power supplies die the instant a system was powered up. To enable your equipment to have the longest possible life, try to keep the temperature of solid-state components relatively constant, and limit the number of startups on the power supply. The only way I know to do this is to leave the system on.

Although it sounds like I am telling you to leave all your computer equipment on 24 hours a day, 7 days a week, I no longer recommend this type of operation. A couple of concerns have tempered my urge to leave everything running continuously. One is that an unattended system that is powered on represents a fire hazard. I have seen monitors catch fire after internally shorting and systems whose cooling fans have frozen, causing the power supply and the entire system to overheat. I do not leave any system running in an unattended building. Another problem is wasted electrical power. Many companies have adopted austerity programs that involve turning off lights and other items when not in use. The power consumption of some of today’s high-powered systems and accessories is not trivial. Also, an unattended operating system is more of a security risk than one that is powered off and locked.

Realities—such as the fire hazard of unattended systems running during night or weekend hours, security problems, and power-consumption issues—might prevent you from leaving your system on all the time. Therefore, you must compromise. Power on the system only one time daily. Don’t power the system on and off several times every day. This good advice is often ignored, especially when several users share systems. Each user powers on the system to perform work on the PC and then powers off the system. These systems tend to have many more problems with component failures.

If you are in a building with a programmable thermostat, you have another reason to be concerned about temperatures and disk drives. Some buildings have thermostats programmed to turn off the heat overnight or over the weekend. These thermostats are programmed also to quickly raise the temperature just before business hours every day. In Chicago, for example, outside temperatures in the winter can dip to –20° (excluding the windchill factor). An office building’s interior temperature can drop to as low as 50° during the weekend. When you arrive Monday morning, the heat has been on for only an hour or so, but the hard disk platters might not yet have reached even 60° when you turn on the system. During the first 20 minutes of operation, the disk platters rapidly rise in temperature to 120° or more. If you still have an inexpensive stepper motor hard disk and begin writing to the disk at these low temperatures, you are setting yourself up for trouble.

**Tip**

If you do not leave a system on continuously, at least give it 15 minutes or more to warm up after a cold start before writing to the hard disk. This practice does wonders for the reliability of the data on your disk.

If you do leave your system on for long periods of time, make sure the screen is blank or displays a random image if the system is not in use. The phosphor on the picture tube can burn if a stationary image is left onscreen continuously. Higher-persistence phosphor monochrome screens are most susceptible, and the color displays with low-persistence phosphors are the least susceptible. Most of the monitors used with today’s PCs will not show the effect of a screen burn. If you ever have seen a monochrome display with the image of some program permanently burned in—even with the display off—you know what I mean. Look at the monitors that display flight information at the airport; they usually show some of the effects of phosphor burn.
Most modern displays that have power-saving features can automatically enter a standby mode on command by the system. If your system has these power-saving functions, enable them because they help reduce energy costs and preserve the monitor.

**Static Electricity**

Static electricity or electro-static discharge (ESD) can cause numerous problems within a system. The problems usually appear during the winter months when humidity is low or in extremely dry climates where the humidity is low year-round. In these cases, you might need to take special precautions to ensure that your PC is not damaged. See Chapter 21, “Power Supply and Chassis/Case,” and Chapter 22 for more information on ESD.

Static discharges outside a system-unit chassis are rarely a source of permanent problems within the system. Usually, the worst possible effect of a static discharge to the case, keyboard, or even a location near the computer is a parity check (memory) error or a system lockup. In some cases, I have been able to cause parity checks or system lockups by simply walking past a PC. Most static-sensitivity problems are caused by improper grounding of the system power. Be sure you always use a three-prong, grounded power cord plugged in to a properly grounded outlet. If you are unsure about the outlet, you can buy an outlet tester, such as those described earlier in this chapter, at most electronics supply or hardware stores for only a few dollars.

Whenever you open a system unit or handle circuits removed from the system, you must be much more careful with static. You can permanently damage a component with a static discharge if the charge is not routed to a ground. I usually recommend handling boards and adapters first by a grounding point such as the bracket to minimize the potential for static damage.

An easy way to prevent static problems is with good power-line grounding, which is extremely important for computer equipment. A poorly designed power-line grounding system is one of the primary causes of poor computer design. The best way to prevent static damage is to prevent the static charge from getting into the computer in the first place. The chassis ground in a properly designed system serves as a static guard for the computer and redirects the static charge safely to the ground. For this ground to be complete, therefore, the system must be plugged in to a properly grounded three-wire outlet.

If the static problem is extreme, you can resort to other measures. One is to use a grounded static mat underneath the computer. Touch the mat first before you touch the computer to ensure that any static charges are routed to ground and away from the system unit's internal parts. If problems still persist, you might want to check out the building's electrical ground. I have seen installations that had three-wire outlets that were rendered useless by the building's ungrounded electrical service.

**Power-Line Noise**

To run properly, a computer system requires a steady supply of clean, noise-free power. In some installations, however, the power line serving the computer also serves heavy equipment, and the voltage variations resulting from the on/off cycling of this equipment can cause problems for the computer. Certain types of equipment on the same power line also can cause voltage spikes—short, transient signals of sometimes 1,000V or more—that can physically damage a computer. Although these spikes are rare, they can be crippling. Even a dedicated electrical circuit used by only a single computer can experience spikes and transients, depending on the quality of the power supplied to the building or circuit.

During the site-preparation phase of a system installation, you should be aware of these factors to ensure a steady supply of clean power:

- If possible, the computer system should be on its own circuit with its own circuit breaker. This setup does not guarantee freedom from interference, but it helps.
- The circuit should be checked for a good, low-resistance ground, proper line voltage, freedom from interference, and freedom from brownouts (voltage dips).
A three-wire circuit is a must, but some people substitute grounding-plug adapters to adapt a grounded plug to a two-wire socket. This setup is not recommended; the ground is there for a reason.

Power-line noise problems increase with the resistance of the circuit, which is a function of wire size and length. So, to decrease resistance, avoid extension cords unless absolutely necessary, and then use only heavy-duty extension cords.

Inevitably, you will want to plug in other equipment later. Plan ahead to avoid the temptation to connect too many items to a single outlet. If possible, provide a separate power circuit for non-computer-related devices.

Air conditioners, coffee makers, copy machines, laser printers, space heaters, vacuum cleaners, and power tools are some of the worst corrupters of a PC system’s power. Any of these items can draw an excessive amount of current and wreak havoc with a PC system on the same electrical circuit. I’ve seen offices in which all the computers begin to crash at about 9:05 a.m. daily, which is when all the coffee makers are turned on!

Also, try to ensure that copy machines and laser printers do not share a circuit with other computer equipment. These devices draw a large amount of power.

Another major problem in some companies is partitioned offices. Many of these partitions are prewired with their own electrical outlets and are plugged in to one another in a sort of power-line daisy-chain, similar to chaining power strips together. I pity the person in the cubicle at the end of the electrical daisy-chain, who is likely to have very erratic power!

As a real-world example of too many devices sharing a single circuit, I can describe several instances in which a personal computer had a repeating parity check problem. All efforts to repair the system had been unsuccessful. The reported error locations from the parity-check message were inconsistent, which normally indicates a problem with power. The problem could have been the power supply in the system unit or the external power supplied from the wall outlet. This problem was solved one day as I stood watching the system. The parity check message was displayed at the same instant that someone two cubicles away turned on a copy machine. Placing the computers on a separate line solved the problem.

By following the guidelines in this section, you can create the proper power environment for your systems and help ensure trouble-free operation.

Radio-Frequency Interference

Radio-frequency interference (RFI) is easily overlooked as a problem factor. The interference is caused by any source of radio transmissions near a computer system. Living next door to a 50,000-watt commercial radio station is one sure way to get RFI problems, but less-powerful transmitters can cause problems, too. I know of many instances in which cordless telephones have caused sporadic random keystrokes to appear, as though an invisible entity were typing on the keyboard. I also have seen RFI cause a system to lock up. Solutions to RFI problems are more difficult to state because every case must be handled differently. Sometimes, simply moving the system eliminates the problem because radio signals can be directional in nature. At other times, you must invest in specially shielded cables for external devices, such as the keyboard and the monitor.

One type of solution to an RFI noise problem with cables is to pass the cable through a toroidal iron core, a doughnut-shaped piece of iron placed around a cable to suppress both the reception and transmission of electromagnetic interference (EMI). Many monitors include a toroid (sometimes spelled torroid) on the cable that connects to the computer. If you can isolate an RFI noise problem in a particular cable, you often can solve the problem by passing the cable through a toroidal core. Because the cable must pass through the center hole of the core, it often is difficult, if not impossible, to add a toroid to a cable that already has end connectors installed.
Radio Shack sells a special snap-together toroid designed specifically to be added to cables already in use. This toroid looks like a thick-walled tube that has been sliced in half. You simply lay the cable in the center of one of the halves, and snap the other half over the first. This type of construction makes adding the noise-suppression features of a toroid to virtually any existing cable easy.

The best, if not the easiest, way to eliminate an RFI problem is to correct it at the source. It is unlikely that you'll be able to convince the commercial radio station near your office to shut down, but if you are dealing with a small radio transmitter that is generating RFI, sometimes you can add a filter to the transmitter that suppresses spurious emissions. Unfortunately, problems sometimes persist until the transmitter is either switched off or moved some distance away from the affected computer.

**Dust and Pollutants**

Dirt, smoke, dust, and other pollutants are bad for your system. The power-supply fan carries airborne particles through your system, and they collect inside. If your system is used in an extremely harsh environment, you might want to investigate some of the industrial systems on the market designed for harsh conditions.

Many companies make special hardened versions of their systems for harsh environments. Industrial systems usually use a different cooling system from the one used in regular PCs. A large cooling fan is used to pressurize the case rather than depressurize it. The air pumped into the case passes through a filter unit that must be cleaned and changed periodically. The system is pressurized so that no contaminated air can flow into it; air flows only outward. The only way air can enter is through the fan and filter system.

These systems also might have special keyboards impervious to liquids and dirt. Some flat-membrane keyboards are difficult to type on, but are extremely rugged; others resemble the standard types of keyboards but have a thin, plastic membrane that covers all the keys. You can add this membrane to normal types of keyboards to seal them from the environment.

A relatively new breed of humidifier can cause problems with computer equipment. This type of humidifier uses ultrasonics to generate a mist of water sprayed into the air. The extra humidity helps cure problems with static electricity resulting from a dry climate, but the airborne water contaminants can cause many problems. If you use one of these systems, you might notice a white, ash-like deposit forming on components. The deposit is the result of abrasive and corrosive minerals suspended in the vaporized water. If these deposits collect on the system components, they can cause all kinds of problems. The only safe way to run one of these ultrasonic humidifiers is to use distilled water. If you use a humidifier, be sure it does not generate these deposits.

If you do your best to keep the environment for your computer equipment clean, your system will run better and last longer. Also, you will not have to open up your unit as often for complete preventive maintenance cleaning.

**Troubleshooting Tips and Techniques**

This section lists basic and general system troubleshooting procedures and guidelines. For specific procedures for troubleshooting a component in the system, use Appendix C, “Troubleshooting Index,” as a quick reference for finding the chapter or section dedicated to that part of the PC.

**Basic Troubleshooting Guidelines**

Troubleshooting PC hardware problems can seem daunting to the uninitiated, but in reality it is much simpler than it seems. Most problems can be diagnosed and corrected using few, if any, special tools and can be accomplished by anybody who can apply simple deductive reasoning and logical thinking. PCs have become more complicated and yet simpler all at the same time. More and more complex internal circuits mean that there are potentially more things that can go wrong—more ways the system can fail. On the other hand, today’s complex circuits are embedded into fewer boards,
with fewer chips on each board and more serial interconnections using fewer pins (fewer wires). The internal consolidation means that isolating which replaceable component has failed is in many ways simpler than ever before. An understanding of the basics of how PCs work, combined with some very simple tools, some basic troubleshooting tips, and logical thinking and common sense, will enable you to effectively diagnose and repair your own systems, saving a tremendous amount of money over taking it to a shop. In some cases, you can save enough money to practically pay for an entire new system. The bottom line with troubleshooting PC problems is that a solution exists for every problem, and through simple practices combined with deductive reasoning, that solution can easily be found.

Modern PCs—More Complicated and More Reliable

Consider this: The modern PC is an incredible collection of hardware and software. Focusing specifically on the hardware, between 50 and more than 400 million transistors exist in modern processors (see the following note). In addition, nearly 4.3 billion transistors are in 512MB of RAM; hundreds of millions of transistors exist in the motherboard chipset, video processor, and video RAM; and millions more are in the other adapter cards or logic boards in the system. Each of these billions of interconnected transistors must not only function properly, but also operate in a strictly enforced timing window, some of which are measured in picoseconds (trillionths of a second). When you realize that your PC will lock up or crash if any one of these transistors fails to operate properly and on time—and/or any one of the billions of circuit paths and interconnections between the transistors or devices containing them fails in any way—it is a wonder that PCs work at all!

Note

There are 77 million transistors in the Pentium M (code named Banias), 55 million transistors in the Pentium 4 (code named Northwood), and more than 54 million in the latest Athlon XP (code named Barton). In the high-end server/workstation processor market, the 100-million-transistor mark was breached by a single-die CPU on May 22, 2000, when Intel introduced a 700MHz version of the Pentium III Xeon (code named Cascades) with 2MB of on-die L2 cache and 1.40 million transistors. This chip was built using older 0.18-micron technology and has an enormous die size of 385 sq:mm. That's more than 19.6mm on each side, or nearly three times the size of the current Pentium 4 die of 131 sq:mm.

The 1GHz Itanium 2 (code named McKinley) processor was introduced on July 8, 2002, and includes 32KB L1, 256KB L2, and up to 3MB of L3 cache integrated into a die containing a whopping 221 million transistors. This chip also uses older 0.18-micron technology and is the biggest I've ever heard of for a processor at 421 sq mm (more than 20.5mm square), which is more than 3.2 times the size of the current Pentium 4.

Finally, the Madison-based 1.5GHz Itanium 2 with 6MB of integrated L3 cache includes an incredible 410 million transistors on a 374 sq mm (more than 19.3mm square) die using newer 0.13-micron technology. It has established new records for transistor count as well as the amount of on-die cache.

Although these server/workstation processors are extreme, the technology used in them eventually filters down to the desktop and mobile processors. We will likely see the 1-billion-transistor mark breached by the follow-ons to these high-end server chips during the next-generation 90-nanometer process lifecycle.

Every time I turn on one of my systems and watch it boot up, I think about the billions upon billions of components and trillions upon trillions of machine/program steps and sequences that have to function properly to get there. As you can now see, many opportunities exist for problems to arise.

Although modern PCs are exponentially more complicated than their predecessors, from another point of view they have become simpler and more reliable. When you consider the complexity of the modern PC, it is not surprising that problems occasionally do arise. However, modern design and manufacturing techniques have made PCs more reliable and easier to service despite their ever-increasing internal complexity. Today's systems have fewer and fewer replaceable components and individual parts, which is a bit of a paradox. The truth is that, as PCs have become more complex, they have also become simpler and easier to service in many ways.
Industry-Standard Replaceable Components

The use of industry-standard components is one of the key features of a PC. This means that virtually all the parts that make up a system are interchangeable with other systems in some manner. This also means that the parts are plentiful, inexpensive, and generally very easy to install. A typical PC typically contains the following replaceable components, most of which are made to industry standards for design and form factor:

- Motherboard
- Processor
- CPU heatsink/fan
- RAM
- CMOS battery
- Chassis with optional fan
- Power supply
- Video card*
- Monitor
- Sound card*
- Spearkers
- Network card*
- Hard drive
- CD-ROM/RW drive
- DVD-ROM/+RW drive
- Floppy drive
- Drive cables
- Keyboard
- Mouse

*May be integrated into the motherboard in some systems.

Although some of the more well-optioned systems might have even more components than listed here, you can see that most PCs have fewer than 20 replaceable “parts.” Some can have as few as 10–15, depending on how many options are present and how they are integrated. From a hardware troubleshooting or repair perspective, one of these components is either improperly installed (configured) or defective. If it’s improperly installed or configured, the component can be repaired by merely reinstalling it or configuring it properly. If it’s truly defective, the component must simply be replaced. When a PC is broken down to the basic replaceable parts, you can see that it really isn’t that complicated, which is why I’ve spent my career helping people to easily perform their own repairs or upgrades and even build entire systems from scratch.

Reinstall or Replace?

When dealing with hardware problems, the first simple truth to understand is that you do not usually repair anything—you reinstall or replace it instead. You reinstall because the majority of PC hardware problems are caused by a particular component being improperly installed or configured. I remember hearing from IBM many years ago that it had found that 60% or more of the problems handled by its service technicians were due to improper installation or configuration, meaning the hardware was not actually defective. This was, in fact, the major impetus behind the plug-and-play revolution, which has eliminated the need to manually configure jumpers and switches on most hardware devices. This has thus minimized the expertise necessary to install hardware properly and has also minimized installation, configuration, and resource conflict problems. Still, plug and play has sometimes been called plug and pray because it does not always work perfectly, sometimes requiring manual intervention to make work properly.

You replace because of the economics of the situation with computer hardware. The bottom line is that it financially is much cheaper to replace a failed circuit board with a new one than to repair it. For example, you can purchase a new, state-of-the-art motherboard for around $100, but repairing an existing board normally costs much more than that. Modern boards use surface-mounted chips that have pin spacings measured in hundredths of an inch, requiring sophisticated and expensive equipment to attach and solder the chip. Even if you could figure out which chip had failed and had the equipment to replace it, the chips themselves are usually sold in quantities of thousands and obsolete chips are usually not available. The net effect of all of this is that the replaceable components in your PC have become disposable technology. Even a component as large and comprehensive as the motherboard is replaced rather than repaired.
Troubleshooting by Replacing Parts

You can troubleshoot a PC in several ways, but in the end it often comes down to simply reinstalling or replacing parts. That is why I normally use a simple “known-good spare” technique that requires very little in the way of special tools or sophisticated diagnostics. In its simplest form, say you have two identical PCs sitting side by side. One of them has a hardware problem; in this example let’s say the memory module (DIMM) is defective. Depending on how and where the defect lies, this could manifest itself in symptoms ranging from a completely dead system to one that boots up normally but crashes when running Windows or software applications. You observe that the system on the left has the problem but the system on the right works perfectly—they are otherwise identical. The simplest technique for finding the problem would be to swap parts from one system to another, one at a time, retesting after each swap. At the point when the DIMMs were swapped, upon powering up and testing (in this case testing is nothing more than allowing the system to boot up and run some of the installed applications), the problem has now moved from one system to the other. Knowing that the last item swapped over was the DIMM, you have just identified the source of the problem! This did not require an expensive ($2,000 or more) DIMM test machine or any diagnostics software. Because components such as DIMMs are not economical to repair, replacing the defective DIMM would be the final solution.

Although this is very simplistic, it is often the quickest and easiest way to identify a problem component as opposed to specifically testing each item with diagnostics. Instead of having an identical system standing by to borrow parts from, most technicians have an inventory of what they call “known-good spare” parts. These are parts that have been previously used, are known to be functional, and can be used to replace a suspicious part in a problem machine. However, this is different from new replacement parts because, when you open a box containing a new component, you really can’t be 100% sure that it works. I’ve been in situations in which I’ve had a defective component and replaced it with another (unknown to me) defective new component and the problem remained. Not knowing that the new part I just installed was also defective, I wasted a lot of time checking other parts that were not the problem. This technique is also effective because so few parts are needed to make up a PC and the known-good parts don’t always have to be the same (for example, a lower-end video card can be substituted in a system to verify that the original card had failed).

Troubleshooting by the Bootstrap Approach

Another variation on this theme is the “bootstrap approach,” which is especially good for what seems to be a dead system. In this approach, you take the system apart to strip it down to the bare minimum necessary, functional components and test it to see whether it works. For example, you might strip down a system to the chassis/power supply, bare motherboard, CPU (with heatsink), one bank of RAM, and a video card with display and then power it up to see whether it works. In that stripped configuration, you should see the POST or splash (logo) screen on the display, verifying that the motherboard, CPU, RAM, video card, and display are functional. If a keyboard is connected, you should see the three LEDs (capslock, scrlock, and numlock) flash within a few seconds after powering on. This indicates that the CPU and motherboard are functioning because the POST routines are testing the keyboard. After you get the system to a minimum of components that are functional, you should reinstall or add one part at a time, testing the system each time you make a change to verify it still works and that the part you added or changed is not the cause of a problem. Essentially, you are rebuilding the system from scratch using the existing parts, but doing it one step at a time.

Many times problems are caused by corrosion on contacts or connectors, so the mere act of disassembling and reassembling a PC will “magically” repair it. Over the years, I’ve disassembled, tested, and reassembled many systems only to find no problems after the reassembly. How can merely taking it apart and reassembling repair a problem? Although it might seem that nothing was changed and everything is installed exactly like it was before, in reality simply unplugging and replugging renews
all the slot and cable connections between devices, which is often all the system needs. Some useful troubleshooting tips include

- Eliminate unnecessary variables or components that are not pertinent to the problem.
- Reinstall, reconfigure, or replace only one component at a time.
- Test after each change you make.
- Keep a detailed record (write it down) of each step you take.
- Don’t give up! Every problem has a solution.
- If you hit a roadblock, take a break or work on another problem. A fresh approach the next day often reveals things you overlooked.
- Don’t overlook the simple or obvious. Double- and triple-check the installation and configuration of each component.
- Keep in mind that the power supply is one of the most failure-prone parts in a PC, as well as one of the most overlooked components. A high-output “known-good” spare power supply is highly recommended to use for testing suspect systems.
- Cables and connections are also a major cause of problems, so keep replacements of all types on hand.

Before starting any system troubleshooting, a few basic steps should be performed to ensure a consistent starting point and to enable isolating the failed component:

1. Turn off the system and any peripheral devices. Disconnect all external peripherals from the system, except for the keyboard and video display.
2. Make sure the system is plugged in to a properly grounded power outlet.
3. Make sure the keyboard and video displays are connected to the system. Turn on the video display, and turn up the brightness and contrast controls to at least two-thirds of the maximum. Some displays have onscreen controls that might not be intuitive. Consult the display documentation for more information on how to adjust these settings. If you can’t get any video display but the system seems to be working, try moving the card to a different slot (not possible with AGP adapters) or try a different video card or monitor.
4. To enable the system to boot from a hard disk, make sure no floppy disk is in the floppy drive. Or put a known good bootable floppy with DOS or diagnostics on it in the floppy drive for testing.
5. Turn on the system. Observe the power supply, chassis fans (if any), and lights on either the system front panel or power supply. If the fans don’t spin and the lights don’t light, the power supply or motherboard might be defective.
6. Observe the power on self test (POST). If no errors are detected, the system beeps once and boots up. Errors that display onscreen (nonfatal errors) and that do not lock up the system display a text message that varies according to BIOS type and version. Record any errors that occur and refer to the DVD accompanying this book for a list of BIOS error codes for more information on any specific codes you see. Errors that lock up the system (fatal errors) are indicated by a series of audible beeps. Refer to the DVD for a list of beep error codes.
7. Confirm that the operating system loads successfully.

Note

The Technical Reference section of the DVD accompanying this book contains an exhaustive listing of BIOS error codes, error messages, and beep codes for BIOSs from Phoenix, AMI, Award, Microid Research, and IBM.
Problems During the POST

Problems that occur during the POST are usually caused by incorrect hardware configuration or installation. Actual hardware failure is a far less-frequent cause. If you have a POST error, check the following:

1. Are all cables correctly connected and secured?
2. Are the configuration settings correct in Setup for the devices you have installed? In particular, ensure the processor, memory, and hard drive settings are correct.
3. Are all drivers properly installed?
4. Are switches and jumpers on the baseboard correct, if changed from the default settings?
5. Are all resource settings on add-in boards and peripheral devices set so that no conflicts exist—for example, two add-in boards sharing the same interrupt?
6. Is the power supply set to the proper input voltage (110V–120V or 220V–240V)?
7. Are adapter boards and disk drives installed correctly?
8. Is a keyboard attached?
9. Is a bootable hard disk (properly partitioned and formatted) installed?
10. Does the BIOS support the drive you have installed, and if so, are the parameters entered correctly?
11. Is a bootable floppy disk installed in drive A:?
12. Are all memory SIMMs or DIMMs installed correctly? Try reseating them.
13. Is the operating system properly installed?

Hardware Problems After booting

If problems occur after the system has been running, and without having made any hardware or software changes, a hardware fault possibly has occurred. Here is a list of items to check in that case:

1. Try reinstalling the software that has crashed or refuses to run.
2. Try clearing CMOS RAM and running Setup.
3. Check for loose cables, a marginal power supply, or other random component failures.
4. A transient voltage spike, power outage, or brownout might have occurred. Symptoms of voltage spikes include a flickering video display, unexpected system reboots, and the system not responding to user commands. Reload the software and try again.
5. Try reseating the memory modules (SIMMs, DIMMs, or RIMMs).

Problems Running Software

Problems running application software (especially new software) are usually caused by or related to the software itself, or are due to the fact that the software is incompatible with the system. Here is a list of items to check in that case:

1. Does the system meet the minimum hardware requirements for the software? Check the software documentation to be sure.
2. Check to see that the software is correctly installed. Reinstall if necessary.
3. Check to see that the latest drivers are installed.
4. Scan the system for viruses using the latest antivirus software.
Problems with Adapter Cards
Problems related to add-in boards are usually related to improper board installation or resource (interrupt, DMA, or I/O address) conflicts. Chapter 4, “Motherboards and Buses,” has a detailed discussion of these system resources, what they are, how to configure them, and how to troubleshoot them. Also be sure to check drivers for the latest versions and ensure that the card is compatible with your system and the operating system version you are using.

Sometimes adapter cards can be picky about which slot they are running in. Despite the fact that, technically, a PCI or ISA adapter should be able to run in any of the slots, minor timing or signal variations sometimes occur from slot to slot. I have found on numerous occasions that simply moving a card from one slot to another can make a failing card begin to work properly. Sometimes moving a card works just by the inadvertent cleaning (wiping) of the contacts that takes place when removing and reinstalling the card, but in other cases I can duplicate the problem by inserting the card back into its original slot. When all else fails, try moving the cards around! Because some motherboards share a single IRQ between two PCI slots or between a PCI and an AGP slot, changing one of the PCI cards to another slot can resolve conflicts.

Caution
Note that PCI cards become slot specific after their drivers are installed. By this I mean that if you move the card to another slot, the plug-and-play resource manager sees it as if you have removed one card and installed a new one. You therefore must install the drivers all over again for that card. Don’t move a PCI card to a different slot unless you are prepared with all the drivers at hand to perform the driver installation. ISA cards don’t share this quirk because the system is not aware of which slot an ISA card is in.

Top Troubleshooting Problems
These are some of the most frequently asked troubleshooting questions I receive.

When I power the system on, I see the power LED light and hear the fans spin, but nothing else ever happens.
The fact that the LEDs illuminate and fans spin indicates that the power supply is partially working, but that does not exclude it from being defective. This is a classic “dead” system, which can be caused by almost any defective hardware component. In my experiences I’ve had more problems with power supplies than most other components, so I recommend immediately using a multimeter to measure the outputs at the power supply connectors and ensure they are within the proper 5% tolerances of their rated voltages. Even if the voltage measurements checked out, you should swap in a high-quality, high-power, known-good spare supply and retest. If that doesn’t solve the problem, you should revert to the bootstrap approach I mentioned earlier, which is to strip the system down to just the chassis/power supply, motherboard, CPU (with heatsink), one bank of RAM (one DIMM), and a video card and display. If the motherboard now starts, begin adding the components you removed one at a time, retesting after each change. If the symptoms remain, use a POST card (if you have one) to see whether the board is partially functional and where it stops. Also, try replacing the video card, RAM, CPU, and then finally the motherboard, and verify the CPU and (especially) the heatsink installation.

The system beeps when I turn it on, but there is nothing on the screen.
The beep indicates a failure detected by the ROM POST routines. Look up the beep code in the table corresponding to the ROM version in your motherboard. This can typically be found in the motherboard manual; however, you can also find the beep codes for the most popular AMI, Award, and Phoenix BIOS earlier in this chapter.
I see a **STOP** or **STOP ERROR** in Windows NT/2000/XP.

Many, including corrupted files, viruses, incorrectly configured hardware, and failing hardware, can cause Windows STOP errors. The most valuable resource for handling any error message displayed by Windows is the Microsoft Knowledgebase (MSKB), an online compendium of more than 250,000 articles covering all Microsoft products. You can visit the MSKB at support.microsoft.com, and from there you can use the search tool to retrieve information specific to your problem. For example, say you are receiving Stop 0x0000007B errors in Windows XP. In this case, you should visit the MSKB and enter the error message in the search box. In this case, I typed stop 7B error Windows XP in the box, and it returned two articles, one of which was Microsoft Knowledgebase Article number 324103, titled, “HOW TO: Troubleshoot “Stop 0x0000007B” Errors in Windows XP.” Upon this link, I was taken to the article at support.microsoft.com/default.aspx?scid=kb;en-us;324103, which has a complete description of the problem and solutions. The article states that this error could be caused by the following:

- Boot-sector viruses
- Device driver issues
- Hardware issues
- Other issues

The article explains each issue and solution in detail. All things considered, the MSKB is a valuable resource when dealing with any problems related to or reported by any version of Windows or any other Microsoft software.

I see **Fatal Exception** errors in Windows 95/98/Me.

This is the equivalent of the STOP error in Windows NT/2000/XP. As indicated in the previous answer, this can be caused by both hardware and software problems, and the best place to check for specific solutions is in the Microsoft Knowledgebase (MSKB) at support.microsoft.com.

The system won’t shut down in Windows.

This is another example where the MSKB comes to the rescue. For example, by searching for shutdown problems Windows XP, (substitute the version of Windows you are using), you will quickly find several articles that can help you troubleshoot this type of problem. This problem has been caused by bugs in motherboard ROM (try upgrading your motherboard ROM to the latest version), bugs in the various Windows versions (visit www.windowsupdate.com and install the latest fixes, patches, and service packs), or in some cases configuration or hardware problems. I’ll defer to the MSKB articles for more complete explanations of the Windows issues.

The power button won’t turn off the system.

Desktop PCs built since 1996 mostly use the ATX form factor, which incorporates a special power supply design such that the power switch is connected to the motherboard and not the power supply directly. This enables the motherboard and operating system to control system shutdown, preventing an unexpected loss of power that can cause data loss or file system corruption. However, if the system experiences a problem and becomes frozen or locked up in some way, the motherboard might not respond to the power button, meaning it will not send a shutdown signal to the power supply. It might seem that you will have to pull the plug to power off the system, but fortunately a forced shutdown override is provided. Merely press and hold down the system power button (usually on the front of the chassis) for a minimum of 4 seconds, and the system should power off. The only drawback is that, because this type of shutdown is forced and under the control of the motherboard or operating system, unsaved data can be lost and some file system corruption can result. You should therefore run ScanDisk (found in the Windows Accessories, System Tools folder) in Windows 95/98/Me/NT/2000 or Chkdsk in Windows XP to check and correct any file-system issues after a forced shutdown.
The modem doesn’t work.

First verify that the phone line is good and that you have a dial tone. Then check and, if necessary, replace the phone cable from the modem to the wall outlet. If the modem is integrated into the motherboard, check the BIOS Setup to ensure that the modem is enabled. Try clearing the Enhanced System Configuration Data (ESCD) in the BIOS Setup. This forces the plug-and-play routines to reconfigure the system, which can resolve any conflicts. If the modem is internal and you aren’t using the COM1/COM2 serial ports integrated into the motherboard (as for an external modem), try disabling the serial ports to free up additional system resources. Also, try removing and reinstalling the modem drivers, ensuring that you are using the most recent drivers from the modem manufacturer. If that doesn’t help, try physically removing and reinstalling the modem. If the modem is internal, install it in a different slot. Or, if the modem is external, make sure it has power and is properly connected to the serial or USB port on the PC. Try replacing the external modem power brick and the serial/USB cable. Finally, if you get this far and it still doesn’t work, try replacing the modem and finally the motherboard.

Note that modems are very susceptible to damage from nearby lightning strikes. Consider adding lightning arrestors or surge suppressors on the phone line running to the modem, and unplug the modem during storms. If the modem has failed after a storm, you can be almost certain that it has been damaged by lightning. The strike might have damaged the serial port or motherboard, in addition to the modem. Any items damaged by lightning will most likely need to be replaced.

The keyboard doesn’t work.

The two primary ways to connect a keyboard to a PC are either via the standard keyboard port (usually called a PS/2 port) or via USB. One problem is that many older systems that have USB ports cannot use a USB keyboard because USB support is provided by the operating system—for instance, if the motherboard has a USB port but does not include what is called USB Legacy Support in the BIOS. This support is specifically for USB keyboards (and mice) and was not common in systems until 1998 or later. Many systems that had such support in the BIOS still had problems with the implementation; in other words, they had bugs in the code that prevented the USB keyboard from working properly. If you are having problems with a USB keyboard, check to ensure that USB Legacy Support is enabled in the BIOS. If you are still having problems, make sure you have installed the latest BIOS for your motherboard and any Windows updates from Microsoft. Some older systems never could properly use a USB keyboard, in which case they should change to a PS/2 keyboard instead. Some keyboards feature both USB and PS/2 interfaces, which offer the flexibility to connect to almost any system.

If the keyboard is a PS/2 type and is having problems, the quickest way to verify whether it is the keyboard or the motherboard is to replace the keyboard with a known-good spare. In other words, borrow a working keyboard from another system and try it. If it still doesn’t work, the keyboard controller on the motherboard is most likely defective, meaning the entire board must be replaced. My favorite replacement keyboards come from the PC Keyboard Co. (www.pckeyboard.com), which makes the legendary buckling spring design used by IBM. The company even offers versions with the Trackpoint pointing device built in.

I can’t hear any sound from the speakers.

This can often be as simple as the speakers being unplugged or powered off, so don’t overlook the obvious and check to be sure! Also check the volume controls in Windows or your application to see that they are turned up and not muted. When you are sure the volume is turned up and the speakers have power and are plugged in, you need to verify whether the problem is with the speakers or the sound card. To do this most efficiently, you merely connect different known-good speakers and see whether they work. If they don’t, clearly the issue is in the sound card—possibly the configuration of the card is incorrect or the card itself is defective. The first thing to try is clearing the ESCD in the BIOS Setup. This essentially forces the plug-and-play routines to reconfigure the system, which can resolve any conflicts. If this doesn’t help, try removing and reinstalling the sound card drivers. Finally, if that doesn’t help, physically remove and replace the card from the system. You might try replacing it first in the same slot and then in a different slot because timing issues can sometimes exist from
Chapter 23
PC Diagnostics, Testing, and Maintenance

one slot to the next. If that doesn’t work, you must try replacing the card. If the sound “card” really isn’t a card but is integrated into the motherboard, first try the ESCD reset and driver reinstallation. Then, if that doesn’t work, you have to try disabling the integrated sound and perhaps installing a replacement card or replacement motherboard.

If your problem is only with playing audio CDs, check for a cable between the sound card and the drive. If there is no cable, check the properties for the drive in the Device Manager in Windows to see whether the Digital CD Audio option is checked (enabled). If it’s not, enable it. If your system will not allow digital CD audio to be enabled, it is not supported and you must install an analog cable connected between the sound card and the drive.

The monitor appears completely garbled or unreadable.

A completely garbled screen is most often due to improper, incorrect, or unsupported settings for the refresh rate, resolution, or color depth. Using incorrect drivers can also cause this. To check the configuration of the card, the first step is to power on the system and verify whether you can see the POST or the system splash screen and enter the BIOS Setup. If the screen looks fine during the POST but goes crazy after Windows starts to load, the problem is almost certainly due to an incorrect setting or configuration of the card. To resolve this, boot the system in Windows Safe mode (hold down the F8 function key as Windows starts to load). This bypasses the current video driver and settings and places the system in the default VGA mode supported by the BIOS on the video card. When the Windows desktop appears, you can right-click the desktop, select Properties, and then either reconfigure the video settings or change drivers as necessary.

If the problem occurs from the moment you turn on the system—and even if you boot to a DOS floppy (such as a Windows 98 startup floppy)—a hardware problem definitely exists with the video card, cable, or monitor. First, replace the monitor with another one; if the cable is detachable, replace that, too. If replacing the monitor and cable does not solve the problem, the video card is probably defective. Either replace the card or, if it is a PCI-based card, move it to a different slot. If the video is integrated into the motherboard, you must add a separate card instead or replace the motherboard.

The image on the display is distorted (bent), shaking, or wavering.

This can often be caused by problems with the power line, such as an electric motor, an air conditioner, a refrigerator, and so on causing interference. Try replacing the power cord, plugging the monitor and/or the system into a different outlet, or moving it to a different location entirely. I’ve also seen this problem caused by local radio transmitters such as a nearby radio or television station or two-way radios being operated in the vicinity of the system. If the monitor image is bent and discolored, it could be due to the shadow mask being magnetized. Turn the monitor on and off repeatedly; this causes the built-in degaussing coil around the perimeter of the tube to activate in an attempt to demagnetize the shadow mask. If this seems to work partially but not completely, you might need to obtain a professional degaussing coil from an electronics or TV service shop to demagnetize the mask. Next, replace the monitor cable, try a different (known-good) monitor, and finally replace the video card.

I purchased an upgraded AGP video card, and it won’t fit in the slot.

Most newer AGP video cards are designed to conform to the AGP 4X or AGP 8X specification, both of which run on only 1.5 volts. Most older motherboards with AGP 2X slots are designed to accept only 3.3V cards. If you were to plug a 1.5V card into a 3.3V slot, both the card and motherboard could be damaged. Special keys have therefore been incorporated into the AGP specification to prevent such disasters. Typically, the slots and cards are keyed such that 1.5V cards fit only in 1.5V sockets and 3.3V cards fit only in 3.3V sockets. Additionally, universal sockets are available that accept either 1.5V or 3.3V cards. The keying for the AGP cards and connectors is dictated by the AGP standard as shown in Figure 23.12.
Figure 23.12  AGP 4X/8X (1.5V) card and how it relates to 3.3V, universal, and 1.5V AGP slots.

As you can see from Figure 23.12, AGP 4X or 8X (1.5V) cards fit only in 1.5V or universal (3.3V or 1.5V) slots. Due to the design of the connector and card keys, a 1.5V card cannot be inserted into a 3.3V slot. So, if your new AGP card won't fit in the AGP slot in your existing motherboard, consider that a good thing because, if you were able to plug it in, you would have fried both the card and the board! In a case such as this, you have to either return the 4X/8X card or get a new motherboard that supports 4X/8X (1.5V) cards.

I installed an upgraded processor, but it won't work.

First, make sure the motherboard supports the processor that is installed. Also make sure you are using the latest BIOS for your motherboard; check with the motherboard manufacturer to see whether any updates are available for download, and install them if any are available. Check the jumper settings (older boards) or BIOS Setup screens to verify that the processor is properly identified and set properly with respect to the FSB (or CPU bus) speed, clock multiplier, and voltage settings. Make sure the processor is set to run at its rated speed and is not overclocked. If any of the CPU settings in the BIOS Setup are on manual override, set them to automatic instead. Then reseat the processor in the socket.

Next, make sure the heatsink is properly installed and you are using thermal interface material (that is, thermal grease) at the mating junction between the CPU and heatsink.

Just because a processor fits in the socket (or slot) on your motherboard does not mean it will work. For a processor to work in a system, the following things are required:

■ **The CPU must fit in the socket.** Most Pentium 4 and newer Celeron processors use Socket 478; Pentium III and older Celerons use Socket 370; and Athlon/Duron processors use Socket 462 (also called Socket A).

■ **The motherboard must support the voltage required by the CPU.** Modern motherboards set voltages by reading voltage ID (VID) pins on the processor and then setting the onboard voltage regulator module (VRM) to the appropriate settings. Older boards might not support the generally lower voltage requirements of newer processors.

■ **The motherboard ROM BIOS must support the CPU.** Modern boards also read the CPU to determine the proper FSB (or CPU bus) speed settings as well as the clock multiplier settings for the CPU. Many CPUs have different requirements for cache settings and initialization, as well as for bug fixes and workarounds.

■ **The motherboard chipset must support the CPU.** In some cases, specific chipset models or revisions might be required to support certain processors.
Before purchasing an upgraded processor for your system, you should first check with the motherboard manufacturer to see whether your board supports the processor. If so, it will meet all the requirements listed previously. Often, BIOS updates are available that enable newer processors to be supported in older boards, beyond what was originally listed in the manual when you purchased the board. The only way to know for sure is to check with the motherboard manufacturer for updated information regarding supported processors for a particular board.

As a specific example, newer versions of the Pentium 4 support hyper threading (HT) technology (one processor acts as if it were two processors, increasing performance). It would be great to purchase one of these new processors as an upgrade for an existing Pentium 4 system. Unfortunately, many existing boards do not accept these new processors. If you are considering replacing an existing Pentium 4 with a new HT technology version, you need to verify that the motherboard supports this processor. Specifically, the board must have one of the more recent chipsets, support the 533MHz or 800MHz FSB speed required by the chip, and incorporate a setting in the BIOS Setup to enable or disable the HT technology. Some preexisting boards might be capable of doing this with only a BIOS upgrade, but other boards do not meet the chipset and FSB requirements. In that case, you need a new processor and motherboard together to upgrade.

**The system runs fine for a few minutes but then freezes or locks up.**

This is the classic symptom of a system that is overheating. Most likely the CPU is overheating, but other components such as the video card or motherboard chipset can also be overheating. If the system is new or custom built, the design might be insufficient for proper cooling, and bigger heatsinks, more fans, or other solutions might be required. If the system was working fine but now is exhibiting this problem, check to see whether the problem started after any recent changes were made. If so, then whatever change was made could be the cause of the problem. If no changes were made, most likely something such as a cooling fan is either failed or starting to fail.

Modern systems should have several fans, one inside the power supply, one on the CPU (or positioned to blow on the CPU), and optionally others for the chassis. Verify that any and all fans are properly installed and spinning. They should not be making grinding or growling noises, which usually indicates bearing failure. Many newer systems have thermostatically controlled fans; in these systems it is normal for the fan speeds to change with the temperature. Make sure that the chassis is several inches from walls and that the fan ports are unobstructed. Try removing and reseating the processor; then reinstall the CPU heatsink with new thermal interface material. Check the power supply and verify that it is rated sufficiently to power the system (most should be 300 watts or more). Use a digital multimeter to verify the voltage outputs of the power supply, which should be within +/–5% of the rated voltage at each pin. Try replacing the power supply with a high-quality replacement or known-good spare.

**I am experiencing intermittent problems with the hard drive(s).**

Most systems use ATA (AT-Attachment, commonly called IDE) interface drives, which consist of a drive and integrated controller, a ribbon cable, and a host adapter circuit in the motherboard. Typically, intermittent problems are found with the cable and the drive—it is far more rare that the host adapter fails or exhibits problems. Many problems occur with the cables. ATA drives use either 40-conductor or 80-conductor cables, with one 40-pin connector at either end and optionally one in the middle. Drives supporting transfer rates higher than ATA-33 (33MBps or Ultra DMA Mode 2) must use 80-conductor cables. Check the cable to ensure that it is not cut or damaged; then try unplugging and replugging it into the drive and motherboard. Check to see that the cable is not more than 18” (46cm) in length because that is the maximum allowed by the ATA specification. This is especially important when you are using the faster ATA-100 or ATA-133 transfer rates. Try replacing the cable with a new 80-conductor 18” version.
If replacing the cable does not help, replace the drive with a spare, install an OS, and test it to see whether the problem remains. If the problem does remain, the problem is with the motherboard, which will most likely need to be replaced. If the problem does not remain, the problem is most likely with your original drive. You can simply replace it or try testing, formatting, and reinstalling to see whether the drive can be repaired. To do this, you need the low-level format or test software provided by the drive manufacturer. You can find out more about where to get this for various makes of drives in Chapter 14, “Physical Drive Installation and Configuration.”

**The system won’t boot up; it says Missing operating system on the screen.**

When your system boots, it reads the first sector from the hard disk—called the master boot record (MBR)—and runs the code contained in that sector. The MBR code then reads the partition table (also contained in the MBR) to determine which partition is bootable and where it starts. Then it loads the first sector of the bootable partition—called the volume boot record (VBR)—which contains the operating-system-specific boot code. However, before executing the VBR, the MBR checks to ensure that the VBR ends with the signature bytes 55AAh. The *Missing operating system* message is displayed by the MBR if it finds that the first sector of the bootable partition (the VBR) does not end in 55AAh.

Several things can cause this to occur, including these:

- **The drive parameters entered in the BIOS Setup are incorrect or corrupted.** These are the parameters defining your drive that you entered in the BIOS Setup, and they’re stored in a CMOS RAM chip powered by a battery on your motherboard. Incorrect parameters cause the MBR program to translate differently and read the wrong VBR sector, thus displaying the *Missing operating system* message. A dead CMOS battery can also cause this because it loses or corrupts the stored drive translation and transfer mode parameters. In fact, in my experience, a dead battery is one of the more likely causes. To repair, check, and replace the CMOS battery, run the BIOS Setup, go to the hard drive parameter screen, and enter the correct drive parameters. Note that most drive parameters should be set to auto or auto-detect.

- **The drive is not yet partitioned and formatted on this system.** This is a normal error if you try to boot the system from the hard disk before the OS installation is complete. Boot to an OS startup disk (floppy or CD), and run the SETUP program, which will prompt you through the partitioning and formatting process during the OS installation.

- **The MBR and/or partition tables are corrupt.** This can be caused by boot sector viruses, among other things. To repair this, cold boot (power off, then on) from a known, noninfected, write-protected floppy or bootable CD containing the FDISK program (preferably Win98 or later). Enter `FDISK /MBR` at the command prompt, which recopies the MBR code but doesn’t alter the partition table. Then reboot. If the message persists, and you need to recover the data on the drive, you then must either rebuild the partition tables from scratch using a third-party utility such as the DISKEDIT program included with the Symantec Norton Utilities or hire a data recovery specialist who can do this for you. If you don’t need to recover the data on the drive, simply reinstall the OS from scratch, which will prompt you through partitioning and formatting the drive.

- **The VBR is corrupt.** To repair with Windows 95/98/Me, secure a bootable floppy that was created by the same OS version as is on the hard disk and that contains the SYS command from that OS. Run `SYS C:`; which recopies a good VBR and system files to the volume. For Windows NT/2000/XP, you can use the Recovery Console or DiskProbe utilities (found on the bootable operating system CD).

**The system is experiencing intermittent memory errors.**

If the memory was recently added or some other change was made to the system, you should undo that addition/change to see whether it is the cause. If it’s not, remove and reseat all memory modules. If the contacts look corroded, clean them with contact cleaner and then apply contact enhancer for protection.
Check the memory settings in the BIOS Setup; generally, all settings should be on automatic. Next, upgrade to the latest BIOS for your motherboard, and remove all memory except one bank. Then run only one bank of memory, but in the second or third bank position. A socket can develop a problem, and most motherboards do not require that the sockets be filled in numerical order. Also, replace the remaining module with one of the others that was removed, a new module, or a known-good spare.

If you get this far, the problem is most likely either the motherboard or the power supply—or possibly some other component in the system. Remove other components from the system to see whether they are causing problems. Reset the CPU, and replace the power supply with a high-quality new unit or a known-good spare. Finally, try replacing the motherboard.

**The system locks up frequently and sometimes reboots on its own.**

This is one of the classic symptoms of a power supply problem. The power supply is designed to send a special Power_Good signal to the motherboard when it has passed its own internal tests and outputs are stable. If this signal is dropped, even for an instant, the system resets. Problems with the power good circuit cause lockups and spontaneous rebooting. This can also be caused if the power at the wall outlet is not correct. Verify the power supply output with a digital multimeter—all outputs should be within +/-5% of the rated voltages. Use a tester for the wall outlet to ensure that it is properly wired, and verify that the voltage is near 120V. Replace the power cord or power strip between the power supply and wall outlet.

Unfortunately, the intermittent nature makes this problem hard to solve. If the problem is not with the wall outlet power, the best recourse is to replace the power supply with a high-quality new unit or a known-good spare of sufficient rating to handle the system (300 watts or higher recommended). If this doesn't help, reseat the CPU and reinstall the heatsink with new thermal interface material. Then reseat the memory modules, run only one bank of memory, and finally replace the motherboard.

**I installed a 60GB drive in my system, but it is recognizing only 8.4GB.**

Motherboard ROM BIOSs have been updated throughout the years to support larger and larger drives. BIOSs older than August 1994 are typically limited to drives of up to 528MB, whereas BIOSs older than January 1998 are limited to 8.4GB. Most BIOSs dated 1998 or newer support drives up to 137GB, and those dated September 2002 or newer should support drives larger than 137GB. These are only general guidelines; to accurately determine this for a specific system, you should check with your motherboard manufacturer. You can also use the BIOS Wizard utility from [www.unicore.com/bioswiz/index2.html](http://www.unicore.com/bioswiz/index2.html). It tells you the BIOS date from your system and specifically whether your system supports the Enhanced Hard Disk Drive specification, which means drives larger than 8.4GB.

If your BIOS does not support EDD (drives larger than 8.4GB), the three possible solutions are as follows:

- Upgrade your motherboard BIOS upgrade to a 1998 or newer version that supports >8.4GB.
- Install a BIOS upgrade card, such as the ATA Pro Flash from [www.firmware.com](http://www.firmware.com) or the Ultra ATA 133 PCI card from [www.maxtordirect.com](http://www.maxtordirect.com).
- Install a software patch to add >8.4GB support.

Of these, the first one is the most desirable because it is usually free. Visit your motherboard manufacturer’s Web site to see whether it has any newer BIOSs available for your motherboard that will support large drives. If it doesn’t, the next best thing is to use a card such as the ATA Pro Flash from MicroFirmware or the Ultra ATA 133 PCI card from Maxtor. I almost never recommend the software patch solution because it merely installs a special driver in the boot sector area of the hard drive, which can result in numerous problems when booting from different drives, installing new drives, or recovering data.
The 137GB barrier is a bit more complicated because, in addition to BIOS issues, operating system and chipset-based ATA host adapter driver issues are involved. Drives larger than 137GB are accessed using 48-bit logical block address (LBA) numbers, which require BIOS support, chipset driver support, and operating system support. Generally, you need a BIOS with 48-bit LBA support (normally dated September 2002 or newer), the latest chipset driver such as the Intel Application Accelerator (for motherboards using Intel chipsets, at www.intel.com/support/chipsets/iaa), and Windows XP with Service Pack 1 (or later) installed. If your motherboard BIOS does not provide the necessary support, the Maxtor Ultra ATA 133 PCI card listed earlier adds this support to your system. The original version of XP, as well as Windows 2000/NT or Windows 95/98/Me, does not currently provide native support for hard drives larger than 137GB.

If you have a system without BIOS support, check with your motherboard manufacturer for an update (or you can use a card with onboard BIOS, such as the Ultra ATA 133 PCI card from Maxtor). If your motherboard uses a non-Intel chipset, check with the motherboard or chipset manufacturer for driver updates to enable 48-bit LBA support.

**My CD-ROM/DVD drive doesn’t work.**

CD and DVD drives are some of the more failure-prone components in a PC. It is not uncommon for one to suddenly fail after a year or so of use.

If you are having problems with a drive that was newly installed, check the installation and configuration of the drive. Check the jumper settings on the drive. If you're using an 80-conductor cable, the drive should be jumpered to Cable Select; if you're using a 40-conductor cable, the drive should be set to either master or slave (depending on whether it is the only drive on the cable). Check the cable to ensure that it is not nicked or cut and is a maximum of 18" long (the maximum allowed by the ATA specification). Replace the cable with a new one or a known-good spare, preferably using an 80-conductor cable. Make sure the drive power is connected, and verify that power is available at the connector using a digital multimeter. Also make sure the BIOS Setup is set properly for the drive, and verify that the drive is detected during the boot process. Finally, try replacing the drive and, if necessary, the motherboard.

If the drive had already been installed and was working before, first read different discs, preferably commercial-stamped discs rather than writeable or rewriteable ones. Then try the steps listed previously.

**My USB port or device doesn’t work.**

Make sure you have enabled the USB ports in the BIOS Setup. Make sure your operating system supports USB—Windows 95 and NT do not, whereas Windows 98 and later do have USB support. Then remove any hubs and plug the device directly into the root hub connections on your system. Replace the cable. Many USB devices require additional power, so ensure that your device has an eternal power supply connected if one is required. Replace the power supply.

**I installed an additional memory module, but the system doesn’t recognize it.**

Verify that the memory is compatible with your motherboard. Many subtle variations exist on memory types that can appear to be identical on the surface. Just because it fits in the slot does not mean the memory will work properly with your system. Check your motherboard manual for the specific type of memory your system requires, and possibly for a list of supported modules. You can visit www.crucial.com and use its memory selector to determine the exact type of memory for a specific system or motherboard. Also note that all motherboards have limits to the amount of memory they support, and many boards today support only up to 512MB or 1GB. Again, consult the motherboard manual or manufacturer for information on the limits for your board.

If you are sure you have the correct type of memory, follow the memory troubleshooting steps listed previously for intermittent memory problems.
I installed a new drive, but it doesn’t work and the drive LED remains lit.

This is the classic symptom for a cable plugged in backward. Both ATA and floppy drives are designed to use cables with keyed connectors; however, some cables are available that lack this keying, which means they can easily be installed backward. When the cable is installed backward into either the motherboard or the drive, the LED on the drive remains lit and the drive does not function. In some cases, this can also cause the entire system to freeze. Check the cables to ensure that they are plugged in properly at both ends; the stripe on the cable indicates pin-1 orientation. On the drive, pin-1 typically is oriented toward the power connector. On the motherboard, look for orientation marks silk-screened on the board or observe the orientation of the other cables plugged in (all cables follow the same orientation).

While I was updating my BIOS, the system froze and now the system is dead!

This can occur when a flash ROM upgrade goes awry. Fortunately, most motherboards have a recovery routine that can be enabled via a jumper on the board. When enabled, the recovery routine causes the system to look for a floppy with the BIOS update program on it. If you haven’t done so already, you need to download an updated BIOS from the motherboard manufacturer and follow its directions for placing the BIOS update program on a bootable floppy. Then set BIOS recovery mode via the jumper on the motherboard, power on the system, and wait until the procedure completes. It usually take up to 5 minutes, and you might hear beeping to indicate the start and end of the procedure. When the recovery is complete, turn off the system and restore the recovery jumper to the original (normal) settings.

If your motherboard does not feature BIOS recovery capability, you might have to send the board to the manufacturer for repair.

I installed a new motherboard in an older Dell system, and nothing works.

Many older Dell Dimension systems (Dimension 4100, 8100, or older systems) do not fully conform to the ATX specification with respect to their power supplies and the power connectors on their motherboards. If you replace one of these nonstandard Dell power supplies with a standard ATX type, or replace the nonstandard Dell motherboard with a standard ATX type, you risk frying both the power supply and the motherboard. The older Dell systems can be upgraded only by replacing both the motherboard and the power supply at the same time.

Starting in 2001, Dell converted to using industry-standard ATX power supplies and motherboard power connectors for its systems, so this should not be a problem for the Dimension 4200, 8200, and later machines.

I installed a PCI video card in an older system with PCI slots, and it doesn’t work.

The PCI bus has gone through several revisions; most older slots are “2.0” type, and most newer cards need “2.1” or later PCI slots. The version of PCI your system has is dictated by the motherboard chipset. If you install a newer video or other PCI card that requires 2.1 slots in a system with 2.0 slots, often the system won’t boot up or operate at all.

If you check the chipset reference information in Chapter 4, you might be able to determine which revision of PCI slots your motherboard has by knowing which chipset it has. If this is your problem, the only solution is to change either the card or motherboard so that they are both compatible.
File Systems

Physically, the hard disks and other media provide the basic technology for storing data. Logically, however, the file system provides the hierarchical structure of volumes and directories in which you store individual files and the organizational model that enables the system to locate data anywhere on a given disk or drive. File systems typically are an integrated part of an operating system (OS), and many of the newer OSes provide support for several file systems from which you can choose.

Several file systems are available from which to choose in a modern PC. Each file system has specific limitations, advantages, and disadvantages, and which ones you use can also be limited by the operating system you choose. Not all operating systems support all the file systems.

The primary file systems to choose from today include

- File allocation table (FAT), which includes FAT12, FAT16, and FAT32
- New Technology File System (NTFS)

Although other file systems, such as OS/2's High Performance File System (HPFS), are in use on PCs, these are the two you're most likely to find on a Windows-based PC. Consequently, this chapter focuses mainly on FAT and NTFS.

File Allocation Table

Until the release of Windows XP, the most commonly used file systems were based on a file allocation table (FAT), which keeps track of the data stored in each cluster on a disk. FAT is still the most universally understood file system, meaning it is recognized by virtually every operating system that runs on PCs, and even non-PCs. For example, FAT is even recognizable on Apple Mac systems. For this reason, although NTFS (covered later in this chapter) is usually recommended with Windows XP, for greater compatibility across systems and platforms, most external hard disks and removable-media drives use FAT as their native file systems. Also, if you want to dual-boot Windows XP and Windows 9x/Me, you need to use FAT-based file systems even on your main drives.

Three main varieties of the FAT system exist, called FAT12, FAT16, and FAT32—all of which are differentiated by the number of digits used in the allocation table numbers. In other words, FAT16 uses 16-bit numbers to keep track of data clusters, FAT32 uses 32-bit numbers, and so on. The various FAT systems are used as follows:

- **FAT12.** Used on all volumes smaller than 16MiB (for example, floppy disks).
- **FAT16.** Used on volumes from 16MiB through 2GiB by MS-DOS 3.0 and most versions of Windows. Windows NT, Windows 2000, and Windows XP support FAT16 volumes as large as 4GiB. However, FAT16 volumes larger than 2GiB cannot be used by MS-DOS or Windows 9x/Me.
- **FAT32.** Optionally used on volumes from 512MiB through 2GiB, and required on all FAT volumes over 2GiB, starting with Windows 95B (OSR 2.x) and subsequent versions.

FAT12 and FAT16 are the file systems originally used by DOS and Windows and are supported by every other PC operating system from past to present. An add-on to the FAT file systems called VFAT is found in Windows 95 and newer. VFAT is a driver in Windows that adds the capability to use long filenames on existing FAT systems. When running Windows 95 or newer, VFAT is automatically enabled for all FAT volumes.

Although all PC operating systems support FAT12 and FAT16, Windows 2000 and XP also have support for FAT32 as well as non-FAT file systems such as NTFS.
FAT12

FAT12 was the first file system used in the PC when it was released on August 12, 1981, and it is still used today on all floppy disks and FAT volumes less than 16MiB. FAT12 uses a table of 12-bit numbers to manage the clusters (also called allocation units) on a disk. A cluster is the storage unit in the data area of the disk where files are stored. Each file uses a minimum of one cluster, and files that are larger than one cluster use additional space in cluster increments. FAT12 cluster sizes are shown in Table 24.1.

### Table 24.1  FAT12 Cluster Sizes

<table>
<thead>
<tr>
<th>Media Type</th>
<th>Volume Size</th>

</tbody>
</table>

**DD = Double density**  
**HD = High density**  
**ED = Extra-high density**  
**KiB = Kibibyte = 1,024 bytes**  
**MiB = Mebibyte = 1,048,576 bytes**

Each cluster on a FAT12 volume is typically 8 sectors in size, except on floppy disks, where the size varies according to the particular floppy type. 12-bit cluster numbers range from 000h to FFFh (hexadecimal), which is 0–4,095 in decimal. This theoretically allows 4,096 total clusters; however, 11 of the cluster numbers are reserved and cannot be assigned to actual clusters on a disk. Cluster numbers start at 2 (0 and 1 are reserved), number FF7h is reserved to indicate a bad cluster, and numbers FF8h–FFFh indicate an end-of-chain in the FAT, leaving 4,085 clusters (4,096 – 11 = 4,085). Microsoft subtracts 1 from this to eliminate boundary problems, allowing up to exactly 4,084 clusters maximum in a FAT12 volume.

FAT12 volumes include 1 sector for the boot record and BPB (BIOS parameter block), two copies of the FAT (up to 12 sectors long each), up to 32 sectors for the root directory (less only on floppy disk media), and a data area with up to 4,084 clusters. Because each FAT12 cluster is 8 sectors (except on floppy disks), FAT12 volumes are limited to a maximum size of 32,729 sectors (1 sector for the boot record + 12 sectors per FAT × 2 FATs + 32 sectors for the root directory + 4084 clusters × 8 sectors per cluster). This equals 16.76MB or 15.98MiB. FAT12 volume limits are detailed in Table 24.2.

### Table 24.2  FAT12 Volume Limits

<table>
<thead>
<tr>
<th>Volume Limit</th>
<th>Clusters</th>
<th>Sectors per Cluster</th>
<th>Total Volume Sectors</th>
<th>Volume Size (Decimal)</th>
<th>Volume Size (Binary)</th>

<td>Maximum size</td>
<td>4,084</td>
<td>8</td>
<td>32,729</td>
<td>16.76MB</td>
<td>15.98MiB</td>
</tr>
</tbody>
</table>

**MB = Megabyte = 1,000,000 bytes**  
**MiB = Mebibyte = 1,048,576 bytes**

PC/MS-DOS 1.x and 2.x use FAT12 exclusively, and all later versions of DOS and all Windows versions automatically create a FAT12 file system on any disks or partitions that are 32,729 sectors or less (16.76MB) in size. Anything larger than that is automatically formatted as FAT16, FAT32, or NTFS. Characteristics of FAT12 include the following:

- Is used on all floppy disks
- Has a default format on FAT volumes of 16.76MB (15.98MiB) or less
FAT12 is still used in PCs today on very small media because the 12-bit tables are smaller than those for FAT16 and FAT32, which preserves the most space for data.

**FAT16**

FAT16 is similar to FAT12 except it uses 16-bit numbers to manage the clusters on a disk. FAT16 was introduced on August 14, 1984, along with PC/MS-DOS 3.0, with the intention of supporting larger hard drives. FAT16 picked up where FAT12 left off and was used on media or partitions larger than 32,729 sectors (15.98MiB or 16.76MB). FAT16 could theoretically support drives of up to 2GiB or 4GiB. However, even with FAT16, DOS 3.3 and earlier were still limited to a maximum partition size of 32MiB (33.55MB) because DOS 3.3 and earlier used only 16-bit sector addressing internally and in the BPB (BIOS parameter block, stored in the volume boot sector, which is the first logical sector in a FAT partition). The use of 16-bit sector values limited DOS 3.3 and earlier to supporting drives of up to 65,535 sectors of 512 bytes, which is 32MiB (33.55MB).

As a temporary way to address drives larger than 32MiB, PC/MS-DOS 3.3 (released on April 2, 1987) introduced the extended partition, which could internally support up to 23 subpartitions (logical drives) of up to 32MiB each. Combined with the primary partition on a disk, this allowed for a total of 24 partitions of up to 32MiB each, which would be seen by the operating system as logical drives C–Z.

To take full advantage of FAT16 and allow for larger drives and partition sizes, Microsoft collaborated with Compaq, who introduced Compaq DOS 3.31 in November 1987. It was the first OS to use 32-bit sector addressing internally and in the BPB. Then the rest of the PC world followed suit on July 19, 1988, when Microsoft and IBM released PC/MS-DOS 4.0. This enabled FAT16 to handle partition sizes up to 2GiB using 64 sectors per cluster.

Each cluster in a FAT16 volume is up to 64 sectors in size. 16-bit cluster numbers range from 0000h to FFF7h, which is 0–65,535 in decimal. This theoretically allows 65,536 total clusters. However, 11 of the cluster numbers are reserved and cannot be assigned to actual clusters on a disk. Cluster numbers start at 2 (0 and 1 are reserved), number FFF7h is reserved to indicate a bad cluster, and numbers FFF8h–FFFFh indicate an end of chain in the FAT, leaving 65,525 clusters (65,536 – 11 = 65,525).

Microsoft subtracts 1 from this to eliminate boundary problems, allowing up to 65,524 clusters maximum in a FAT16 volume. FAT16 cluster sizes are shown in Table 24.3.

<table>
<thead>
<tr>
<th>Volume Size</th>
<th>Sectors per Cluster</th>
<th>Cluster Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>4.1MiB–15.96MiB¹</td>
<td>2</td>
<td>1KiB</td>

<td>128</td>
<td>64KiB</td>
</tr>
</tbody>
</table>

1. Volumes smaller than 16MiB default to FAT12; however, FAT32 can be forced by altering the format parameters.
2. Volumes larger than 2GiB are supported only by Windows NT/2000/XP and are not recommended.

---

MB = Megabyte = 1,000,000 bytes
KiB = Kibibyte = 1,024 bytes
MiB = Mebibyte = 1,024KiB = 1,048,576 bytes
GiB = Gibibyte = 1,024MiB = 1,073,741,824 bytes
FAT16 volumes include 1 sector for the boot record and BPB, two copies of the FAT (default and backup) up to 256 sectors long each, 32 sectors for the root directory, and a data area with 4,085–65,524 clusters. Each FAT16 cluster can be up to 64 sectors (32KiB) in size, meaning FAT16 volumes are limited to a maximum size of 4,194,081 sectors (1 sector for the boot record + 256 sectors per FAT × 2 FATs + 32 sectors for the root directory + 65,524 clusters × 64 sectors per cluster). This equals a maximum capacity of 2.15GB or 2GiB. FAT16 volume limits are shown in Table 24.4.

**Note**

Windows NT/2000/XP can optionally create FAT16 volumes that use 128 sectors per cluster (64KiB) in size, bringing the maximum volume size to 4.29GB or 4GiB. However any volumes formatted in that manner are not readable in virtually any other OS. Additionally, 64KiB clusters cause many disk utilities to fail. For maximum compatibility, FAT16 volumes should be limited to 32KiB clusters and 2.15GB/2GiB in size.

MB = Megabyte = 1,000,000 bytes  
MiB = Mebibyte = 1,048,576 bytes  
GB = Gigabyte = 1,000  
GiB = Gibibyte = 1,024MiB = 1,073,741,824 bytes  
MB = 1,000,000,000 bytes

Some notable characteristics and features of FAT16 include

- FAT16 is fully supported by MS-DOS 3.31 and higher, all versions of Windows, and some Unix operating systems.
- FAT16 is fast and efficient on volumes smaller than 256MiB but relatively inefficient on larger volumes because the cluster size becomes much larger than with FAT32 and NTFS.
- The boot sector information is not automatically backed up, and if damaged or destroyed, access to the volume is lost.
- In case of a problem, you can boot the system using any MS-DOS bootable floppy to troubleshoot the problem and if necessary, repair the volume. Many third-party software tools can repair or recover data from FAT16 volumes.
- The root directory (folder) can handle up to a maximum of 512 entries, which is further reduced if any root entries use long filenames.
- FAT16 has no built-in security, encryption, or compression capability.
- File sizes on a FAT16 volume are limited only by the size of the volume. Because each file takes a minimum of one cluster, FAT16 volumes cannot have more than 65,524 total files.

### FAT32

FAT32 is an enhanced version of the FAT file system first supported by Windows 95B (also known as OEM Service Release 2, released in August 1996). FAT32 is also supported in Windows 98/Me and Windows 2000/XP. FAT32 is not supported in the original release of Windows 95 or in any release of Windows NT.
One of the main reasons for creating FAT32 was to use disk space more efficiently. FAT32 uses smaller clusters (4KiB clusters for drives up to 8GiB in size), resulting in a 10%–15% more efficient use of disk space relative to large FAT16 drives. FAT32 also supports partitions of up to 2TiB in size, much larger than the 2GiB limit of FAT16. FAT32 cluster sizes are shown in Table 24.5.

1. Volumes smaller than 512MiB will default to FAT16, although FAT32 can be forced by altering the format parameters.
2. Windows 2000 and XP format FAT32 volumes only up to 32GiB; however, they support existing FAT32 volumes up to 2TiB.

Although the name implies that FAT32 uses 32-bit numbers to manage clusters (allocation units) on a disk, FAT32 actually uses only the first 28 bits of each 32-bit entry, leaving the high 4 bits reserved. The only time the high 4 bits are changed is when the volume is formatted, at which time the whole 32-bit entry is zeroed (including the high 4 bits). The high 4 bits are subsequently ignored when reading or writing FAT32 cluster entries; therefore, if those bits are non-zero, they are preserved. Microsoft has never indicated any purpose for them other than simply being reserved.

So, although the entries are technically 32-bit numbers, FAT32 really uses 28-bit numbers to manage the clusters on a disk. Each cluster on a FAT32 volume is from 1 sector (512 bytes) to 64 sectors (32KiB) in size. 28-bit cluster numbers range from 0000000h to FFFFFFFh, which is 0–268,435,455 in decimal. This theoretically allows for 268,435,456 total clusters. However 11 of the numbers are reserved and cannot be assigned to actual clusters on a disk. Cluster numbers start at 2 (0 and 1 are reserved), the number FFFFFFF7h is reserved to indicate a bad cluster, and numbers FFFFFFF8h–FFFFFFFh indicate an end of chain in the FAT, leaving exactly 268,435,445 clusters maximum (268,435,456 – 11 = 268,435,445).

FAT32 volumes reserve the first 32 sectors for the boot record, which includes both the default boot record (3 sectors long, starting at logical sector 0) and a backup boot record (also 3 sectors long, but starting at logical sector 6). The remaining sectors in that area are reserved and filled with 0s. Following the 32 reserved sectors are 2 FATs (default and backup) that can be anywhere from 512 sectors to 2,097,152 sectors in length, with a data area 65,525–268,435,445 clusters.

Each FAT32 cluster is up to 64 sectors (32KiB) in size, so FAT32 disks or partitions could theoretically be up to 17,184,062,816 sectors (32 sectors for the boot record + 2,097,152 sectors per FAT × 2 FATs + 268,435,445 clusters × 64 sectors per cluster), which equals a capacity of 8.8TB or 8TiB. This capacity is theoretical because the 32-bit sector numbering scheme used in the partition tables located in the master boot record (MBR) limits a disk to no more than 4,294,967,295 (2³²–1) sectors, which is 2.2TB or 2TiB. Therefore, although FAT32 can in theory handle a volume of up to 8.8TB (terabytes or trillions of bytes), the reality is that we are currently limited by the partition table format of the MBR to only 2.2TB. At the current rate of hard disk capacity growth, single drives of that size will debut between the years 2009 and 2011. Of course, by that time the MBR limitation should be addressed.
Note
If you attempt to format a FAT32 volume larger than 32GiB on a system running Windows 2000 or Windows XP, the format fails near the end of the process with the following error:

Logical Disk Manager: Volume size too big.

This is by design. The format tools included with Windows 2000 and XP will not format a volume larger than 32GiB using the FAT32 file system. Only the format tools are restricted as such; any preexisting volumes up to 2TiB are otherwise fully supported. Microsoft is attempting to force you to use NTFS on any newly created volumes larger than 32GiB. If you are formatting an external USB or FireWire drive that will be moved between various systems, some of which include Windows 98 or Me, you must format the drive on a Windows 98 or Me system.

Windows 95 OSR2 and Windows 98 have additional limitations with FAT32. The ScanDisk tool included with those operating systems is a 16-bit program that has a maximum allocation size for a single memory block of 16MB less 64KB. This means that ScanDisk cannot process volumes using the FAT32 file system that have a FAT larger than 16MB less 64KB in size. Each FAT32 entry uses 4 bytes, so ScanDisk cannot process the FAT on a volume using the FAT32 file system that defines more than 4,177,920 clusters, which after subtracting the two reserved clusters leaves 4,177,918 actual clusters. At 32KiB per cluster—including the boot sector reserved area and the FATs themselves—this results in a maximum volume size of 136.94GB or 127.53GiB. Windows Me and later do not have this limitation.

Table 24.6 lists the volume limits for a FAT32 file system.

FAT32 is more robust than FAT12 or FAT16. FAT12/16 uses the first sector of a volume for the volume boot record, which is a critical structure. If the boot sector is damaged or destroyed, access to the entire volume is lost. FAT32 improves on this by creating both a default and a backup volume boot record in the first 32 sectors of the volume, which are reserved for this purpose. Each FAT32 volume boot record is 3 sectors long. The default boot record is in logical sectors 0–2 (the first three sectors) in the partition, and the backup is in sectors 6–8. This feature has saved me on several occasions when the default boot record was damaged and access to the entire volume was lost. In these situations, I was still able to recover the entire volume by manually restoring the volume boot record from the backup by using a sector editor such as Norton Diskedit (included with Norton SystemWorks by Symantec). Because FAT12 and FAT16 do not create a backup boot sector, if the boot sector is destroyed on those volumes, it must be re-created manually from scratch—a much more difficult proposition.

As with FAT12/16, FAT32 also maintains two copies of the FAT and automatically switches to the backup FAT if a sector in the default FAT becomes unreadable. The root directory (folder) in a FAT16 system is exactly 32 sectors long and immediately follows the two FAT copies; however, in FAT32 the root directory is actually created as a subdirectory (folder) that is stored as a file, relocatable to anywhere in the
partition, and extendable in length. Therefore, a 512-file limit no longer exists in the root directory for FAT32 as there was with FAT12/16.

Some notable characteristics and features of FAT32 include the following:

- FAT32 is fully supported by Windows 95B (OSR2), 98, Me, 2000, XP, and later versions.
- MS-DOS 6.22 and earlier, Windows 95a, and Windows NT do not support FAT32 and cannot read or write FAT32 volumes.
- Mac OS 8.1 and later support FAT32 drives.
- FAT32 is the ideal format for large, external USB or FireWire drives that will be moved between various PC and Mac systems.
- The root directory (folder) is stored as a subdirectory file that can be located anywhere on the volume. Subdirectories (folders) including the root can handle up to 65,534 entries, which is further reduced if any entries use long filenames.
- FAT32 uses smaller clusters (4KiB for volumes up to 8GiB), so space is allocated much more efficiently than FAT16.
- The critical boot sector is backed up at logical sector 6 on the volume.
- Windows 2000 and XP format FAT32 volumes only up to 32GiB. To format FAT32 volumes larger than 32GiB, you must format the volume on a Windows 98/Me system.
- In case of a boot problem, you must start the system using a bootable disk created using Windows 95B (OSR2), 98, Me, 2000, or XP. A limited number of third-party software tools can repair or recover data from FAT32 volumes.
- FAT32 has no built-in security, encryption, or compression capability.
- File sizes on FAT32 volumes are limited to 4,294,967,295 bytes \((2^{32} - 1)\), which is 1 byte less than 4GiB in size.

## NTFS

Windows NT 3.1 (the first version of NT despite the 3.1 designation) was released in August 1993 and introduced the New Technology File System (NTFS), which is unique to NT-based operating systems (including Windows 2000 and Windows XP) and is not supported by Windows 9x/Me. NTFS includes many advanced features not found in the FAT file systems.

NTFS supports larger volumes (up to 16TiB), larger files, and more files per volume than FAT. NTFS also uses smaller cluster sizes than even FAT32, resulting in more efficient use of a volume. For example, a 30GiB NTFS volume uses 4KiB clusters, whereas the same size volume formatted with FAT32 uses 16KiB clusters. Smaller clusters reduce wasted space on the volume. NTFS cluster sizes are shown in Table 24.7.

### Table 24.7 NTFS Cluster Sizes

<table>
<thead>

1. Larger cluster sizes can be forced by altering the format parameters; however, file compression is disabled if clusters larger than 8 sectors (4KiB) are selected.

**Conversion**

- TB = Terabyte = 1,000GB = 1,000,000,000,000 bytes
- KiB = Kibibytes = 1,024 bytes
- MiB = Mebibyte = 1,024KiB = 1,048,576 bytes
- GiB = Gibibyte = 1,024MiB = 1,073,741,824 bytes
- TiB = Tebibytes = 1,024GiB = 1,099,511,627,776 bytes

- MB = Megabyte = 1,000,000 bytes
- GB = Gigabyte = 1,000MB = 1,000,000,000 bytes
NTFS uses a special file structure called a master file table (MFT) and metadata files. The MFT is basically a relational database that consists of rows of file records and columns of file attributes. It contains at least one entry for every file on an NTFS volume. NTFS creates file and folder records for each file and folder created on an NTFS volume. These are stored in the MFT and consume 1KiB each. Each file record contains information about the position of the file record in the MFT, as well as file attributes and any other information about the file.

NTFS was designed to manage clusters using up to 64-bit numbers, which is an astronomical amount, but the current implementations use 32-bit numbers instead. Using 32-bit numbers allows for addressing up to 4,294,967,295 clusters, each of which is typically up to 4KiB.

NTFS reserves a total of 32 sectors for a 16-sector-long default volume boot sector and a backup boot sector. The default boot sector is located at the beginning (logical sector 0) of the volume, whereas the backup boot sector is written at the logical center of the volume (if it was formatted using NT 3.51 and earlier) or at end of the volume (if it was formatted with NT 4.0 or later, including 2000 and XP).

An NTFS volume can therefore comprise up to 34,359,738,392 total sectors (32 sectors reserved for the default and backup boot sectors, plus 4,294,967,295 clusters × 8 sectors), which is 17.59TB or 16.00TiB. Note that this capacity is theoretical because the 32-bit sector numbering scheme used in the partition tables located in the MBR limits a disk to no more than 4,294,967,295 (2^{32}–1) sectors, which is 2.2TB or 2TiB. Therefore, even though NTFS can in theory handle a volume of up to 17.59TB, the reality is that this is currently limited by the partition table format of the MBR to only 2.2TB.

Windows 2000 and XP can get around this on nonbootable drives by using a new storage format called a dynamic disk. Windows 2000 and XP Professional (but not XP Home) offer two types of storage: basic disks and dynamic disks. Basic disks use the same structures as before, with an MBR on the disk containing a partition table limited to four primary partitions per disk, or three primary partitions and one extended partition with unlimited logical drives. Primary partitions and logical drives on basic disks are known as basic volumes.

Dynamic disks were first introduced in Windows 2000 and provide the capability to create dynamic volumes that can be simple (using only one drive), spanned (using multiple drives), or striped (using multiple drives simultaneously for increased performance). Dynamic disks use a hidden database (contained in the last megabyte of the disk) to track information about dynamic volumes on the disk and about other dynamic disks in the computer. Because each dynamic disk in a computer stores a replica of the dynamic disk database, a corrupted database on one dynamic disk can be repaired using the database on another. By spanning or striping multiple drives using dynamic disk formats, you can exceed the 2TiB limit of a single MBR-based partition.

Although the 32-bit sector numbering in the partition tables on MBR disks limits NTFS basic disks to 2TiB volumes, you can use dynamic volumes to create NTFS volumes larger than 2TiB by spanning or striping multiple basic disks to create a larger dynamic disk. Because the dynamic volumes are managed in the hidden database, they are not affected by the 2TiB limit imposed by the partition tables in the MBR. In essence, dynamic disks enable Windows 2000 and XP Pro to create NTFS volumes as large as 16TiB. The volume limits for NTFS are listed in Table 24.8.

### Table 24.8 NTFS Volume Limits

**MB = Megabyte = 1,000,000 bytes**

**MiB = Mebibyte = 1,024KiB = 1,048,576 bytes**

**GB = Gigabyte = 1,000MB = 1,000,000,000 bytes**

**GiB = Gibibyte = 1,024MiB = 1,073,741,824 bytes**

**TB = Terabyte = 1,000GB = 1,000,000,000,000 bytes**

**TiB = Tebibytes = 1,024GiB = 1,099,511,627,776 bytes**

**KiB = Kibibytes = 1,024 bytes**
Some notable characteristics and features of NTFS include:

- Files are limited in size to 16TiB less 64KiB or by the size of the volume, whichever is lower. NTFS supports up to 4,294,967,295 ($2^{32}-1$) files on a volume.

- NTFS is not normally used on removable media because NTFS does not flush data to the disk immediately. In addition, removing NTFS-formatted media without using the Safe Removal application can result in data loss. For removable media that can be ejected unexpectedly, you should use FAT12, FAT16, or FAT32 instead.

- NTFS incorporates transaction logging and recovery techniques. In the event of a failure, upon reboot NTFS uses its log file and checkpoint information to restore the consistency of the file system.

- NTFS dynamically remaps clusters found to contain bad sectors and then marks the defective cluster as bad so it will no longer be used.

- NTFS has built-in security features. These enable you to set permissions on a file or folder.

- NTFS has a built-in encrypting File System (EFS). This performs dynamic encryption and decryption as you work with encrypted files or folders, while preventing others from doing so.

- It enables the setting of disk quotas. You can track and control space usage for NTFS volumes among various users.

- NTFS has built-in dynamic compression, which compresses and decompresses files as you use them.

### Disk and File System Structures

To manage files on a disk and enable all applications to see a consistent interface to the file system no matter what type of storage hardware is being used, the operating system creates several structures on the disk. These structures are the same for any OS that supports the FAT file system, including Windows 9x, Windows Me, Windows NT, Windows 2000, and Windows XP. The following list shows all the structures and areas FAT uses to manage a disk, in roughly the same order in which they appear on the media:

- Master and extended partition boot records (sectors)
- Volume boot record
- Root directory
- File allocation tables
- Clusters (allocation units in the data area)
- Diagnostic read-and-write cylinder (not on all drives)

All these structures are detailed later in this section. A hard disk has all these disk-management structures, and a floppy disk has all but the master and extended partition boot records and diagnostic cylinder. The volume boot record through data area structures are repeated for each partition or volume on a drive. These structures are created on hard disk drives or other high-capacity media by the disk partitioning program included with all operating systems. You can’t use a disk partitioning program such as FDISK (MS-DOS/Windows 9x/Me) or DISKPART or Disk Management (Windows NT/2000/XP) on a floppy disk because floppy disks can’t be partitioned. Figure 24.1 is a simple diagram showing the relative locations of these FAT disk-management structures on an 8.4GB hard disk.

**Note**

Some removable cartridge drives, such as the SuperDisk (LS-120 and LS-240) and Iomega Zip drive, function like high-capacity floppy disk drives. They lack a master boot record (MBR) and diagnostic cylinder and can’t be partitioned like hard disk drives. Other higher-capacity removable drives, such as the legacy Iomega Jaz or Castlewood Orb, can be partitioned like a hard disk drive.
All PC hard drives using the FAT16 file system are similar.

**Figure 24.1** FAT16 file-management structures on a typical 8.4GB drive.

Each disk area has a purpose and function. If one of these special areas is damaged, serious consequences can result. Damage to one of these sensitive structures usually causes a domino effect, limiting access to other areas of the disk or causing further problems in using the disk. For example, the OS normally can’t access a drive at all if the MBR is corrupted. Therefore, you should understand these data structures well enough to be able to repair them when necessary. Rebuilding these special tables and areas of the disk is essential to the art of data recovery.

**Master Boot Record**

The first PC OS to support hard disks, DOS 2.0 (released on March 8, 1983), was also the first to introduce the capability to partition a drive. Partitioning is basically dividing the drive into multiple volumes. One concept easily misunderstood is that all drives that can be partitioned must be partitioned; that is, you have to partition the drive even if you are going to set it up with only one partition. Another name for a partition is a logical volume because the partition shows up as an additional drive letter or volume to the OS.

Although the primary use for partitioning today is to divide a single drive into multiple volumes for use by the same OS, originally it was intended to allow multiple different OSes, each with different file systems, to coexist on a single drive. This multi-OS capability still exists today; however, additional aftermarket utilities often are required to manage and boot from multiple OSes on a single machine.

**Tip**

If you want to dual-boot Windows 9x/Me with Windows 2000/XP without purchasing aftermarket boot managers, install Windows 9x or Me first and then install Windows 2000 or XP either on the unused space on the first hard disk or in a primary partition on an additional hard disk. Windows 2000 or XP will set up a boot manager for you.
To use a hard disk with different operating systems, you can create partitions to logically divide the disk. You can, for example, create one or more FAT or NTFS partitions for use with Windows and leave the rest of the disk storage area for use by another OS’s file system, such as Linux. Each of the FAT or NTFS partitions appear to an OS that supports it as a separate drive letter. For example, Windows 9x/Me ignores the unused or non-FAT partitions, whereas Windows 2000/XP sees both FAT and NTFS partitions but ignores others such as Linux and OS/2 HPFS.

Even though Windows NT, 2000, and XP have a command-line disk partitioning program called DISKPART, disk partitions are usually prepared with the GUI-based Disk Management tool (2000/XP) or Disk Administrator (NT).

For more information about creating and formatting partitions with any of these operating systems, see Chapter 14, “Physical Drive Installation and Configuration,” p. 797.

Information about each of the partitions on the disk is stored in a partition (or volume) boot record at the beginning of each partition. Additionally, a main table lists the partitions embedded in the master boot record.

The MBR, which is also sometimes called the master boot sector, is always located in the first physical sector of a disk (cylinder 0, head 0, sector 1) and consists of the following structures:

- Bootstrap code. The instructions used to locate and load the VBR from the active (bootable) partition.
- Master partition table. A table consisting of four 16-byte entries for up to four primary partitions, or three primary partitions and one extended partition. Each primary partition defines a logical drive, and an extended partition can be further partitioned into multiple logical drives. A given partition entry indicates which type of partition it is, whether it is bootable, where it is located physically on the disk, and how many sectors it occupies.
- Signature bytes. A 2-byte signature (55AAh) used by the motherboard ROM and other code to validate the sector.

**Primary and Extended FAT Partitions**

Most OSes are designed to support up to 24 volumes on a single hard disk drive (represented by the drive letters C:–Z:), but the partition table in the master boot record (MBR) can have a maximum of only four entries. This is handled by using a single primary partition, which is seen as the first logical drive (C:), and an extended partition, which is then further partitioned into additional logical drives (D:, E:, F:, and so on).

Note

Although Windows NT uses Disk Administrator and Windows 2000 and XP use Disk Management to create disk partitions instead of FDISK, the following discussion refers to FDISK for simplicity’s sake. A FAT partition up to 2GiB is the same with any of these operating systems.

An extended partition is listed in the master partition table the same as a primary partition, but it differs in that you can use its disk space to create multiple logical partitions, or volumes. You can create only one extended partition on a single drive, meaning that typically there will never be more than two entries in the master partition table, one primary and one extended.

The logical volumes you create in the extended partition appear as separate drive letters to the operating system, but they are not listed in the master partition table. Volumes in the extended partition are not bootable. You can create up to 23 volumes out of a single extended partition (assuming that you have already created a primary partition, which brings the total number of volumes to 24).

Each of the subpartitions in an extended partition includes an extended partition table located in the first sector of the subpartition. The first sector of the extended partition contains an extended partition table that points to the first subpartition and, optionally, another extended partition. The first sector of that extended partition has another extended partition table that can reference another volume as
well as an additional extended partition. This chain of references continues, linking all the volumes in
the extended partition to the master partition table. It is important to note that, if the entry for the
extended partition in the MBR is lost or damaged, the chain will be broken at the start and all vol-
umes contained within will be inaccessible—essentially meaning that they will dissapear.

Few people have any reason to create 24 partitions on a single disk drive, but the extended partition
can create a chain of linked partitions on the disk that makes it possible to exceed the four-entry limi-
tation of the master partition table.

Because the master boot record contains the first program loaded from disk that the system executes
when you boot a PC, it is frequently a target for creators of computer viruses. A virus that infects or
destroys the MBR can make it impossible for the BIOS to find the active partition, thus preventing the
operating system from loading. Because the MBR contains the first program executed by the system, a
virus stored there loads before any antivirus code can be loaded to detect it. To remove an MBR virus,
you must first boot the system from a clean, uninfected disk, such as a floppy, bootable CD/DVD, or
USB drive, and then run an antivirus program to test and possibly repair or restore the MBR.

Each partition on a disk contains a volume boot record starting in the first sector. With the FDISK or
DISKPART utilities, you can designate a primary partition as active (or bootable). The master boot
record bootstrap code causes the VBR from the active primary partition to receive control whenever
the system is started.

Although FAT12, FAT16, FAT32, or NTFS partitions are mainly used when running Windows, you can also
create additional disk partitions for Linux, Novell NetWare, OS/2's HPFS, AIX (Unix), XENIX, or other file
systems or operating systems, using disk utilities provided with the alternative OS or in some cases a third-
party disk partitioning tool such as PowerQuest's Partition Magic. A partition that is not recognized by a
particular operating system is simply ignored. If you install multiple operating systems on a single drive, a
boot manager program (which might be included with the operating systems or installed separately) can
be used to allow you to select which partition to make active each time you boot the system. As another
alternative, you could install different operating systems in different primary partitions and then use
FDISK, DISKPART, or some other partitioning program to change the one you want to boot as active.

Table 24.9 shows the format of the master boot record and its partition tables. The table lists the fields
in each of the master partition table's four entries, the location on the disk where each field begins
(the offset), and its length.

#### Signature Bytes

<table>
<thead>
<tr>
<th>Offset (Hex)</th>
<th>Offset (Dec)</th>
<th>Description</th>
<th>Length</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1FEh         | 510          | Signature   | 2 bytes| Boot sector signature; it should be 55AAh.    

**CHS** = Cylinder head sector  
**LBA** = Logical block address
The data in the partition table entries tells the system where each partition starts and ends on the drive, how big it is, whether it is bootable, and which type of file system is contained in the partition. The starting cylinder, head, and sector values are used only by systems running in CHS mode, which is standard for all drives of 8.4GB or less. CHS values do not work past 8.4GB and therefore cannot represent partitions on drives larger than that. Drives larger than 8.4GB can be fully addressed only in LBA mode. In that case, the starting cylinder, head, and sector values in the table are ignored, and only the Relative Sector and Total Sectors fields are used. The Relative Sector field indicates the precise LBA where the partition begins, and the Total Sectors field indicates the length, which is always contiguous. Thus, from those two values the system can know exactly where a partition is physically located on a disk.

Note

The processors on which the PC is based have a design characteristic that is important to know for anybody editing or interpreting boot sectors. Numbers larger than 1 byte are actually read backward! This is called little endian format (as in reading the number from the little end first) or reverse-byte ordering. People typically read numbers in big endian format, which means from left to right, from the big end first. However, because PC processors read in little endian format, most numeric values larger than 1 byte are stored so that the least significant byte appears first and the most significant byte appears last. For example, the value for the Relative Sector field in the MBR for the first partition is usually 63, which is 3Fh in hex, or 0000003Fh (4 bytes long) in standard big endian hexadecimal format. However, the same number stored in little endian format would appear as 3F000000h. As another example, if a partition had 23,567,292 total sectors (about 12GB), which is 01679BBCh in hexadecimal, the number would be stored in the MBR partition table Total Sectors field in reverse-byte/little endian format as BC9B6701h.

As an aside, the use of reverse-byte order numbers stems from the way processors evolved from 8-bit (1 byte) designs to 16-bit (2 byte), 32-bit (4 byte) designs and beyond. The way the internal registers are organized and implemented dictates how a processor deals with numbers. Many processors, such as the Motorola PowerPC chips used in Macintosh systems, read numbers in big endian format. PC processors, on the other hand, are all based on Intel designs dating back to the original Intel 8088 processor used in the first IBM PC. Of course, how a particular processor reads numbers doesn’t make any difference to those using a system. In the PC, the only people who have to deal with reverse-byte order or little endian numbers directly are machine or assembly language programmers—and those who want to edit or interpret raw boot sectors!

Each partition table entry contains a system indicator byte that identifies the type of partition and file system used in the partition referenced by that entry. Table 24.10 shows the standard values and meanings of the system indicator bytes, and Table 24.11 lists the nonstandard values.

These values can be useful for somebody trying to manually repair a partition table using a disk editor such as the Disk Edit program included with Norton Utilities (now part of Norton SystemWorks).

**Undocumented FDISK**

FDISK is a very powerful program. In DOS 5 and later versions, including Windows 9x/Me, it gained some additional capabilities (Windows NT uses Disk Administrator, whereas Windows 2000/XP use Disk Management or the DISKPART program to perform the functions of FDISK). Unfortunately, these capabilities were never documented in any of the Microsoft documentation for Windows or DOS. The most important undocumented parameter in FDISK is the `/MBR` (master boot record) parameter, which causes FDISK to rewrite the master boot record code area, leaving the partition table area intact.

The `/MBR` parameter is tailor-made for eliminating boot sector virus programs that infect the master boot record (located at cylinder 0, head 0, sector 1) of a hard disk. To use this feature, enter the following:

**FDISK /MBR**

FDISK then rewrites the boot record code, leaving the partition tables intact. This should not cause any problems on a normally functioning system, but just in case, I recommend backing up the partition table information to floppy disk before trying it. You can do this by using a third-party product such as Norton Utilities.

Be aware that using FDISK with the `/MBR` switch overwrites the partition tables if the two signature bytes at the end of the sector (55AAh) are damaged. This situation is highly unlikely, however. In fact, if these signature bytes were damaged, you would know—the system would not boot and would act as though there were no partitions at all. If you are unable to access your hard disk after booting from a clean floppy or removable-media drive, your system might be infected with a boot sector virus. You should scan for viruses with an up-to-date antivirus program and use it to guide repair.
Disk and File System Structures

Caution
Also note that FDISK /MBR should be used only on systems using the normal master boot record structure. If a disk-management program such as Disk Manager, Disk Wizard, EZDrive, MaxBlast, Data Lifeguard Tools, or similar is being used to allow your system to access the drive's full capacity, do not use FDISK /MBR because these programs use a modified MBR for disk access. Using FDISK /MBR will wipe out the changes they made to your drive and could make your data inaccessible.

The equivalent Windows NT/2000/XP Recovery Console feature to DOS/Windows 9x/Me's FDISK /MBR is called FIXMBR. The Recovery Console equivalent to FDISK is DISKPART. For details on the use of these commands, type HELP after loading the Recovery Console.

Volume Boot Records
The volume boot record is the first sector on any area of a drive addressed as a volume, including primary partitions or logical volumes inside an extended partition. On a floppy disk or removable cartridge (such as a Zip disk), for example, the volume boot record starts at the physical beginning of the disk because the disk is recognized as a volume without the need for partitioning. On a hard disk, the volume boot record is located as the first sectors within any disk area allocated as a primary partition, or as a logical drive (volume) inside an extended partition. Refer to Figure 24.1 for an idea of the physical relationship between this volume boot record and the other data structures on a disk. The volume boot record resembles the master boot record in that it contains the following elements:

- **Jump Instruction to Boot Code.** A 3-byte Intel x86 unconditional branch (or jump) instruction that jumps to the start of the operating system bootstrap code within the sector.
- **BIOS Parameter Block.** Contains specific information about the volume, such as its size, the number of disk sectors it uses, the size of its clusters, and the volume label name. Used by the file system driver to determine the type and status of the media. Varies according to the type of file system on the media.
- **Boot Code.** The instructions used to locate and load the initial operating system kernel or startup file, usually either IO.SYS or NTLDR.
- **Signature Bytes.** A two-byte signature (55AAh) used by the motherboard ROM and other code to validate the boot sector.

Either the motherboard ROM or the master boot record on a hard disk loads the volume boot record of the active partition on a disk. The program code in the volume boot record is given control of the system; it performs some tests and then attempts to load the first operating system file (in DOS/Windows 9x/Me the file is IO.SYS and in Windows NT/2000/XP the file is NTLDR). The volume boot record, similar to the master boot record, is transparent to the running system; it is outside the data area of the disk on which files are stored.

Note
Many of today's systems are capable of booting from drives other than standard floppy disk and hard disk drives. In these cases, the system BIOS must specifically support the boot drive. For example, some BIOS products enable you to select an ATAPI CD-ROM (or DVD) as a boot device, in addition to the floppy and hard disk drives. Many can also boot from drives connected to USB ports, adding even more flexibility to the system.

Other types of removable media, such as Zip cartridges and LS-120 disks, can also be made bootable. When the BIOS properly supports it, an LS-120 drive can replace the existing floppy disk drive as drive A:. Check the setup screens in your system BIOS to determine which types of drives can be used to start your system.

The VBR is typically created on a volume when the volume is high-level formatted. This can be done with the FORMAT command included with DOS and Windows, or you can also use Windows NT’s Disk
Administrator and Windows 2000/XP’s Disk Management programs to perform this task after partitioning the disk. All volumes have a VBR starting in the first sector of the volume.

The VBR contains both program code and data. The single data table in this sector is called the media parameter block or disk parameter block. The operating system needs the information this table contains to verify the capacity of the disk volume as well as the location of important structures, such as the FATs on FAT volumes or the Master File Table on NTFS volumes. The format of this data is very specific.

Although all VBRs contain boot code in addition to the BIOS parameter block (BPB) and other structures, only the boot code from the VBR in the bootable volume is executed. The others are read by the operating system during startup to determine the volume parameters.

The VBR on FAT12 and FAT16 volumes is 1 sector long and contains the jump instruction, the main BPB, bootstrap code, and signature bytes. Table 24.12 shows the format and layout of the FAT12/16 VBR.

The VBR on a FAT32 volume is 3 sectors long, although 32 sectors are reserved at the beginning of the volume for the default and backup VBRs. The default VBR is in sectors 0, 1, and 2, and the backup VBR is in sectors 6, 7, and 8. These are all created at the time the volume is formatted and do not change during normal use. The first sector contains a jump instruction, the BPB, initial bootstrap code, and signature bytes. The second sector is called the FSInfo (file system information) sector and contains signature bytes and information used to assist the file system software; the third sector contains only additional bootstrap code and signature bytes. Table 24.13 shows the format and layout of the first sector of the 3-sector long FAT32 VBR.

</tbody>
</table>

It is interesting to note that this third sector has no system-specific information in it, which means the contents are the same from system to system. Thus, if this sector (and its backup at LBA 8) were damaged on one system, you could obtain a copy of this sector from any other FAT32 volume and use it to restore the damaged sector.

The VBR on NTFS volumes is 7 sectors long, although 16 sectors are reserved at the beginning of the disk for the VBR. A backup of the 16 sector VBR area is reserved at the end of the volume, which contains a backup VBR. The first sector of the 7 is the BPB sector, and it contains a jump instruction, the BPB, and signature bytes. Sectors 2–7 contain only additional boot code, with no signature bytes or any other structures. Because the boot code is not system specific, all but the first VBR sector should be the same on any NTFS volume. Table 24.16 shows the format and layout of the first sector of the 7-sector-long NTFS VBR.

Root Directory

A directory is a simple database containing information about the files stored on a FAT partition. Each record in this database is 32 bytes long, with no delimiters or separating characters between the fields or records. A directory stores almost all the information that the operating system knows about a file, including the following:

- **Filename and extension.** The eight-character name and three-character extension of the file. The dot between the name and the extension is implied but not included in the entry.
Note
To see how Windows 9x/Me extends filenames to allow 255 characters within the 8.3 directory structure, see the section “VFAT and Long Filenames,” later in this chapter.

- **File attribute byte.** The byte containing the flags representing the standard DOS file attributes, using the format shown in Table 24.18.
- **Date/Time of last change.** The date and time that the file was created or last modified.
- **File size.** The size of the file, in bytes.
- **Link to start cluster.** The number of the cluster in the partition where the beginning of the file is stored. To learn more about clusters, see the section “Clusters (Allocation Units),” later in this chapter.

Other information exists that a directory does not contain about a file. This includes where the rest of its clusters in the partition are located and whether the file is contiguous or fragmented. This information is contained in the FAT.

Two basic types of directories exist: the root directory (also called the root folder) and subdirectories (also called folders). Any given volume can have only one root directory. The root directory is always stored on a disk in a fixed location immediately following the two copies of the FAT. Root directories vary in size because of the different types and capacities of disks, but the root directory of a given disk is fixed. Using the **FORMAT** command creates a root directory that has a fixed length and can’t be extended to hold more entries. The root directory entry limits are shown in Table 24.17. Subdirectories are stored as files in the data area of the disk and can grow in size dynamically; therefore, they have no fixed length limits.

<table>

<td>512</td>
</tr>
</tbody>
</table>

Note
Two advantages of the FAT32 file system are that the root directory can be located anywhere on the disk and it can have an unlimited number of entries. FAT32 is discussed in more detail later in this chapter.

Every directory, whether it is the root directory or a subdirectory, is organized in the same way. Entries in the directory database store important information about individual files and how files are named on the disk. The directory information is linked to the FAT by the starting cluster entry. In fact, if no file on a disk were longer than one single cluster, the FAT would be unnecessary. The directory stores all the information needed by DOS to manage the file, with the exception of the list of clusters the file occupies other than the first one. The FAT stores the remaining information about the other clusters the file occupies.

To trace a file on a disk, use a disk editor, such as the Disk Edit program that comes with the Norton Utilities. Start by looking up the directory entry to get the information about the starting cluster of the file and its size. Then, using the appropriate editor commands, go to the FAT where you can follow the chain of clusters the file occupies until you reach the end of the file. By using the directory and FAT in this manner, you can visit all the clusters on the disk that are occupied by the file. This type of technique can be useful when these entries are corrupted and when you are trying to find missing parts of a file.
FAT directory entries are 32 bytes long and are in the format shown in Table 24.18, which shows the location (or offset) of each field within the entry (in both hexadecimal and decimal form) and the length of each field.

**Table 24.18  FAT Directory Format**

<table>
<thead>
<tr>
<th>Offset (Hex)</th>
<th>Offset (Dec)</th>
<th>Field Length</th>
<th>Description</th>

<td>28</td>
<td>1 dword</td>
<td>Size in bytes</td>
</tr>
</tbody>
</table>

Filenames and extensions are left justified and padded with spaces, (which are represented as ASCII 32h bytes). In other words, if your filename is “AL”, it is really stored as “AL------”, where the hyphens are spaces. The first byte of the filename indicates the file status for that directory entry, shown in Table 24.19.

**Table 24.19  Directory Entry Status Byte (First Byte)**

<table>
<thead>
<tr>
<th>Hex</th>
<th>File Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>00h</td>
<td>Entry never used; entries past this point not searched.</td>

<tr>
<td>05h</td>
<td>Indicates that the first character of the filename is actually E5h.</td>
</tr>
<tr>
<td>E5h</td>
<td>σ (lowercase sigma). Indicates that the file has been erased.</td>
</tr>
<tr>
<td>2Eh</td>
<td>. (period). Indicates that this entry is a directory. If the second byte is also 2Eh, the cluster field contains the cluster number of the parent directory (0000h, if the parent is the root).</td>
</tr>
</tbody>
</table>

A word is 2 bytes read in reverse order, and a dword is two words read in reverse order.

Table 24.20 describes the FAT directory file attribute byte. Attributes are 1-bit flags that control specific properties of a file, such as whether it is hidden or designated as read-only. Each flag is individually activated (1) or deactivated (0) by changing the bit value. The combination of the eight bit values can be expressed as a single hexadecimal byte value; for example, 07h translates to 00000011, and the 1 bits in positions 3, 2, and 1 indicate the file is system, hidden, and read-only.

**Table 24.20  FAT Directory File Attribute Byte**

</tr>
<tr>
<td>0 0 1 0 0 1 1 1</td>
<td>27h</td>
<td>Read-only, hidden, system, archive</td>
</tr>
</tbody>
</table>

**Note**
The DOS/Windows command-line `ATTRIB` command can be used to change file attributes. In the Windows GUI, you can use the properties sheet for a file or folder to change the attributes. The archive bit changes automatically when a file is backed up or changed.

**File Allocation Tables**
The file allocation table is a list of numerical entries describing how each cluster in the partition is allocated. The data area of the partition has a single entry in the table for each of its clusters. Sectors in the non-data area of the partition are outside the range of the disk controlled by the FAT. Thus, the sectors that comprise the boot records, FATs, and root directory are outside the range of sectors controlled by the FAT.

See "The Data Area," p. 1327.

The FAT does not manage every data sector specifically, but rather allocates space in groups of sectors called clusters or allocation units. A cluster is a unit of storage consisting of one or more sectors. The FDISK program determines the size of a cluster during the creation of the partition, based on the partition’s size and the file system selected (FAT16 or FAT32). The smallest space a file can occupy in a partition is one cluster; all files use space in integer (whole) cluster units. If a file is one byte larger than one cluster, two whole clusters are used.

You can think of the FAT as a type of spreadsheet that tracks the allocation of the disk’s clusters. Each cell in the spreadsheet corresponds to a single cluster on the disk. The number stored in that cell is a code indicating whether a file uses the cluster and, if so, where the next cluster of the file is located. Thus, to determine which clusters a particular file is using, you would start by looking at the first FAT reference in the file's directory entry. When you look up the referenced cluster in the FAT, the table contains a reference to the file’s next cluster. Each FAT reference, therefore, points to the next cluster in what is called a FAT chain until you reach the cluster containing the end of the file. Numbers stored in the FAT are hexadecimal numbers that are either 12 or 16 bits long. The 16-bit FAT numbers are easy to follow in a disk sector editor because they take an even 2 bytes of space. The 12-bit numbers are 1 1/2 bytes long, which presents a problem because most disk sector editors show data in byte units. To edit a 12-bit FAT, you must do some hex/binary math to convert the displayed byte units to FAT numbers. Fortunately (unless you are using the DOS DEBUG program), most of the available tools and utility programs have a FAT-editing mode that automatically converts the numbers for you. Most of them also show the FAT numbers in decimal form, which most people find easier to handle. Table 24.21 shows the relationship between the directory and FAT for a given file (assuming the file is not fragmented).
Table 24.21  Directory and FAT Relationship (File Not Fragmented)

<td>Cluster available</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>65526</td>
<td>0</td>
<td>Last cluster available</td>
</tr>
</tbody>
</table>

In this example, the directory entry states that the file starts in cluster number 1000. In the FAT, that cluster has a nonzero value, which indicates it is in use; the specific value indicates where the file using it would continue. In this case, the entry for cluster 1000 is 1001, which means the file continues in cluster 1001. The entry in 1001 points to 1002, and from 1002 the entry points to 1003. The entry for 1003 is FFFFh, which is an indication that the cluster is in use but that the file ends here and uses no additional clusters.

The use of the FAT becomes clearer when you see that files can be fragmented. Let’s say that before the USCONST.TXT file was written, another file already occupied clusters 1002 and 1003. If USCONST.TXT was written starting at 1000, it would not have been capable of being completely written before running into the other file. As such, the operating system would skip over the used clusters and continue the file in the next available cluster. The end result is shown in Table 24.22.

In this example, the PLEDGE.TXT file that was previously written interrupted USCONST.TXT, so those clusters are skipped over, and the pointers in the FAT reflect that. Note that the defrag programs included with DOS and Windows take an example like this and move the files so they are contiguous, one after the other, and update the FAT to indicate the change in cluster use.

The first two entries in the FAT are reserved and contain information about the table itself. All remaining entries correspond to specific clusters on the disk. Most FAT entries consist of a reference to another cluster containing the next part of a particular file. However, some FAT entries contain hexadecimal values with special meanings, as follows:

- **0000h**: Indicates that the cluster is not in use by a file
- **FFFFh**: Indicates that at least one sector in the cluster is damaged and that it should not be used to store data
- **FFF8h–FFFFh**: Indicates that the cluster contains the end of a file and that no reference to another cluster is necessary

The FDISK program generally determines whether a 12-bit, 16-bit, or 32-bit FAT is placed on a disk, even though the FAT isn’t written until you perform a high-level format (using the FORMAT utility). On today’s systems, usually only floppy disks use 12-bit FATs, but FDISK also creates a 12-bit FAT if you create a hard disk volume that is smaller than 16MiB. On hard disk volumes of more than 16MiB, FDISK creates a 16-bit FAT. On drives larger than 512MiB, the FDISK program included in Windows 95 OSR2, and Windows 98/Me enables you to create 32-bit FATs when you answer Yes to the question Enable Large Disk Support? when you start FDISK. You can also select FAT32 when you prepare a drive with the Windows 2000 or Windows XP Disk Management program (Windows NT doesn’t support FAT32).

FAT volumes normally have two copies of the FAT. Each one occupies contiguous sectors on the disk, and the second FAT copy immediately follows the first. Unfortunately, the operating system uses the second FAT copy only if sectors in the first FAT copy become unreadable. If the first FAT copy is corrupted, which is a much more common problem, the operating system does not use the second FAT copy. Even the CHKDSK command does not check or verify the second FAT copy. Moreover, whenever the OS updates the first FAT, it automatically copies large portions of the first FAT to the second FAT. If the first copy was corrupted and subsequently updated by the OS, a large portion of the first FAT is copied over to the second FAT copy, damaging it in the process. After the update, the second copy is usually a mirror image of the first one, complete with any corruption. Two FATs rarely stay out of sync for very long. When they are out of sync and the OS writes to the disk, it updates the first FAT and overwrites the second FAT with the first. This is why disk repair and recovery utilities warn you to stop working as soon as you detect a FAT problem. Programs such as Norton Disk Doctor (included with the Norton Utilities which are a part of Norton SystemWorks) use the second copy of the FAT as a reference to repair the first one, but if the OS has already updated the second FAT, repair might be impossible.
Clusters (Allocation Units)

A cluster is often called an allocation unit. Allocation unit is appropriate because a single cluster is the smallest unit of the disk that the operating system can handle when it writes or reads a file. A cluster is equal to one or more 512-byte sectors, in a power of 2. Although a cluster can be a single disk sector, it is usually more than one. Having more than one sector per cluster reduces the size and processing overhead of the FAT and enables the operating system to run faster because it has fewer individual units to manage. The trade-off is in wasted disk space. Because operating systems manage space only in full-cluster units, every file consumes space on the disk in increments of one cluster.

Table 24.23 shows the default cluster (or allocation unit) sizes for the various floppy disk formats used over the years.

<table>

<td>Extra</td>
</tr>
</tbody>
</table>

It seems strange that the high-density disks, which have many more individual sectors than low-density disks, sometimes have smaller cluster sizes. The larger the FAT, the more entries the operating system must manage and the slower it seems to function. This sluggishness is due to the excessive overhead required to manage all the individual clusters; the more clusters to be managed, the slower things become. The trade-off is in the minimum cluster size. High-density floppy disk drives are faster than their low-density counterparts, so perhaps IBM and Microsoft determined that the decrease in cluster size balances the drive’s faster operation and offsets the use of a larger FAT.

Because the operating system can allocate only whole clusters, inevitably a certain amount of wasted storage space results. File sizes rarely fall on cluster boundaries, so the last cluster allocated to a particular file is rarely filled completely. The extra space left over between the actual end of the file and the end of the cluster is called slack. A partition with large clusters has more slack space, whereas smaller clusters generate less slack.

For hard disks, the cluster size varies greatly among partition sizes and file systems. Table 24.24 shows the cluster sizes FDISK selects for a particular volume size when FAT16 is the file system used.

<table>

</tr>
</tbody>
</table>

1. Volumes smaller than 16MiB default to FAT12; however, FAT32 can be forced in some cases by altering the format parameters.
2. Volumes larger than 2GiB are supported only by Windows NT/2000/XP and are not recommended.

MB = Megabyte = 1,000,000 bytes
GB = Gigabyte = 1,000MB = 1,000,000,000 bytes
TB = Terabyte = 1,000GB = 1,000,000,000,000 bytes
KiB = Kibibytes = 1,024 bytes
MiB = Mebibyte = 1,024KiB = 1,048,576 bytes
GiB = Gibibyte = 1,024MiB = 1,073,741,824 bytes
The effect of larger cluster sizes on disk utilization can be substantial. A 2GiB partition containing about 5,000 files, with average slack of one-half of the last 32KiB cluster used for each file, wastes more than 78MB (5000 × (0.5 × 32)KiB) of file space. When files under 32KiB in size are stored on a drive with a 32KiB allocation unit, waste (slack) factors can approach 40% of the drive’s capacity.

16-bit cluster numbers range from 0000h to FFFFh, which is 0–65,535 in decimal. This theoretically allows 65,536 total clusters, but 11 of the cluster numbers are reserved and cannot be assigned to actual clusters on a disk. Cluster numbers start at 2 (0 and 1 are reserved), number FFF7h is reserved to indicate a bad cluster, and numbers FFF8h–FFFFh indicate an end-of-chain in the FAT, leaving 65,525 clusters (65,536 – 11). Microsoft subtracts 1 from this to eliminate boundary problems, allowing up to 65,524 clusters maximum in a FAT16 volume.

FAT16 volumes include 1 sector for the boot record and BPB, two copies of the FAT (default and backup) up to 256 sectors long each, 32 sectors for the root directory, and a data area with 4,085–65,524 clusters. Because each FAT16 cluster can be up to 64 sectors (32KiB) in size, FAT16 volumes are limited to a maximum size of 4,194,081 sectors (1 sector for the boot record + 256 sectors per FAT × 2 FATs + 32 sectors for the Root Directory + 65,524 clusters × 64 sectors per cluster), which equals a maximum capacity of 2.15GB or 2GiB.

**Note**

Windows NT/2000/XP support the use of 64KiB clusters on FAT16 partitions, enabling you to create partitions up to 4GiB in size. However, the huge amount of slack that generally results from clusters this large makes this practice undesirable. Also note that no other operating systems with FAT16 support are capable of accessing a FAT16 partition larger than 2GiB.

**The Data Area**

The data area of a partition is the place where the actual files are stored. It is located following the boot record, file allocation tables, and root directory. This is the area of the disk that is divided into clusters and managed by the FAT and root directory.

**Diagnostic Read-and-Write Cylinder**

The FDISK partitioning program always reserves the last cylinder of a hard disk for use as a special diagnostic read-and-write test cylinder. Because this cylinder is reserved, FDISK always reports fewer total cylinders than the drive manufacturer states are available. Operating systems do not use this cylinder for any normal purpose because it lies outside the partitioned area of the disk.

Cu See “Disk Formatting,” p. 609.

On systems with IDE or SCSI disk interfaces, the drive and controller also might allocate an additional area past the logical end of the drive for a bad-track table and spare sectors. This situation can account for additional discrepancies between the FDISK and the drive manufacturer’s reported sizes.

The diagnostics area enables software such as a manufacturer-supplied diagnostics disk to perform read-and-write tests on a hard disk without corrupting any user data. Many of these programs also swap spare cylinders for damaged cylinders if damaged cylinders are detected during testing.

**VFAT and Long Filenames**

The original Windows 95 release uses what is essentially the same FAT file system as DOS, except for a few important enhancements. Like much of the rest of Windows 95, the operating system support for the FAT file system was rewritten using 32-bit code and called *VFAT (virtual file allocation table)*. VFAT works in combination with the 32-bit protected mode VCACHE (which replaces the 16-bit real mode SMARTDrive cache used in DOS and Windows 3.1) to provide better file system performance. However, the most obvious improvement in VFAT is its support for long filenames. DOS and Windows 3.1 had been encumbered by the standard 8.3 filenaming convention for many years, and
adding long filename support was a high priority in Windows 95—particularly in light of the fact that Macintosh and OS/2 users had long enjoyed this capability.

The problem for the Windows 95 designers, as is often the case in the PC industry, was backward compatibility. It is no great feat to make long filenames possible when you are designing a new file system from scratch, as Microsoft did years before with Windows NT’s NTFS. However, the Windows 95 developers wanted to add long filenames to the existing FAT file system and still make it possible to store those names on existing DOS volumes and for previous versions of DOS and Windows to access the files.

VFAT provides the capability to assign file and directory names that are up to 255 characters in length (including the length of the path). The three-character extension is maintained because, like previous Windows versions, Windows 9x relies on the extensions to associate file types with specific applications. VFAT’s long filenames can also include spaces, as well as the following characters, which standard DOS 8.3 names can’t: +, ; = [ ].

The first problem when implementing the long filenames was how to make them usable to previous versions of DOS and 16-bit Windows applications that support only 8.3 names. The resolution to this problem was to give each file two names: a long filename and an alias that uses the traditional 8.3 naming convention. When you create a file with a long filename in Windows 9x/Me, VFAT uses the following process to create an equivalent 8.3 alias name:

1. The first three characters after the last dot in the long filename become the extension of the alias.
2. The first six characters of the long filename (excluding spaces, which are ignored) are converted into uppercase and become the first six characters of the alias filename. If any of these six characters are illegal under the standard 8.3 naming rules (that is, +, ; = [ ]), VFAT converts those characters into underscores.
3. VFAT adds the two characters ~1 as the seventh and eighth characters of the alias filename, unless this will result in a name conflict, in which case it uses ~2, ~3, and so on, as necessary.

**Aliasing in Windows NT/2000/XP**

Note that Windows NT/2000/XP creates aliases differently than Windows 9x/Me (as shown later).

NT/2000/XP begins by taking the first six legal characters in the LFN and following them with a tilde and number. If the first six characters are unique, a number 1 follows the tilde.

If the first six characters aren’t unique, a number 2 is added. NT/2000/XP uses the first three legal characters following the last period in the LFN for a file extension.

At the fifth iteration of this process, NT/2000/XP takes only the first two legal characters, performs a hash on the filename to produce four hexadecimal characters, places the four hex characters after the first two legal characters, and appends a ~5. The ~5 remains for all subsequent aliases; only the hex numbers change.

**Tip**

You can modify the behavior of the VFAT filename truncation mechanism to make it use the first eight characters of the long filename instead of the first six characters plus ~1. To do this, you must add a new binary value to the HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\FileSystem Registry key called NameNumericTail, with a value of 0. Changing the value to 1 returns the truncation process to its original state.

Although this Registry change creates “friendly” alias names, it causes many programs working with alias names to fail and is not recommended.
VFAT and Long Filenames

VFAT stores this alias filename in the standard name field of the file's directory entry. Any version of DOS or 16-bit Windows can therefore access the file using the alias name. The big problem that still remains, however, is where to store the long filenames. Clearly, storing a 255-character filename in a 32-byte directory entry is impossible (because each character requires 1 byte). However, modifying the structure of the directory entry would make the files unusable by previous DOS versions.

The developers of VFAT resolved this problem by using additional directory entries to store the long filenames. Each of the directory entries is still 32 bytes long, so up to 8 might be required for each long name, depending on its length. To ensure that these additional directory entries are not misinterpreted by earlier DOS versions, VFAT flags them with a combination of attributes that is not possible for a normal file: read-only, hidden, system, and volume label. These attributes cause DOS to ignore the long filename entries, while preventing them from being mistakenly overwritten.

Caution

When using long filenames on a standard FAT12 or FAT16 partition, you should avoid storing them in the root directory. Files with long names that take up multiple directory entries can more easily use up the limited number of entries allotted to the root directory than files with 8.3 names. On FAT32 drives, this is not a problem because the root directory has an unlimited number of entries.

In an experiment, I created a small (1KiB) text file on a floppy disk and gave it a 135-character long filename using Windows 98. I copied the file and pasted it repeatedly into the root directory of a floppy disk using Windows Explorer. Before I could make 20 copies of the file, the system displayed a File copying error. The disk could not accept any more files because the extremely long filename had used up all the root directory entries.

This solution for implementing backward-compatible long filenames in Windows 9x is ingenious, but it is not without its problems. Most of these problems stem from the use of applications that can access only the 8.3 alias names assigned to files. In some cases, if you open a file with a long name using one of these programs and save it again, the connection to the additional directory entries containing the long name is severed and the long name is lost.

This is especially true for older versions of disk utilities, such as Norton Disk Doctor for MS-DOS, that are not designed to support VFAT. Most older applications ignore the additional directory entries because of the combination of attributes assigned to them, but disk repair utilities usually are designed to detect and “correct” discrepancies of this type. The result is that running an old version of Norton Disk Doctor on a partition with long filenames results in the loss of all the long names. In the same way, backup utilities not designed for use with VFAT can strip off the long filenames from a partition.

Note

When using VFAT's long filename capabilities, you definitely should use disk and backup utilities that are intended to support VFAT. Windows 9x includes VFAT-compatible disk repair, defragmentation, and backup programs. If, however, you are for some reason inclined to use an older program that does not support VFAT, Windows 9x includes a clumsy, but effective, solution.

A program is included on the Windows 9x CD-ROM called LFNBLK.EXE. It doesn't install with the operating system, but you can use it to strip the long filenames from a VFAT volume and store them in a text file called LFNBLK.DAT. You can then work with the files on the volume as though they were standard 8.3 FAT files. Afterward, you can use LFNBLK.EXE to restore the long filenames to their original places (assuming the file and directory structure has not changed). This is not a convenient solution, nor is it recommended for use in anything but extraordinary circumstances, but the capability is there if needed. Some backup programs designed for disaster recovery (which enable you to reconstruct the contents of the hard drive without reloading Windows first) have used this feature to enable restoration of a Windows drive with long filenames from a DOS prompt (where only 8.3 alias names usually are supported).
Another problem with VFAT’s long filenames involves the process by which the file system creates the 8.3 alias names. VFAT creates a new alias every time you create or copy a file into a new directory; therefore, the alias can change. For example, you might have a file called Expenses-January98.doc stored in a directory with the alias EXPENS~1.DOC. If you use Windows 9x Explorer to copy this file to a directory that already contains a file called Expenses-December97.doc, you are likely to find that this existing file is already using the alias EXPENS~1.DOC. In this case, VFAT assigns EXPENS~2.DOC as the alias of the newly copied file, with no warning to the user. This is not a problem for applications that support VFAT because the long filenames are unchanged, but a user running an older application might open the EXPENS~1.DOC file expecting to find the list of January 1998 expenses and see the December 1997 expenses list instead.

**FAT32**

When the FAT file system was being developed, 2GB hard disk drives were a fantasy and no one expected the partition size limitation imposed by the combination of 16-bit FAT entries and 32KiB cluster sizes to be a problem. Today, however, even low-end PCs come equipped with hard drives holding at least 20GB, and 80GB and larger drives are common. When you use the standard FAT16 file system with these larger drives, you must create several partitions, each no larger than approximately 2GiB. To many users, having multiple drive letters representing a single disk is confusing, making organizing and locating files difficult.

To address this problem, Microsoft released an enhanced version of the FAT file system, called FAT32. FAT32 works just like the standard FAT; the only difference is that it uses numbers with more digits, so it can manage more clusters on a disk. Unlike VFAT, which is a Windows 9x innovation that uses existing file system structures, FAT32 is an enhancement of the FAT file system itself. In other words, whereas VFAT is implemented as part of the Windows 9x Virtual Machine Manager (Vmm.vxd), FAT32 is implemented by the FDISK program before the Windows GUI is even loaded. FAT32 was first included in the Windows 95 OEM Service Release 2 (OSR2, also known as Windows 95B) and is also part of Windows 98/Me, Windows 2000, and Windows XP operating systems.

**Note**

Because the FDISK utility can implement the FAT32 file system when you partition the drive, you can’t use FAT32 on a floppy disk or any removable cartridge that does not use a partition table. However, any medium you can partition with FDISK can use FAT32.

The most obvious improvement in FAT32 is that by using 32-bit values for FAT entries instead of 16-bit ones, the maximum number of clusters allowed in a single partition jumps from 65,536 (2¹⁶) to 268,435,456. This value is equivalent to 2²⁸, not 2³², because 4 bits out of the 32 are reserved for other uses. FAT32 also uses 32-bit values for the low-level operating system calls used to retrieve a specific disk sector.

These expanded values blow the top off the 2GiB limit on partition sizes. Because each FAT32 cluster is up to 64 sectors (32KiB) in size, FAT32 disks or partitions can theoretically be up to 17,184,062,816 sectors (32 sectors for the boot record + 2,097,152 sectors per FAT × 2 FATs + 268,435,445 clusters × 64 sectors per cluster), which equals a capacity of 8.8TB or 8TiB. Note that this capacity is theoretical because the 32-bit sector numbering scheme used in the partition tables located in the MBR limits a disk to no more than 4,294,967,295 (2³²–1) sectors, which is 2.2TB or 2TiB. Therefore, even though FAT32 can in theory handle a volume of up to 8.8TB, the reality is that it’s currently limited by the partition table format of the MBR to only 2.2TB. At the current rate of hard disk capacity growth, single drives of that size will come into existence between the years 2009 and 2011. Of course, by that time the MBR limitation should be addressed.

Individual files can be up to 1 byte less than 4GiB in size and are limited by the size field in the directory entry, which is 4 bytes long. Because the clusters are numbered using 32-bit values instead of 16-bit ones, the format of the directory entries on a FAT32 partition must be changed slightly. The 2-byte Link to Start Cluster field is increased to 4 bytes, using 2 of the 10 bytes (bytes 12–21) in the directory entry that were reserved for future use.
Windows 2000 and Windows XP are intentionally limited to format FAT32 volumes of up to only 32GiB in size but can read larger FAT32 partitions. The limit is there not for any technical reason, but because Microsoft wants to encourage people to use NTFS instead of FAT32.

Another important difference in FAT32 partitions is the nature of the root directory. In a FAT32 partition, the root directory does not occupy a fixed position on the disk as in a FAT16 partition. Instead, it can be located anywhere in the partition and expand to any size. This eliminates the preset limit on root directory entries and provides the infrastructure necessary to make FAT32 partitions dynamically resizable. Unfortunately, Microsoft never implemented that feature in Windows, but third-party products such as PowerQuest's PartitionMagic can take advantage of this capability.

The main drawback of FAT32 is that it is not compatible with previous versions of DOS and Windows 95. You can't boot to a previous version of DOS or (pre-OSR2) Windows 95 from a FAT32 drive, nor can a system started with an old DOS or Windows 95 boot disk see FAT32 partitions. Most recent distributions of Linux now support FAT32, and even the Mac OS 8.1 and later can read and write FAT32 volumes. For all but the oldest of equipment, FAT32 is the most universally understandable format that supports larger volumes.

**FAT32 Cluster Sizes**

Because FAT32 partitions can have so many more clusters than FAT16 partitions, the clusters themselves can be smaller. Using smaller clusters reduces the wasted disk space caused by slack. For example, the same 2GiB partition with 5,000 files on it mentioned earlier would use 4KiB clusters with FAT32 instead of 32KiB clusters with FAT16. Assuming the same amount of slack for each file, the smaller cluster size reduces the average amount of wasted space on that partition from more than 78MB to less than 10MB.

To compare FAT16 and FAT32, you can look at how a file would be stored on each. For FAT16, I’ll use the same example as before. With FAT16 the cluster numbers are stored as 16-bit entries, from 0000h to FFFFh. The largest value possible is FFFFh, which corresponds to 65,535 in decimal, but several numbers at the beginning and end are reserved for special use. The actual cluster numbers allowed in a FAT16 system range from 0002h to FFF6h, which is 2–65,526 in decimal. All files must be stored in cluster numbers within that range. That leaves only 65,524 valid clusters to use for storing files (cluster numbers below 2 and above 65,526 are reserved), meaning a partition must be broken up into that many clusters or less. A typical file entry under FAT16 might look like Table 24.25.

### Table 24.25  FAT16 File Entries

<table>

<td>Last cluster available</td>
</tr>
</tbody>
</table>
With FAT32, the cluster numbers range from 00000000h to FFFFFFFFh, which is 0–4,294,967,295 in decimal. Again, some values at the low and high ends are reserved, and only values between 00000002h and FFFFFFF6h are valid, which means values 2–4,294,967,286 are valid. This leaves 4,294,967,284 valid entries, so the drive must be split into that many clusters or less. Because a drive can be split into so many more clusters, the clusters can be smaller, which conserves disk space. The same file as shown earlier could be stored on a FAT32 system as illustrated in Table 24.26.

</tr>
</tbody>
</table>

Because the FAT32 system enables many more clusters to be allocated, the cluster size is usually smaller. So, although files overall use more individual clusters, less wasted space results because the last cluster is, on average, only half filled.

**Note**

Table 24.27 lists the cluster sizes for various FAT32 partition sizes.

</tr>
</tbody>
</table>

1. FAT32 cannot be used on volumes 66,600 sectors (32.52MiB) or less.
2. Volumes smaller than 512MiB will default to FAT16, although FAT32 can be forced by altering the format parameters.
3. Windows 2000 and XP format FAT32 volumes only up to 32GiB; however, they do support existing FAT32 volumes up to 2TiB.

Some additional limitations exist on FAT32 volumes. Volumes less than 512MiB default to FAT16, but FAT32 partitions as small as 32.52MiB can be forced using the proper utilities or commands. Anything smaller than that, however, must be either FAT16 or FAT12.

Windows 2000/XP or later will not format a volume larger than 32GiB using FAT32. If you attempt to format a FAT32 partition larger than 32GiB under Windows 2000/XP or later, the format operation will fail near the end of the process and you might receive the following error message: Logical Disk Manager: Volume size too big. If you want to use a larger FAT32 partition under Windows 2000/XP or later, you can format the partition using Windows 9x/Me because Windows 2000/XP or later will mount and support larger FAT32 partitions without any problems. The only limitation with FAT32 partitions under Windows 2000/XP or later is in the formatting process. Finally, remember that DOS 6.22 and earlier, Windows 95a, and Windows NT (through 4.0) do not recognize FAT32 partitions and are incapable of booting from a FAT32 volume.

Using smaller clusters results in many more clusters and more entries in the FAT. A 2GiB partition using FAT32 requires up to 524,288 FAT entries, whereas the same drive needs only 65,536 entries using FAT16. Thus, the size of one copy of the FAT16 table is 128KiB (65,536 entries × 16 bits = 1,048,576 bits/8 = 131,072 bytes), whereas the FAT32 table is 2MiB in size.

The size of the FAT has a definite impact on the performance of the file system. Windows 9x/Me uses VCACHE to keep the FAT in memory at all times to improve file system performance. The use of 4KiB clusters for drives up to 8GiB in size is, therefore, a reasonable compromise for the average PC's memory capacity. If the file system were to use clusters equal to one disk sector (1 sector = 512KiB) in an attempt to minimize slack as much as possible, the FAT table for a 2GiB drive would contain 4,194,304 entries and be 16MiB in size.

This would monopolize a substantial portion of the memory in the average system, probably resulting in noticeably degraded performance. Although at first it might seem as though even a 2MiB FAT is quite large when compared to 128KiB, keep in mind that hard disk drives are a great deal faster now than they were when the FAT file system was originally designed. In practice, FAT32 typically results in a minor (less than 5%) improvement in file system performance. However, systems that perform a great many sequential disk writes might see an equally minor degradation in performance.

**FAT Mirroring**

FAT32 also takes greater advantage of the two copies of the FAT stored on a disk partition. On a FAT16 partition, the first copy of the FAT is always the primary copy and replicates its data to the secondary FAT, sometimes corrupting it in the process. On a FAT32 partition, when the system detects a problem with the primary copy of the FAT, it can switch to the other copy, which then becomes the primary.
Chapter 24

File Systems and Data Recovery

The system can also disable the FAT mirroring process to prevent the viable FAT from being corrupted by the other copy. This provides a greater degree of fault tolerance to FAT32 partitions, often enabling you to repair a damaged FAT without an immediate system interruption or a loss of table data.

Creating FAT32 Partitions

Despite the substantial changes FAT32 provides, the new file system does have a large effect on the procedures you use to create and manage partitions. You create new FAT32 partitions in Windows 9x/Me using the FDISK utility from the command prompt, just as you would create FAT16 partitions. When you launch FDISK, the program examines your hard disk drives and, if they have a capacity greater than 512MiB, presents the following message:

Your computer has a disk larger than 512MB. This version of Windows includes improved support for large disks, resulting in more efficient use of disk space on large drives, and allowing disks over 2GB to be formatted as a single drive.

IMPORTANT: If you enable large disk support and create any new drives on this disk, you will not be able to access the new drive(s) using other operating systems, including some versions of Windows 95 and Windows NT, as well as earlier versions of Windows and MS-DOS. In addition, disk utilities that were not designed explicitly for the FAT32 file system will not be able to work with this disk. If you need to access this disk with other operating systems or older disk utilities, do not enable large drive support.

Do you wish to enable large disk support (Y/N)...........? [N]

If you answer Yes to this question, any partitions you create that are larger than 512MiB will be FAT32 partitions. If you want to create partitions larger than 2GiB, you must use FAT32. Otherwise, you can choose which file system you prefer. All the screens following this one are the same as those in previous versions of FDISK.

Normally, the FDISK utility determines the cluster size used when you format the partition, based on the partition's size and the file system used. However, you can override FDISK using an undocumented switch for the FORMAT utility. If you use the command

`FORMAT /Z:n`

where \( n \) multiplied by 512 equals the desired cluster size in bytes, you can create a partition that uses cluster sizes that are larger or smaller than the defaults for the file system.

**Caution**

The /Z switch does not override the 65,534-cluster limit on FAT16 partitions, so it is recommended that you use it only with FAT32. In addition, you should not use this switch on a production system without extensive testing first. Modifying the cluster size can increase or decrease the amount of slack on the partition, but it also can have a pronounced effect on the performance of the drive. Some disk utilities might not work with nonstandard cluster sizes.

Converting FAT16 to FAT32

If you want to convert an existing FAT16 partition to FAT32, Windows 98 and Me later include a FAT32 Conversion Wizard that enables you to migrate existing partitions in place.

The wizard gathers the information needed to perform the conversion, informs you of the consequences of implementing FAT32, and attempts to prevent data loss and other problems. After you have selected the drive you want to convert, the wizard performs a scan for applications (such as disk utilities) that might not function properly on the converted partition. The wizard gives you the opportunity to remove these and warns you to back up the data on the partition before proceeding.
with the conversion. Even if you don’t use the Microsoft Backup utility the wizard offers, backing up your data is a strongly recommended precaution.

Because the conversion must deal with the existing partition data in addition to creating new volume boot record information, FATs, and clusters, the process can take far longer than partitioning and formatting an empty drive. Depending on the amount of data involved and the new cluster size, the conversion can take several hours to complete.

After you convert a FAT16 partition to FAT32, you can’t convert it back with Windows tools, except by destroying the partition and using FDISK to create a new one. Aftermarket partitioning utilities are available that can convert FAT32 back to FAT16 if you want. You should take precautions before beginning the conversion process, such as connecting the system to a UPS. A power failure during the conversion could result in a loss of data.

Third-Party Partitioning Utilities

Windows includes only basic tools for creating FAT32 partitions, but programs such as Partition Commander from VCOM (www.v-com.com) and PartitionMagic from PowerQuest (www.powerquest.com) provide many other partition manipulation features. These programs can easily convert partitions back and forth between FAT16, FAT32, NTFS and other file systems, as well as resize, move, and copy partitions without destroying the data they contain. They also allow changes in cluster sizes beyond what the standard Windows tools create.

FAT File System Errors

File system errors can, of course, occur because of hardware problems, but you are more likely to see them result from software crashes and improper system handling. Turning off a system without shutting down Windows properly, for example, can result in errors that cause clusters to be incorrectly listed as in use when they are not. Some of the most common file system errors that occur on FAT partitions are described in the following sections.

Lost Clusters

Probably the most common file system error, lost clusters are clusters the FAT designates as being in use when they actually are not. Most often caused by an interruption of a file system process due to an application crash or a system shutdown, for example, the FAT entry of a lost cluster might contain a reference to a subsequent cluster. However, the FAT chain stemming from the directory entry has been broken somewhere along the line.

Lost clusters appear in the file structure as shown in Table 24.28.

<table>

</tbody>
</table>

The operating system sees a valid chain of clusters in the FAT but no corresponding directory entry to back it up. Programs that are terminated before they can close their open files typically cause this. The operating system usually modifies the FAT chain as the file is written, and the final step when closing is to create a matching directory entry. If the system is interrupted before the file is closed (such as by shutting down the system improperly), lost clusters are the result. Disk repair programs check for lost clusters by tracing the FAT chain for each file and subdirectory in the partition and building a facsimile of the FAT in memory. After compiling a list of all the FAT entries that indicate properly allocated clusters, the program compares this facsimile with the actual FAT. Any entries denoting allocated clusters in the real FAT that do not appear in the facsimile are lost clusters because they are not part of a valid FAT chain.

The utility typically gives you the opportunity to save the data in the lost clusters as a file before it changes the FAT entries to show them as unallocated clusters. If your system crashed or lost power while you were working with a word processor data file, for example, you might be able to retrieve text from the lost clusters in this way. When left unrepaired, lost clusters are unavailable for use by the system, reducing the storage capacity of your drive.

The typical choices you have for correcting lost clusters are to assign them a made-up name or zero out the FAT entries. If you assign them a name, you can at least look at the entries as a valid file and then delete the file if you find it useless. The CHKDSK and SCANDISK programs are designed to fix lost clusters by assigning them names starting with FILE0001.CHK. If more than one lost chain exists, sequential numbers following the first one are used. The lost clusters shown earlier could be corrected by CHKDSK or SCANDISK as shown in Table 24.29.

<td>Last cluster available</td>
</tr>
</tbody>
</table>

As you can see, a new entry was created to match the FAT entries. The name is made up because there is no way for the repair utility to know what the original name of the file might have been.

**Cross-Linked Files**

Cross-linked files occur when two directory entries improperly reference the same cluster in their Link to Start Cluster fields. The result is that each file uses the same FAT chain. Because the clusters can store data from only one file, working with one of the two files can inadvertently overwrite the other file's data.

Cross-linked files would appear in the file structure as shown in Table 24.30.

Table 24.30 Cross-Linked Files

<table>
<thead>
<tr>
<th>Name</th>
<th>Starting Cluster</th>

</thead>
<tbody>
<tr>
<td>USCONST.TXT</td>
<td>1000</td>
<td>4</td>
</tr>
<tr>
<td>PLEDGE.TXT</td>
<td>1002</td>
<td>2</td>
</tr>
</tbody>
</table>

In this case, two files claim ownership of clusters 1002 and 1003, so these files are said to be cross-linked on 1002. When a situation such as this arises, one of the files typically is valid and the other is corrupt, being that only one actual given set of data can occupy a given cluster. The normal repair is to copy both files involved to new names, which duplicates their data separately in another area of the disk, and then delete all the cross-linked files. Deleting them all is important because by deleting only one of them, the FAT chain is zeroed, which further damages the other entries. Then, you can examine the files you copied to determine which one is good and which is corrupt.
Detecting cross-linked files is a relatively easy task for a disk repair utility because it must examine only the partition’s directory entries and not the file clusters themselves. However, by the time the utility detects the error, the data from one of the two files is probably already lost—although you might be able to recover parts of it from lost clusters.

**Invalid Files or Directories**

Sometimes the information in a directory entry for a file or subdirectory can be corrupted to the point at which the entry is not just erroneous (as in cross-linked files) but invalid. The entry might have a cluster or date reference that is invalid, or it might violate the rules for the entry format in some other way. In most cases, disk repair software can correct these problems, permitting access to the file.

**FAT Errors**

As discussed earlier, accessing its duplicate copy can sometimes repair a corrupted FAT. Disk repair utilities typically rely on this technique to restore a damaged FAT to its original state, as long as the mirroring process has not corrupted the copy. FAT32 tables are more likely to be repairable because their more advanced mirroring capabilities make the copy less likely to be corrupted.

An example of a damaged FAT might appear to the operating system as shown in Table 24.31.

<table>
<thead>

</tbody>
</table>

This single error would cause multiple problems to appear. The file USCONST.TXT would now come up as having an allocation error—in which the size in the directory no longer matches the number of clusters in the FAT chain. The file would end after cluster 1001 in this example, and the rest of the data would be missing if you loaded this file for viewing. Also, two lost clusters would exist; that is, 1002 and 1003 appear to have no directory entry that owns them. When multiple problems such as these appear, a single incident of damage is often the cause. The repair in this case could involve copying the data from the backup FAT back to the primary FAT, but in most cases, the backup is similarly damaged. Normal utilities would truncate the file and create an entry for a second file out of the lost clusters. You would have to figure out yourself that they really belong together. This is where having knowledge in data recovery can help over using automated utilities that can’t think for themselves.
FAT File System Utilities

The CHKDSK, RECOVER, and SCANDISK commands are the DOS damaged-disk recovery team. These commands are crude, and their actions sometimes are drastic, but at times they are all that is available or necessary. RECOVER is best known for its function as a data recovery program, and CHKDSK typically is used for inspection of the file structure. Many users are unaware that CHKDSK can implement repairs to a damaged file structure. DEBUG, a crude, manually controlled program, can help in the case of a disk disaster—if you know exactly what you are doing.

SCANDISK is a safer, more automated, more powerful replacement for CHKDSK and RECOVER in Windows 9x/Me. Windows 2000 and XP do not include SCANDISK and instead have beefed up CHKDSK to handle NTFS.

If you are using MS-DOS 5.0 or older, the only disk testing utilities supplied with your version of MS-DOS are CHKDSK and RECOVER. To learn more about how CHKDSK works, see Upgrading and Repairing PCs, 11th Edition, included in electronic form on the DVD packaged with this book.

The RECOVER Command

The DOS RECOVER command is designed to mark clusters as bad in the FAT when the clusters can’t be read properly. When the system can’t read a file because of a problem with a sector on the disk going bad, the RECOVER command can mark the FAT so another file does not use those clusters. When used improperly, this program is highly dangerous. The RECOVER utility has not been included in DOS since version 5 and is not supplied in Windows 9x/Me because its functionality has been replaced by SCANDISK.

Caution

Be very careful when you use RECOVER. Used improperly, it can do severe damage to your files and the FAT. If you enter the RECOVER command without a filename for it to work on, the program assumes you want every file on the disk recovered and operates on every file and subdirectory on the disk. It converts all subdirectories to files, places all filenames in the root directory, and gives them new names like FILE0000.REC, FILE0001.REC, and so on. This process essentially wipes out the file system on the entire disk. Do not use RECOVER without providing a filename for it to work on. This program should be considered as dangerous as the FORMAT command. RECOVER is so notorious for this behavior that older versions of the Norton Utilities had a “recover from DOS RECOVER” option that could sometimes undo the damage caused by improper use of RECOVER.

An improved version of RECOVER that recovers data from a specified file is only one of the command-line programs provided with Windows NT, 2000, and XP. To use this version of RECOVER, which works with both FAT and NTFS file systems, open a command prompt and enter the command as shown here:

RECOVER (drive\folder\filename)

For example, to recover all readable sectors from a file called Mynovel.txt stored in C:\My Documents\Writings, you would enter the following command:

RECOVER C:\My Documents\Writings\Mynovel.txt

Because the NT/2000/XP version of RECOVER requires you to specify a filename and path, it cannot destroy a file system the way the DOS RECOVER command could. However, you should not use wildcards with the NT/2000/XP version of RECOVER. Instead, specify a single filename as shown in this example, or use a third-party tool such as Norton Disk Doctor to check the drive and attempt data recovery from damaged files.

SCANDISK

You should check your FAT partitions regularly for the problems discussed in this chapter and any other difficulties that might arise. By far an easier and more effective solution for disk diagnosis and repair than CHKDSK and RECOVER is the SCANDISK utility, included with DOS 6 and higher versions, as
well as with Windows 9x/Me. This program is more thorough and comprehensive than CHKDSK or RECOVER and can perform the functions of both of them—and a great deal more.

**Note**

The equivalent of SCANDISK in Windows NT/2000 and Windows XP is called CHKDSK, but it is far more powerful than the old MSDOS CHKDSK program. For more information on the old MSDOS CHKDSK program, see *Upgrading and Repairing PCs, 12th Edition*, included in its entirety on the DVD accompanying this book.

SCANDISK is similar to a scaled-down version of third-party disk repair programs such as Norton Disk Doctor, and it can verify both file structure and disk sector integrity. If SCANDISK finds problems, it can repair directories and FATs. If the program finds bad sectors in the middle of a file, it marks the clusters (allocation units) containing the bad sectors as bad in the FAT and attempts to read the file data by rerouting around the defect.

Windows 9x includes both DOS and Windows versions of SCANDISK, which are named SCANDISK.EXE and SCANDSKW.EXE, respectively. Windows scans your drives at the beginning of the operating system installation process and automatically loads the DOS version of SCANDISK whenever you restart your system after turning it off without completing the proper shutdown procedure. You can also launch SCANDISK.EXE from a DOS prompt or from a batch file using the following syntax:

```plaintext
Scandisk x: [/a] [/n] [/p] [dblspacen.nnn/drvspacen.nnn]
```

- `x:` designator of the drive that you want to scan
- `/a` scans all local fixed hard disks
- `/n` noninteractive mode; requires no user input
- `/p` scans only, without correcting errors
- `/custom` runs Scandisk with the options configured in the ```CUSTOM``` section of the Scandisk.ini file
- `dblspacen.nnn` or `drvspacen.nnn` scans a compressed volume file, where `nnn` is replaced by the file extension (such as 001)

The SCANDISK.INI file, located in the C:\WINDOWS\COMMAND directory on a Windows system by default, contains extensive and well-documented parameters you can use to control the behavior of SCANDISK.EXE. Note that the options in the SCANDISK.INI file are applied only to the DOS version of the utility and have no effect on the Windows GUI version.

You also can run the GUI version of the utility by opening the Start menu and selecting Programs, Accessories, System Tools. Both versions scan and repair the FAT and the directory and file structures, repair problems with long filenames, and scan volumes that have been compressed with DriveSpace or DoubleSpace.

SCANDISK provides two basic testing options: Standard and Thorough. The difference between the two is that the Thorough option causes the program to scan the entire surface of the disk for errors in addition to the items just mentioned. You also can select whether to run the program interactively or let it automatically repair any errors it finds.

The DOS and Windows versions of SCANDISK also test the FAT in different ways. The DOS version scans and, if necessary, repairs the primary copy of the file allocation table. After this, it copies the repaired version of the primary to the backup copy. The Windows version, however, scans both copies of the FAT. If the program finds discrepancies between the two copies, it uses the data from the copy that it judges to be correct and reassembles the primary FAT using the best data from both copies. If the FAT information is not reconstructed correctly, some or all of your data might become inaccessible.

SCANDISK also has an Advanced Options dialog box that enables you to set the following parameters:

- Whether the program should display a summary of its findings
- Whether the program should log its findings
How the program should repair cross-linked files (two directory entries pointing to the same cluster)

How the program should repair lost file fragments

Whether to check files for invalid names, dates, and times

Although SCANDISK is good, and is certainly a vast improvement over the old DOS CHKDSK, I recommend using one of the commercial packages, such as the Norton Utilities (included with Norton SystemWorks), for any major disk problems. These utilities go far beyond what is included in DOS or Windows.

**Disk Defragmentation**

The entire premise of the FAT file systems is based on the storage of data in clusters that can be located anywhere on the disk. This enables the computer to store a file of nearly any size at any time.

The process of following a FAT chain to locate all the clusters holding the data for a particular file can force the hard disk drive to access many locations on the disk. Because of the physical work involved in moving the disk drive heads, reading a file that is heavily fragmented in this way is slower than reading one that is stored on consecutive clusters.

As you regularly add, move, and delete files on a disk over a period of time, the files become increasingly fragmented, which can slow down disk performance. You can relieve this problem by periodically running a disk defragmentation utility on your drives, such as the one included with Windows 9x. When you run Disk Defragmenter, the program reads each of the files in the disk, using the FAT table to access its clusters, wherever they might be located.

The program then writes the file to a series of contiguous clusters and deletes the original. By progressively reading, erasing, and writing files, the program eventually leaves the disk in a state where all its files exist on contiguous clusters. As a result, the drive is capable of reading any file on the disk with a minimum of head movement, thus providing what is often a noticeable performance increase.

The Windows Defragmentation utility provides this basic defragmenting function. It also enables you to select whether you want to arrange the files on the disk to consolidate the empty clusters into one contiguous free space (which takes longer). The Windows 98/Me version adds a feature that examines the files on the disk and arranges them with the most frequently used program files grouped together at the front of the disk, which can make programs load more quickly.

To show how defragmenting works, see the example of a fragmented file shown in Table 24.32.

</tbody>
</table>

In the preceding example, the file USCONST.TXT is fragmented in two pieces. If you ran a defragmenting program, the files would be read off the disk and rewritten in a contiguous fashion. One possible outcome is shown in Table 24.33.

Table 24.33 Defragmented File

<table>
<thead>
<tr>
<th>Name</th>
<th>Starting Cluster</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLEDGE.TXT</td>
<td>1004</td>
<td>2</td>
</tr>
<tr>
<td>USCONST.TXT</td>
<td>1000</td>
<td>4</td>
</tr>
</tbody>
</table>

Although it doesn’t look like much was changed, you can see that now both files are in one piece, stored one right after the other. Because defragmenting involves reading and rewriting a possibly large number of files on your drive, it can take a long time, especially if you have a large drive with a lot of fragmented files and not very much free working space on the drive.

Third-party defragmentation utilities, such as the Speed Disk program included in the Norton Utilities, provide additional features, such as the capability to select specific files that should be moved to the front of the disk. Speed Disk also can defragment the Windows swap file and files that are flagged with the system and hidden attributes, which Disk Defragmenter will not touch.
Caution
Although the disk-defragmentation utilities included with Windows and third-party products are usually quite safe, you should always be aware that defragmenting a disk is an inherently dangerous procedure. The program reads, erases, and rewrites every file on the disk and has the potential to cause damage to your data when interrupted improperly. Although I have never seen a problem result from the process, an unforeseen event—such as a power failure—during a defragmentation procedure can conceivably be disastrous. I strongly recommend that you always run a disk-repair utility, such as SCANDISK, on your drives before defragmenting them and have a current backup ready.

Windows NT 4.0 does not include a defragmentation utility, but Windows 2000 and Windows XP do include such a utility. Note that third-party defragmentation utilities available for recent and current versions of Windows, such as Golden Bow Systems’ VoxtXP (www.voxt.com), are often faster and offer more features than Windows’s own defragmentation programs.

Third-Party Programs
When you get a Sector not found error reading drive C:, the best course of action is to use one of the third-party disk-repair utilities on the market, rather than DOS’s RECOVER or even SCANDISK. The Norton Utilities by Symantec (also included in Norton SystemWorks) stands as perhaps the premier data recovery package on the market today. This package is comprehensive and automatically repairs most types of disk problems.

Norton Utilities and Norton SystemWorks
Programs such as Norton Disk Doctor can perform much more detailed repairs with a greater amount of safety. Disk Doctor preserves as much of the data in the file as possible and can mark the FAT so the bad sectors or clusters of the disk are not used again. These programs also save Undo information, enabling you to reverse any data recovery operation.

Disk Doctor is part of Symantec’s Norton Utilities package, which includes a great many other useful tools. For example, Norton Utilities has an excellent sector editor (Norton Disk Editor) that enables you to view and edit any part of a disk, including the master and volume boot records, FATs, and other areas that fall outside the disk’s normal data area. Currently, no other program is as comprehensive or as capable of editing disks at the sector level. The disk editor included with Norton Utilities can give the professional PC troubleshooter or repairperson the ability to work directly with any sector on the disk, but this does require extensive knowledge of sector formats and disk structures. The documentation with the package is excellent and can be very helpful if you are learning data recovery on your own.

Note
Data recovery is a lucrative service that the more advanced technician can provide. People are willing to pay much more to get their data back than to replace a hard drive.

You also can create a rescue disk for restarting your system and testing the drive in case of emergencies, unerase accidentally deleted files (even if the Recycle Bin was bypassed), and unformat accidentally formatted drives.

Norton Utilities is now available in version 2003 as part of Norton SystemWorks 2003 (for Windows 98/Me/NT/2000/XP). SystemWorks 2003 also includes Norton Anti-Virus and Norton CleanSweep uninstaller; the Professional version also includes Norton Ghost disk imaging. Some of the programs provided with Norton Utilities are designed to be run from the command line or from a DOS prompt, such as the following:

- Norton Disk Doctor (NDD.EXE)
- Disk Editor (DISKEDIT.EXE)
- UnErase (UNERASE.EXE)
- UnFormat (UNFORMAT.EXE)
- Rescue Restore (RESCUE.EXE)
However, most Norton Utilities programs are designed to be run from within the Windows GUI. You must use the Windows GUI to work on NTFS-based drives. You should not use older versions of Norton Utilities, such as version 8.0 (designed for Windows 3.1 and MS-DOS), with 32-bit versions of Windows because of the possibility of data loss due to a lack of support for long filenames and large drives.

**SpinRite 5**

The SpinRite 5 program from Gibson Research (http://grc.com) provides testing of both IDE and SCSI hard drives as well as removable-media drives of all sizes that have FAT-type file systems, including FAT32. During testing, SpinRite 5 statistically analyzes hard-to-read disk sectors to determine their original contents; it then moves the data to a properly working area of the disk. This process takes longer than with a program such as DiskDoctor, but for heavily damaged disks and drives for which no backup is available, this process can be more successful at recovering data. Another handy feature of SpinRite 5 is its capability to query your drive’s partition table to determine the disk geometry originally used to set up the disk. This enables you to access data on a disk even if the factory disk geometry values were not used to prepare the disk with FDISK and were not written down for future use.

**File Systems and Third-Party Disk Utilities**

The most important consideration when you purchase third-party disk utilities is to choose products that support your file system. For example, Norton Utilities supports both FAT (including FAT32) and NTFS file systems. On the other hand, SpinRite 5 supports all FAT file systems but not NTFS. Never use a disk utility not designed for your file system, and never use an out-of-date disk utility (designed for an earlier operating system) on your disk. In both cases, you could cause irreparable damage to the data on your drive.

**New Technology File System**

New Technology File System (NTFS) is the native file system of Windows NT, Windows 2000, and Windows XP. Windows 2000 and Windows XP use an enhanced version of NTFS called NTFS 5 or NTFS 2000; Windows NT 4.0 must have Service Pack 4 or above installed to be capable of accessing an NTFS 5/NTFS 2000 disk. Although NT/2000/XP support FAT partitions (and Windows 2000/XP even support FAT32), NTFS provides many advantages over FAT, including long filenames, support for larger files and partitions, extended attributes, and increased security. NTFS, like all of Windows NT, was newly designed from the ground up. Backward-compatibility with previous Microsoft operating systems was not a concern because the developers were intent on creating an entirely new 32-bit platform. As a result, no operating systems other than Windows NT and Windows 2000/XP, which are based on Windows NT, can read NTFS partitions.

This is an important consideration. All the other Windows operating systems are fundamentally based on DOS and give you the alternative of booting to a DOS prompt in special situations. Whether you have to run a special DOS utility to configure a piece of hardware or perform an emergency disk repair, the DOS option is always there.

Windows NT/2000/XP are not DOS based. You can open a window that provides a DOS-like command prompt in Windows NT/2000/XP, but this is actually a DOS emulation—not a true shell. You can’t boot the system to a command prompt, avoiding the GUI, as you can with Windows 9x unless you install the Windows 2000 or Windows XP Recovery Console. As the name implies, the Recovery Console is designed for system repair and maintenance procedures, not for routine use. You can, of course, bypass NT/2000/XP entirely by starting the system with a DOS boot disk, but if you have NTFS partitions on your drives, you can’t access them from the DOS prompt.

NTFS supports filenames of up to 255 characters, using spaces, multiple periods, and any other standard characters except the following: *?\:<>.1. Because NTFS file offsets are 64 bits long, files and partitions can be truly enormous—up to 16 EiB (exbibytes) in size (1 EiB = 2^60 bytes = 1,048,576TiB)! To give you an idea of just how much data this is, it was estimated that all the words ever spoken by humans throughout history would occupy 5 EiB of storage.
Since Windows NT 3.51, NTFS has also supported compression on a file-by-file (or folder-by-folder) basis through each file or folder's properties sheet. No third-party program, such as WinZip or PKZip, is needed to compress or decompress files stored on an NTFS drive. NTFS 5 also supports encryption on a file-by-file or folder-by-folder properties sheet.

**Tip**
To access advanced file attributes such as compression, encryption, and indexing, right-click the file or folder, select Properties, and click the Advanced button to bring up the Advanced properties dialog box.

### NTFS Architecture

Although NTFS partitions are very different from FAT partitions internally, they do comply with the extra-partitional disk structures described earlier in this chapter. NTFS partitions are listed in the master partition table of a disk drive's master boot record, just like FAT partitions, and they have a volume boot record as well, although it is formatted somewhat differently.

When a volume is formatted with NTFS, system files are created in the root directory of the NTFS volume. These system files can be stored at any physical location on the NTFS volume. This means that damage to any specific location on the disk will probably not render the entire partition inaccessible.

Typically, 12 NTFS system files (often referred to as *metadata* files) are created when you format an NTFS volume. Table 24.34 shows the names and descriptions for these files.

#### Table 24.34 NTFS System Files

<table>
<thead>
<tr>
<th>Filename</th>
<th>Meaning</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$mft</td>
<td>Master file table (MFT)</td>
<td>Contains a record for every file on the NTFS volume in its Data attribute</td>
</tr>
<tr>
<td>$mftmirr</td>
<td>Master file table2 (MFT2)</td>
<td>Mirror of the MFT used for recoverability purposes; contains the first four records in $mft or the first cluster of $mft, whichever is larger</td>
</tr>
<tr>
<td>$badclus</td>
<td>Bad cluster file</td>
<td>Contains all the bad clusters on the volume</td>
</tr>
<tr>
<td>$bitmap</td>
<td>Cluster allocation bitmap</td>
<td>Contains the bitmap for the entire volume, showing which clusters are used</td>
</tr>
<tr>
<td>$boot</td>
<td>Boot file</td>
<td>Contains the volume’s bootstrap if the volume is bootable</td>
</tr>
<tr>
<td>$attrdef</td>
<td>Attribute definitions table</td>
<td>Contains the definition of all system- and user-defined attributes on the volume</td>
</tr>
<tr>
<td>$logfile</td>
<td>Log file</td>
<td>Logs file transactions; used for recoverability purposes</td>
</tr>
<tr>
<td>$quota</td>
<td>Quota table</td>
<td>Table used to indicate disk quota usage for each user on a volume; used in NTFS 5</td>
</tr>
<tr>
<td>$upcase</td>
<td>Upcase table</td>
<td>Table used for converting uppercase and lowercase characters to the matching uppercase Unicode characters</td>
</tr>
<tr>
<td>$volume</td>
<td>Volume</td>
<td>Contains volume information, such as volume name and version</td>
</tr>
<tr>
<td>$extend</td>
<td>NTFS extension file</td>
<td>Stores optional extensions, such as quotas, object identifiers, and reparse point data</td>
</tr>
<tr>
<td>{no name}</td>
<td>Root filename index</td>
<td>The root folder (directory)</td>
</tr>
</tbody>
</table>

An NTFS partition is based on a structure called the master file table (MFT). The MFT concept expands on that of the FAT. Instead of using a table of cluster references, the MFT contains much more detailed information about the files and directories in the partition. In some cases, it even contains the files and directories themselves.
The first record in the MFT is called the descriptor, which contains information about the MFT itself. The volume boot record for an NTFS partition contains a reference that points to the location of this descriptor record. The second record in the MFT is a mirror copy of the descriptor, which provides fault tolerance, should the first copy be damaged.

The third record is the log file record. All NTFS transactions are logged to a file that can be used to restore data in the event of a disk problem. The bulk of the MFT consists of records for the files and directories stored on the partition. NTFS files take the form of objects that have both user- and system-defined attributes. Attributes on NTFS partitions are more comprehensive than the few simple flags used on FAT partitions. All the information on an NTFS file is stored as attributes of that file. In fact, even the file data itself is an attribute. Unlike FAT files, the attributes of NTFS files are part of the file itself; they are not listed separately in a directory entry. Directories exist as MFT records as well, but they consist mainly of indexes listing the files in the directory—they do not contain the size, date, time, and other information about the individual files.

Thus, an NTFS drive's MFT is much more than a cluster list, like a FAT; it is actually the primary data storage structure on the partition. If a file or directory is relatively small (less than approximately 1,500 bytes), the entire file or directory might even be stored in the MFT. For larger amounts of storage, the MFT record for a file or directory contains pointers to external clusters in the partition. These external clusters are called extents. All the records in the MFT, including the descriptors and the log file, are capable of using extents for storage of additional attributes. The attributes of a file that are part of the MFT record are called resident attributes, whereas those stored in extents are called nonresident attributes.

**NTFS 5 (NTFS 2000)**

Along with Windows 2000 came a new variation of NTFS called NTFS 5 (also called NTFS 2000); NTFS 5 is also used by Windows XP. This update of the NT file system includes several new features that are exploited and even required by Windows 2000 and Windows XP. Because of this, when you install Windows 2000 or Windows XP, any existing NTFS volumes automatically are upgraded to NTFS 5 (there is no way to override this option). If you also run Windows NT versions earlier than Windows NT 4 Service Pack 4 (SP4), NT 4 is no longer capable of accessing the NTFS 5 volumes. If you want to run both NT 4 and Windows 2000 or Windows XP on the same system (as in a dual-boot configuration), you must upgrade NT 4 by installing Service Pack 4 or later. An updated NTFS.SYS driver in Service Pack 4 enables NT 4 to read from and write to NTFS 5 volumes.

New features of the NTFS 5 file system include:

- **Disk quotas.** System administrators can limit the amount of disk space users can consume on a per-volume basis. The three quota levels are Off, Tracking, and Enforced.
- **Encryption.** NTFS 5 can automatically encrypt and decrypt files as they are read from and written to the disk (not available in Windows XP Home Edition).
- **Reparse points.** Programs can trap open operations against objects in the file system and run their own code before returning file data. This can be used to extend file system features such as mount points, which you can use to redirect data read and written from a folder to another volume or physical disk.
- **Sparse files.** This feature enables programs to create very large files as placeholders but to consume disk space by adding to the files only as necessary.
- **USN (Update Sequence Number) Journal.** Provides a log of all changes made to files on the volume.
- **Mounted drives.** You can attach volumes including drives and folders to an empty folder stored on an NTFS drive. For example, you can create a folder on one drive that allows you to access content stored on another drive.

Because these features—especially the USN Journal—are required for Windows 2000 to run, a Win2000/Server 2003 domain controller must use an NTFS 5 partition as the system volume.
**NTFS Changes in Windows XP**

The location of the MFT has changed in Windows XP versus Windows 2000 and Windows NT. In Windows 2000 and Windows NT, the MFT is typically located at the start of the disk space used by the NTFS file system. In Windows XP, the $logfile and $bitmap metadata files are located 3GB from the start of the disk space used by NTFS. As a result, system performance has been increased by 5%–8% in Windows XP over Windows 2000 or Windows NT.

Another improvement in Windows XP’s implementation of NTFS is the amount of MFT information read into memory. During bootup, Windows XP reads only a few hundred kilobytes of MFT information if all drives are formatted with NTFS. However, if some or all of the drives are formatted with FAT32, many megabytes of information (the amount varies by the number of drives and the size of the drives) must be read during bootup. Thus, using NTFS utilizes system memory more efficiently.

**NTFS Compatibility**

Although NTFS partitions are not directly accessible by DOS and other operating systems, Windows NT/2000 is designed for network use, so other operating systems are expected to be capable of accessing NTFS files via the network. For this reason, NTFS continues to support the standard DOS file attributes and the 8.3 FAT naming convention.

One of the main reasons for using NTFS is the security it provides for its files and directories. NTFS security attributes are called permissions and are designed to enable system administrators to control access to files and directories by granting specific rights to users and groups. This is a much more granular approach than the FAT file system attributes, which apply to all users.

However, you can still set the FAT-style attributes on NTFS files using the standard Windows NT/2000 file management tools, including Windows NT/2000 Explorer and even the command-prompt ATTRIB command. When you copy FAT files to an NTFS drive over the network, the FAT-style attributes remain in place until you explicitly remove them. This can be an important consideration because the FAT-style attributes take precedence over the NTFS permissions. A file on an NTFS drive that is flagged with the FAT read-only attribute, for example, can’t be deleted by a Windows NT/2000 user, even if that user has NTFS permissions that grant her full access.

To enable DOS and 16-bit Windows systems to access files on NTFS partitions over a network, the file system maintains an 8.3 alias name for every file and directory on the partition. The algorithm for deriving the alias from the long filename is the same as that used by Windows 95’s VFAT. Windows NT/2000 also provides its FAT partitions with the same type of long filename support used by VFAT, allocating additional directory entries to store the long filenames as necessary.

**Creating NTFS Drives**

NTFS is for use on hard disk drives. You can’t create an NTFS floppy disk (although you can format removable media, such as Iomega Zip and Jaz cartridges to use NTFS). Three basic ways to create an NTFS disk partition are as follows:

- Create a new NTFS volume out of unpartitioned disk space during the Windows NT/2000 installation process or after the installation with the Disk Administrator utility.
- Format an existing partition to NTFS (destroying its data in the process), using the Windows NT Format dialog box (accessible from Windows NT Explorer or Disk Administrator) or the FORMAT command (with the /fs:ntfs switch) from the command prompt.
- Convert an existing FAT partition to NTFS (preserving its data) during the Windows NT/2000 installation process or after the installation with the command-line CONVERT utility.
NTFS Tools

Because it uses a fundamentally different architecture, virtually none of the troubleshooting techniques outlined earlier in this chapter are applicable when dealing with NTFS partitions, nor can the disk utilities intended for use on FAT partitions address them. Windows NT has a rudimentary capability to check a disk for file system errors and bad sectors with its own version of CHKDSK, but apart from that, the operating system contains no other disk repair or defragmentation utilities. Windows 2000 and Windows XP include a command-line and GUI version of CHKDSK and also include a defragmenting tool that is run from the Windows Explorer GUI. Windows XP Professional also includes DSKPROBE, a direct disk sector editor, in its Windows Support Tools (the Windows 2000 Resource Kit also contains DSKPROBE).

One difference between Windows 2000/XP's CHKDSK and Windows 9x/Me's SCANDISK is that CHKDSK cannot fix file system errors if it is run within the Windows GUI. If you run CHKDSK and select the Automatically Fix File System Errors option, you must schedule CHKDSK to run at the next system startup. You can run CHKDSK without this option to find file system problems; you can also run CHKDSK within the Windows GUI to look for and attempt to fix bad sectors.

Tip

You can use the FSUTIL command-line program in Windows 2000 and Windows XP to learn more about a particular drive's file system, including whether you need to run CHKDSK or a third-party disk repair tool. For example, to determine whether drive D: is dirty (has file system errors requiring repair), you would open a Windows 2000/XP command prompt and enter this command:

FSUTIL DIRTY QUERY D:

For more examples of FSUTIL commands and syntax, enter FSUTIL with no options at a Windows 2000/XP command prompt.

The NTFS file system, however, does have its own automatic disk repair capabilities. In addition to Windows NT/2000/XP's fault-tolerance features, such as disk mirroring (maintaining the same data on two separate drives) and disk striping with parity (splitting data across several drives with parity information for data reconstruction), the OS has two features to help improve reliability:

■ Transaction management
■ Cluster remapping

NTFS can roll back any transaction (its term for a change to a file stored on an NTFS volume) if it isn't completed properly due to disk errors, running out of memory, or errors such as removing media or disconnecting a device before the transaction process is complete. Each transaction has five steps:

1. NTFS creates a log file of the metadata operations of the transaction (file updates, erasure, and so on) and caches the file in system memory.
2. NTFS stores the actual metadata operations in memory.
3. NTFS marks the transaction record in the log file as committed.
4. NTFS saves the log file to disk after the transaction is complete.
5. NTFS saves the actual metadata operations to disk after the transaction is complete.

This process is designed to prevent random data (lost clusters) on NTFS drives.

With cluster remapping, when Windows (NT/2000/XP) detects a bad sector on an NTFS partition, it automatically remaps the data in that cluster to another cluster. If the drive is part of a fault-tolerant drive array, any lost data is reconstructed from the duplicate data on the other drives.
Despite these features, however, there is still a real need for third-party disk repair and defragmentation utilities for Windows NT/2000/XP. These were scarce when Windows NT was first released, but third-party utilities that can repair and defragment NTFS drives are now widely available. One I recommend is Norton Utilities 2003 (also included in Norton SystemWorks 2003 and Norton SystemWorks Pro 2003) by Symantec, which works with Windows 98, Windows Me, Windows 2000, and Windows XP. Earlier versions work with Windows NT 4.0 and Windows 95. If you are looking for even faster defragmentation, Golden Bow's VoptXP (which also supports Windows 9x, Me, and 2000) is a longtime favorite.

**High Performance File System**

The High Performance File System (HPFS) was first introduced in OS/2 version 1.2 and included many additional features over the existing FAT16 system available at the time. HPFS was also supported in Windows NT 3.x versions but not any later versions. In many ways, HPFS was the predecessor to the NTFS that later debuted in Windows NT.

For more information about HPFS, see the Technical Reference section of the DVD packaged with this book.

**Data Recovery**

Recovering lost data can be as simple as opening the Recycle Bin, or it might require spending hundreds of dollars on specialized data recovery software or services. In the worst-case scenario, you might even need to send your drive to a data recovery center. Several factors affect the degree of difficulty you can have in recovering your data, including

- How the data was deleted
- Which file system was used by the drive on which the data was stored
- Whether the drive uses magnetic, optical, magneto-optical, or flash memory to store data
- Which version of Windows or other OS you use
- Whether you already have data-protection software installed on your system
- Whether the drive has suffered physical damage to heads, platters, or its circuit board

**The Windows Recycle Bin and File Deletion**

The simplest data recovery of all takes place when you send files to the Windows Recycle Bin (a standard part of Windows since Windows 95). Pressing the Delete key when you have a file or group of files highlighted in Windows Explorer or My Computer or clicking the Delete button sends files to the Recycle Bin. Although a file sent to the Recycle Bin is no longer listed in its normal location by Windows Explorer, the file is actually protected from being overwritten. By default, Windows 95 and above reserve 10% of the disk space on each hard disk for the Recycle Bin (removable-media drives don't have a Recycle Bin). Thus, a 10GB drive reserves about 1GB for its Recycle Bin. In this example, as long as less than 1GB of files has been sent to the Recycle Bin, a so-called deleted file is protected by Windows. However, after more than 1GB of files has been sent to the Recycle Bin, Windows allows the oldest files to be overwritten. Thus, the quicker you realize that a file has been sent to the Recycle Bin, the more likely it is you can retrieve it.

To retrieve a file from the Recycle Bin, open the Recycle Bin, select the file, right-click it, and select Restore. Windows lists the file in its original location and removes it from the Recycle Bin.

If you hold down the Shift key when you select Delete or press the Delete key, the Recycle Bin is bypassed. Retrieving lost data at this point requires third-party data recovery software.
Recovering Files That Are Not in the Recycle Bin

The Recycle Bin is a useful first line of defense against data loss, but it is quite limited. As you learned in the previous section, it can be bypassed when you select files for deletion, and files stored in the Recycle Bin are eventually kicked out by newer deleted files. Also, the Recycle Bin isn’t used for files deleted from a command prompt or when an older version of a file is replaced by a newer version.

Products such as Norton UnErase (part of the Norton Utilities and Norton SystemWorks) are necessary if you want to retrieve files not in the Recycle Bin. However, the effectiveness of Norton UnErase and how you should use it depends on the version of Windows you use and the file system used by your drives.

Norton UnErase and Norton Protected Recycle Bin—Win9x/Me

With Windows 9x/Me, which use the FAT file system, retrieving data from a drive that doesn’t have Norton Utilities installed isn’t difficult. However, installing Norton Utilities before you start to delete files that you might want to retrieve makes it even easier. You can run Norton UnErase from the bootable CD included in current versions and run UnErase as a command-prompt program if you don’t have it already installed and need to retrieve erased data. You will need to provide the first letter of each file you want to unerase.

**Caution**

Do not install data-recovery software to a drive you are attempting to retrieve data from because you might overwrite the data you are attempting to retrieve. If you are trying to recover data from your Windows startup drive, install another hard disk into your system, configure it as a boot drive in the system BIOS, install a working copy of Windows on it, boot from that drive, and install your data recovery software to that drive. If possible, install a drive large enough (at least 10GB or larger) so that you have several GB of free space on it for storing recovered data.

However, if you have already installed Norton Utilities, you probably have the Norton Protected Recycle Bin on your desktop in place of the regular Recycle Bin. Compared to the Windows standard-model Recycle Bin, the Norton Protected Recycle Bin protects files that have been replaced with newer versions and files that were deleted from a command prompt. To retrieve a file stored in the Norton Protected Recycle Bin, open the Recycle Bin, select the file you want to retrieve, right-click it, and select Retrieve to put it back in its original location.

Alternatively, you can start the Norton Unerase Wizard from the Norton Utilities menu. You can search for recently deleted files (these files are stored in the Recycle Bin), all protected files on local drives (also stored in the Recycle Bin), and any recoverable files on local drives. When you select the last option, you can narrow down the search with wildcards or file types and specify which drives to search. You must supply the first letter of the filename for files that were not stored in the Recycle Bin; you can also see which files were deleted by a particular program. To undelete a file with the Unerase Wizard, select the file, provide the first letter of the filename if necessary, click Quick View to view the file (if your file viewer supports the file format), and click Recover to restore the file to its original location.

With Windows 9x/Me, you can search both hard and removable-media (floppy, flash memory) drives for lost files, although the Recycle Bin works only for hard drives.

Norton UnErase and Norton Protected Recycle Bin—Win 2000/XP

Norton UnErase and Norton Protected Recycle Bin work in a similar fashion with Windows 2000/XP as with Windows 9x/Me, but with a significant exception: The Unerase Wizard can search only hard drives. Removable-media drives are not supported.
Tip
If you want to use Norton Unerase Wizard to retrieve data from a floppy drive and don’t have Windows 9x/Me installed on your system, start your computer with the Norton bootable CD and run Unerase from the CD startup menu.
If you have a dual-boot system that can run Windows 9x/Me and Windows 2000/XP and you also want to use Norton Unerase Wizard with Zip, USB, and flash memory devices, start the computer with Windows 9x/Me, install Norton Utilities or SystemWorks under Windows 9x/Me, and start your computer with Windows 9x/Me if you need to search removable media drives for lost data.

Alternatives to Norton UnErase
VCOM’s System Suite 4.0 (previously sold by Ontrack) is an integrated utility suite that offers an undelete feature similar in many ways to Norton UnErase. However, System Suite’s FileUndelete works with removable-media drives as well as hard drives under all supported versions of Windows, including Windows XP.

Although it’s not an automatic tool, you can use Norton’s Disk Editor (DISKEDIT.COM) to retrieve lost data from hard, floppy, and most types of removable-media drives under any file system and most operating systems, including Linux. See the section “Using the Norton Disk Editor” later in this chapter.

Undeleting Files in NTFS
Because the file structure of NTFS is much more complex than any FAT file system version and some files might be compressed using NTFS’s built-in compression, you should use an NTFS-specific file undeletion program to attempt to recover deleted files from an NTFS drive. For example, you should use a version of Norton Utilities or Norton SystemWorks compatible with NTFS, such as the 2002 or later versions. Also, you should enable the Norton Protection feature, which stores deleted files for a specified period of time before purging them from the system. Using Norton Protection will greatly enhance Norton UnErase’s capability to recover deleted files.

If you need to recover deleted files and have not already installed an undelete program such as Norton Utilities or Norton SystemWorks’ Norton UnErase, you should consider a standalone file recovery program, such as

- **Active Undelete.** This series of products also works with flash memory cards; more information and a free demo are available from [http://www.active-undelete.com](http://www.active-undelete.com).
- **Restorer 2000.** Available in FAT, NTFS, and Professional versions; more information and a free demo are available from [http://www.bitmart.net/r2k.shtml](http://www.bitmart.net/r2k.shtml).
- **Ontrack EasyRecovery.** More information and a free demo are available from [http://www.ontrack.com](http://www.ontrack.com).

Tip
Some file-undelete products for NTFS can undelete only files created by the currently logged-in user, whereas others require the administrator to be logged in. Check the documentation for details, particularly if you are trying to undelete files from a system with more than one user.

Retrieving Data from Partitioned and Formatted Drives
When a hard disk, floppy disk, or removable-media drive has been formatted, its file allocation table, which is used by programs such as Norton UnErase or VCOM System Suite’s FileUndelete to determine the location of files, is lost. If a hard drive has been repartitioned with FDISK or another partitioning program (such as Windows 2000/XP’s Disk Management), the original file system and partition information is lost (as is the FAT).
In such cases, more powerful data-recovery tools must be used to retrieve data. To retrieve data from an accidentally formatted drive, you have two options:

- Use a program that can unformat the drive.
- Use a program that can bypass the newly created FAT and read disk sectors directly to discover and retrieve data.

To retrieve data from a drive that has been partitioned, you must use a program that can read disk sectors directly.

**Norton Unformat and Its Limitations**

Norton Utilities and Norton SystemWorks offer Norton Unformat, which can be launched from the bootable CD to unformat an accidentally formatted FAT drive. However, Norton Unformat has significant limitations with today's file systems and drive types, including the following:

- **Norton Unformat doesn’t support NTFS drives.** This means many Windows 2000 and XP-based systems can’t use it for data recovery.
- **Norton Unformat cannot be used with drives that require device drivers to function, such as removable-media drives.**
- **Norton Unformat works best if the Norton Image program has been used to create a copy of the FATs and root directory.** If the image file is out-of-date, Unformat might fail; if the image file is not present, Unformat cannot restore the root directory and the actual names of folders in the root directory will be replaced by sequentially numbered folder names.
- **Norton Unformat cannot copy restored files to another drive or folder.** It restores data back to the same drive and partition. If Unformat uses an out-of-date file created by Norton Image to determine where data is located, it could overwrite valid data on the drive being unformatted.

For these reasons, Norton Unformat is not the most desirable method for unformatting a drive. You can use the powerful, but completely manual, Norton Disk Editor (DISKEDIT) to unformat a drive or retrieve data from a formatted drive, but other alternatives are simpler.

**Retrieving Lost Data to Another Drive**

Many products on the market can retrieve lost data to another drive, whether the data loss was due to accidental formatting or disk partitioning. One of the best and most comprehensive products is the EasyRecovery product line from Ontrack DataRecovery Services, a division of Kroll Ontrack, Inc. The EasyRecovery product line includes the following products:

- **EasyRecovery DataRecovery.** Recovers data from accidentally formatted or deleted hard, floppy, and removable-media drives and repairs damaged or corrupted Zip and Microsoft Word files. Local and network folders can be used for recovered files.
- **EasyRecovery FileRepair.** Repairs and recovers data from damaged or corrupted Zip and Microsoft Office (Word, Excel, Access, PowerPoint, and Outlook) files. Local and network folders can be used for recovered files.
- **EasyRecovery Professional.** Combines the features of DataRecovery and FileRepair and adds features such as file type search, RawRecovery, and user-defined partition parameters to help recover data from more severe forms of file system corruption and accidental partitioning. A free trial version displays files that can be recovered (and repairs and recovers Zip files at no charge); it can be downloaded from the Ontrack Web site (http://www.ontrack.com).

An earlier version of EasyRecovery Data Recovery Lite can recover up to 50 files and is included as part of VCOM’s System Suite (previously sold by Ontrack).
When you start EasyRecovery Professional, you can choose from several recovery methods, including these:

- **DeletedRecovery.** Recovers deleted files
- **FormatRecovery.** Recovers files from accidentally formatted drives
- **RawRecovery.** Recovers files with direct sector reads using file-signature matching technology
- **AdvancedRecovery.** Recovers data from deleted or corrupted partitions

In each case, you need to specify another drive to receive the retrieved data. This read-only method preserves the contents of the original drive and enables you to use a different data-recovery method if the first method doesn’t recover the desired files.

Which options are best for data recovery? Table 24.35 shows the results of various data-loss scenarios and recovery options when EasyRecovery Professional was used to recover data from a 19GB logical drive formatted with the NTFS file system under Windows XP.

### Table 24.35 Data Recovery Options and Results with EasyRecovery Professional

<table>
<thead>
<tr>
<th>Type of Data Loss</th>

<tr>
<td>RawRecovery</td>
<td>Partial</td>
<td>Nonfragmented files recovered.</td>
<td>Original directory structure and filenames lost; each file type stored in a separate folder and files numbered sequentially.</td>
<td></td>
</tr>
<tr>
<td>Formatted, repartitioned drive formatted as NTFS (18.8GB Disk 2)</td>
<td>AdvancedRecovery</td>
<td>No</td>
<td>Could not locate any files to recover.</td>
<td>Original directory structure and filenames lost; each file type stored in a separate folder and files numbered sequentially.</td>
</tr>
</tbody>
</table>
As Table 24.35 makes clear, as long as the data areas of a drive are not overwritten, complete data recovery is usually possible—even if the drive has been formatted or repartitioned. Thus, it’s critical that you react quickly if you suspect you have partitioned or formatted a drive containing valuable data. The longer you wait to recover data, the less data will be available for recovery. In addition, if you must use a sector-by-sector search for data (a process called RawRecovery by Ontrack), your original folder structure and long filenames will not be saved. You will therefore need to re-create the desired directory structure and rename files after you recover them—a very tedious process.

**Tip**

If you use EasyRecovery Professional or EasyRecovery DataRecovery to repair damaged Zip or Microsoft Office files, use the Properties menu to select a location for repaired files (the original location or another drive or folder). By default, repaired Outlook files are copied to a different folder, whereas other file types are repaired in place unless you specify a different location.

As you can see from this example, dedicated data-recovery programs such as Ontrack EasyRecovery Professional are very powerful. However, they are also very expensive. If you have Norton Utilities or Norton SystemWorks and don’t mind taking some time to learn about disk structures, you can perform data recovery with the Norton Disk Editor.

**Using the Norton Disk Editor**

In my PC Hardware (Upgrading and Repairing) and Data Recovery/Computer Forensics seminars, I frequently use the Norton Disk Editor—an often-neglected program that’s part of the Norton Utilities and Norton SystemWorks—to explore drives. I also use Disk Editor to retrieve lost data. Because Disk Editor is a manual tool, it can sometimes be useful even when friendlier automatic programs don’t work correctly or are unavailable. For example, in physical sector mode, Disk Editor can be used with any drive regardless of what file system was used, since at that level it is working underneath the OS. Additionally, because Disk Editor displays the structure of your drive in a way other programs don’t, it’s a perfect tool for learning more about disk drive structures as well as recovering lost data. This section discusses two of the simpler procedures you can perform with Disk Editor:

- Undeleting a file on a floppy disk
- Copying a deleted file on a hard disk to a different drive

If you have Norton SystemWorks, SystemWorks Professional, or Norton Utilities for Windows, you have Norton Disk Editor. To determine whether it’s installed on your system, look in the Norton Utilities folder under the Program Files folder for the following files: DISKEDIT.EXE and DISKEDIT.HLP.

If you don’t find these files on your hard disk, you can run them directly from the Norton installation CD. If you have SystemWorks or SystemWorks Professional, look for the CD folder called \NU to locate these files.

Disk Edit is a command prompt program designed primarily to access FAT-based file systems such as FAT12 (floppy disks), FAT16 (MS-DOS and early Windows 95 hard disks), and FAT32 (Windows 95B/Windows 98/Me hard disks). You can use Disk Edit with Windows NT, Windows 2000, and Windows XP if you prepared the hard disks with the FAT16 or FAT32 file systems. Disk Edit will also work on NTFS volumes, however in that case it can only be used in physical sector mode.

I strongly recommend that you first use Disk Editor with floppy disks you have prepared with non-critical files before you use it with a hard disk or vital files. Because Disk Editor is a completely manual program, the opportunities for error are high.

The Disk Edit files can easily fit on a floppy disk, but if you are new to the program, you might want to put them on a different drive from one you will be examining or repairing. *Never* copy Disk Edit
files (or any other data recovery program) to a drive that contains data you are trying to recover because the files might overwrite the data area and destroy the files you want to retrieve. For example, if you are planning to examine or repair floppy disks, create a folder on your hard disk called Disk Edit and copy the files to that folder.

You can use Disk Editor without a mouse by using keyboard commands, but if you want to use it with a mouse, you can do so if your mouse attaches to the serial or PS/2 mouse ports (USB mice generally don’t work from the command prompt, but if your USB mouse has a PS/2 mouse port adapter, you can use it by plugging the mouse and adapter into the PS/2 port). You must load an MS-DOS mouse driver (usually MOUSE.COM) for your mouse before you start Disk Editor. If you have a Logitech mouse, you can download an MS-DOS mouse driver from the Logitech Web site. If you have a Microsoft mouse, Microsoft doesn’t provide MS-DOS drivers you can download, but you can get them from the following Web site:

http://www.bootdisk.com/readme.htm#mouse

For other mice, try the Microsoft or Logitech drivers, or contact the vendor for drivers. Keep in mind that scroll wheels and other buttons won’t work with an MS-DOS driver.

I recommend you copy your mouse driver to the same folder in which Disk Editor is located.

Using Disk Editor to Examine a Drive

To start the program, do the following:

1. Boot the computer to a command prompt (not Windows); Disk Editor needs exclusive access to the drives you plan to examine. If you use Windows 9x, press F8 or Ctrl to bring up the startup menu and select Safe Mode Command Prompt, or use the Windows 9x/Me Emergency Startup disk (make one with Add/Remove Programs). If you use Windows 2000 or XP, insert a blank floppy disk into drive A:, right-click drive A: in My Computer, and select Format. Select the Create an MS-DOS Startup Disk option and use this disk to start your computer.

2. Change to the folder containing your mouse driver and Disk Editor.

3. Type MOUSE (if your mouse driver is called MOUSE.COM or MOUSE.EXE; otherwise, substitute the correct name if it’s called something else). Then press Enter to load the mouse driver.

4. Type DISKEDIT and press Enter to start the program. If you don’t specify a drive, Disk Editor scans the drive on which it’s installed. If you are using it to work with a floppy disk, enter the command DISKEDIT A: to direct it to scan your floppy disk. Disk Editor scans your drive to determine the location of files and folders on the disk.

5. The first time you run Disk Editor, a prompt appears to remind you that Disk Editor runs in read-only mode until you change its configuration through the Tools menu. Click OK to continue.

After Disk Editor has started, you can switch to the drive you want to examine or recover data from. To change to a different drive, follow these steps:

1. Press Alt+O to open the Object menu.

2. Select Drive.

3. Select the drive you want to examine from the Logical Disks menu.

4. The disk structure is scanned and displayed in the Disk Editor window.

Disk Editor normally starts in Directory mode, but you can change it to other modes with the View menu. When you view a drive containing data in Directory mode, you will see a listing similar to the one shown in Figure 24.2.
Chapter 24

File Systems and Data Recovery

Figure 24.2  The Norton Disk Editor directory view of a typical floppy disk.

The Name column lists the names of the directory entries, and the .EXT column lists the file/folder extensions (if any). The ID column lists the type of directory entry, including

- **Dir.** A directory (folder).
- **File.** A data file.
- **LFN.** A portion of a Windows long filename. Windows stores the start of the LFN before the actual filename. If the LFN is longer than 13 characters, one or more additional directory entries is used to store the rest of the LFN. The next three columns list the file size, date, and time.

The Cluster column indicates the cluster in which the first portion of the file is located. Drives are divided into clusters or allocation units when they are formatted, and a cluster (allocation unit) is the smallest unit that can be used to store a file. Cluster sizes vary with the size of the drive and the file system used to format the drive.

The letters A, R, S, H, D, and V refer to attributes for each directory entry. A (archive) means the file hasn’t been backed up since it was last modified. R is used to indicate that the directory entry is read-only, and S indicates that the directory entry has the System attribute. H indicates that the directory entry has the Hidden attribute, whereas D indicates that the entry is a directory. Finally, V is the attribute for an LFN entry.

The file VERISI~1.GIF (highlighted in black near the bottom of Figure 24.2) is interesting for several reasons. The tilde (~) and number at the end of the filename indicate that the file was created with a 32-bit version of Windows. 32-bit versions of Windows (Windows 9x/Me, 2000, and XP) allow the user to save a file with a long (more than eight characters) filename (plus the three-character file extension such as .EXE, .BMP, or .GIF). In addition, long filenames can have spaces and other characters not allowed by earlier versions of Windows and MS-DOS. The process used by various versions of Windows to create LFN entries is discussed earlier in this chapter in the section called “VFAT and Long Filenames.”

When you view the file in Windows Explorer or My Computer, you see the long filename. To see the DOS alias name within the Windows GUI, right-click the file and select Properties from My Computer or Windows Explorer. Or, you can use the DIR command in a command-prompt window. The LFN is
stored as one or more separate directory entries just before the DOS alias name. Because the actual long name for `VERISI~1.GIF` (Verisignsealtrans.gif) is 21 characters, two additional directory entries are required to store the long filename (each directory entry can store up to 13 characters of an LFN), as seen in Figure 24.2.

**Determining the Number of Clusters Used by a File**

As discussed earlier in this chapter, an area of the disk called the file allocation table stores the starting location of the file and each additional cluster used to store the file. `VERISI~1.GIF` starts at cluster 632. Clusters are the smallest disk structures used to store files, and they vary in size depending on the file system used to create the disk on which the files are stored and on the size of the drive. In this case, the file is stored on a 1.44MB floppy disk, which has a cluster size of 512 bytes (one sector). The cluster size of the drive is very important to know if you want to retrieve data using Disk Editor.

To determine the cluster size of a drive, you can open a command-prompt window and run `CHKDSK C:` to display the allocation unit size (cluster size) and other statistics about the specified drive. You can also look up the information in Tables 24.10, 24.11, and 24.14 included earlier in this chapter.

To determine how many clusters are used to store a file, look at the size of the file and compare it to the cluster size of the drive on which it's stored. The file `VERISI~1.GIF` contains 6,006 bytes. Because this file is stored on a floppy disk that has a cluster size of 512 bytes, the file must occupy several clusters. How many clusters does it occupy? To determine this, divide the file size by the number of clusters and round the result up to the next whole number. The math is shown in Table 24.36.

**Table 24.36 Determining the Number of Clusters Used by a File**

<table>
<thead>
<tr>
<th>File Size (FS) of VERISI~1.GIF</th>
<th>Cluster Size (CS)</th>
<th>Result of (FS) Divided by (CS) Equals (CR)</th>
<th>(CR) Rounded Up to Next Whole Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>6,006</td>
<td>512</td>
<td>11.73046875</td>
<td>12</td>
</tr>
</tbody>
</table>

From these calculations, you can see that `VERISI~1.GIF` uses 12 clusters on the floppy disk; it would use fewer clusters on a FAT16 or FAT32 hard disk (the exact number depends on the file system and size of the hard disk). The more clusters a file contains, the greater the risk is that some of its data area could be overwritten by newer data if the file is deleted. Consequently, if you need to undelete a file that was not sent to the Windows Recycle Bin or was deleted from a removable-media drive or floppy drive (these types of drives don't support the Recycle Bin), the sooner you attempt to undelete the file, the more likely it is that you can retrieve the data.

The normal directory display in Norton Disk Editor shows the starting cluster (632) for `VERISI~1.GIF`. If a file is stored on a drive with a lot of empty space, the remainder of the clusters will probably immediately follow the first two—a badly fragmented drive might use noncontiguous clusters to store the rest of the file. Because performing data recovery when the clusters are contiguous is much easier, I strongly recommend that you defragment your drives frequently.

To see the remainder of the clusters used by a file, move the cursor to the file, press Alt+L or click the Link menu, and select Cluster Chain (FAT); you can also press Ctrl+T to go directly to this view. The screen changes to show the clusters as listed in the FAT for this file, as shown in Figure 24.3. The clusters used by the file are highlighted in red, and the filename is shown at the bottom of the screen. The symbol `<EOF>` stands for _end of file_, indicating the last cluster in the file.
**How the Operating System Marks a File When It Is Deleted**

If a file (VERISI~1.GIF, in this example) is deleted, the following changes happen to the disk where the file is stored, as shown in Figure 24.4:

- The default directory view shows that the first character of the filename (V) has been replaced with a σ (lowercase sigma) character.
- There are now two new types of entries in the ID column for this file and its associated LFN:
  - *Erased*. An erased file
  - *Del LFN*. An LFN belonging to an erased file

Note also that the beginning cluster (632) is still shown in the Cluster column.

Zeroes have also replaced the entries for the cluster locations after the beginning cluster in the FAT. This indicates to the operating system that these clusters are now available for reuse. Thus, if an undelete process is not started immediately, some or all of the clusters could be overwritten by new data. Because the file in question is a GIF graphics file, the loss of even one cluster will destroy the file.
As you can see from analyzing the file-deletion process, the undelete process involves four steps:

- Restoring the original filename
- Re-creating the FAT entries for the file
- Locating the clusters used by the file
- Relinking the LFN entries for the file to the file

Of these four, the most critical are locating the clusters used by the file and re-creating the FAT entries for the file. However, if the file is a program file, restoring the original name is a must for proper program operation (assuming the program can't be reloaded), and restoring the LFN entries enables a Windows user accustomed to long filenames to more easily use the file.

If you want to make these changes to the original disk, Disk Editor must be configured to work in Read-Write mode.

To change to Read-Write mode, follow these steps:

1. Press Alt+T to open the Tools menu.
2. Press N to open the Configuration dialog box.
3. Press the spacebar to clear the check mark in the Read Only option box.
4. Press the Tab key until the Save box is highlighted.
5. Press Enter to save the changes and return to the main display.

**Caution**

As a precaution, I recommend that you use DISKCOPY to make an exact sector-by-sector copy of a floppy disk before you perform data recovery on it, and you should work with the copy of the disk, not the original. By working with a copy, you keep the original safe from any problems you might have; plus, you can make another copy if you need to.

After you change to Read-Write mode, Disk Editor stays in this mode and uses Read-Write mode every time you use it. To change back to Read-Only mode, repeat the previously listed steps but check the Read-Only box. If you are using Disk Editor in Read-Write mode, you will see the message Drive x is Locked when you scan a drive.

**Undeleting an Erased File**

After you have configured Disk Editor to work in Read-Write mode, you can use it to undelete a file.

To recover an erased file, follow this procedure:

1. To change to the folder containing the erased file, highlight the folder containing the erased file and press Enter. In this example, you will recover the erased file VERISI~1.GIF.
2. Place the cursor under the lowercase sigma symbol and enter the letter you want to use to rename the file.
3. If the keyboard is in Insert mode, the lowercase sigma will move to the right; press the Delete key to delete this symbol.
4. This restores the filename, but even though the ID changes from Erased to File, this does not complete the file-retrieval process. You must now find the rest of the clusters used by the file. To the right of the filename, the first cluster used by the file is listed.
5. To go to the next cluster used by the file, press Ctrl+T to open the Cluster Chain command. Because you changed the name of the file, you are prompted to write the changes to the disk before you can continue. Press W or click Write to save the changes and continue.
6. Disk Editor moves to the first cluster used by the deleted file. Instead of cluster numbers, as seen earlier in Figure 24.3, each cluster contains a zero (0). Because this file uses 12 clusters, there should be 12 contiguous clusters that have been zeroed out if the file is unfragmented.
7. To determine whether these are the correct clusters for the file, press Alt+O or click Object to open the Object menu. Type C to open the Cluster dialog box (or press Alt+C to go to the Cluster dialog box). Enter the starting cluster number (632 in this example) and the ending cluster number (644 in this example). Click OK to display these clusters.

Disk Editor automatically switches to the best view for the specified object, and in this case, the best view is the Hex view (see Figure 24.5). Note that the first entry in cluster 632 is GIF89a (as shown in the right column). Because the deleted file is a GIF file, this is what we expected. Also, a GIF file is a binary graphics file, so the rest of the information in the specified sectors should not be human-readable. Note that the end of the file is indicated by a series of 0s in several disk sectors before another file starts.

8. To return to the FAT to fill in the cluster numbers for the file, open the Object menu and select Directory. The current directory is selected, so click OK.

9. Move the cursor down to the entry for VERISI~1.GIF, open the Link menu, and click Cluster Chain (FAT). The Cluster Chain refers to the clusters after the initial cluster (632); enter 633 in the first empty field, and continue until you enter 643 and place the cursor in the last empty field. This field needs to have the <EOF> marker placed in it to indicate the end of the file. Press Alt+E to open the Edit menu and select Mark (or press Ctrl+B). Open the Edit menu again and select Fill. Then, select End of File from the menu and click OK. Refer to Figure 24.3 to see how the FAT looks after these changes have been made.

10. To save the changes to the FAT, open the Edit menu again and select Write. When prompted to save the changes, click Write; then click Rescan the Disk.
11. To return to Directory view, open the Object menu and select Directory. Click OK.

12. The LFN entries directly above the VERISI~1.GIF file are still listed as Del LFN. To reconnect them to VERISI~1.GIF, select the first one (verisignsealt), open the Tools menu (press Alt+T), and select Attach LFN. Click Yes when prompted. Repeat the process for rans.gif.

13. To verify that the file has been undeleted successfully, exit Disk Editor and open the file in a compatible program. If you have correctly located the clusters and linked them, the file will open.

As you can see, this is a long process, but it is essentially the same process that a program such as Norton UnErase performs automatically. However, Disk Editor can perform these tasks on all types of disks that use FAT file systems, including those that use non-DOS operating systems; it’s a favorite of advanced Linux users.

**Retrieving a File from a Hard Disk or Flash Memory Card**

What should you do if you need to retrieve an erased file from the hard disk or a flash memory card? It’s safer to write the retrieved file to another disk (preferably a floppy disk if the file is small enough) or to a different drive letter on the hard disk. You can also perform this task with Disk Editor.

**Tip**

If you want to recover data from a hard disk and copy the data to another location, set Disk Editor back to its default Read-Only mode to avoid making any accidental changes to the hard disk. If you use Disk Editor in a multitasking environment such as Windows, it defaults to Read-Only mode.

The process of locating the file is the same as that described earlier:

1. Determine the cluster (allocation unit) size of the drive on which the file is located.
2. Run Disk Editor to view the name of the erased file and determine which clusters contain the file data.

However, you don’t need to restore the filename because you will be copying the file to another drive. The clusters will be copied to another file, so it’s helpful to use the Object menu to look at the clusters and ensure that they contain the necessary data. To view the data stored in the cluster range, open the Object menu, select Cluster, and enter the range of clusters that the cluster chain command indicates should contain the data. In some cases, the first cluster of a particular file indicates the file type. For example, a GIF file has GIF89a at the start of the file, whereas a WordPerfect document has WPC at the start of the file.

**Tip**

Use Norton Disk Editor to view the starting and ending clusters of various types of files you create before you try to recover those types of files. This is particularly important if you want to recover files from formatted media. You might consider creating a database of the hex characters found at the beginning and ending of the major file types you want to recover.

If you are trying to recover a file that contains text, such as a Microsoft Word or WordPerfect file, you can switch Disk Edit into different view modes. To see text, press F3 to switch to Text view. However, to determine where a file starts or ends, use Hex mode (press F2 to switch to this mode). Figure 24.6 shows the start of a Microsoft Word file in Text format and the end of the file in Hex format.
To copy the contents of these clusters to a file safely, you should specify the sectors that contain the file. The top of the Disk Editor display shows the sector number as well as the cluster number. For example, the file shown in Figure 24.6 starts at cluster 75207, which is also sector 608470. The end of the file is located in sector 608503.

To write these sectors to a new file, do the following:

1. Open the Object menu.
2. Select Sector.
3. Specify the starting and ending sectors.
4. Click OK.
5. Scroll through the sectors to verify that they contain the correct data.
6. Open the Tools menu.
7. Click Write Object to.
8. Click To a File.
9. Click the drive on which you want to write the data.
10. Specify a DOS-type filename (8 characters plus a 3-character extension); you can rename the file to a long filename after you exit Disk Edit.
11. Click OK, and then click Yes to write the file. A status bar appears as the sectors are copied to the file.
12. Exit Disk Edit and open the file in a compatible program. If the file contains the correct data, you’re finished. If not, you might have specified incorrect sectors or the file might be fragmented.

Norton Disk Editor is a powerful tool you can use to explore drives and retrieve lost data. However, your best data recovery technique is to avoid the need for data recovery. Think before you delete files or format a drive, and make backups of important files. That way, you won’t need to recover lost data very often.
Data Recovery from Flash Memory Devices

Flash memory devices such as USB keychain drives and cards used in digital cameras and digital music players present a unique challenge to data recovery programs. Although, from a user standpoint, these devices emulate conventional disk drives, have file allocation tables similar to those found on floppy disks, and can usually be formatted through the Windows Explorer, many data recovery programs that work well with conventional drives cannot be used to recover data from flash memory devices—especially when the device has been formatted.

Under several conditions, data loss can occur with a flash memory device. Some of them, such as formatting of the media or deletion of one or more photos or files, can occur when the device is connected to the computer through a card reader or when the flash memory device is inserted into a digital camera. When photos are deleted, the file locations and name listings in the file allocation tables are changed in the same way as when files are deleted from magnetic media: The first character of the filename is changed to a lowercase sigma (refer to Table 24.19), indicating the file has been erased. Just as with magnetic media, undelete programs that support removable-media drives and the Norton Disk Editor can be used to retrieve deleted files on flash memory devices in the same way that they retrieve deleted files from magnetic media. Note that Disk Editor must be run in read-only mode and works best on systems running Windows 9x/Me. Data files can also be damaged if the flash memory card is removed from a device before the data-writing process is complete.

However, retrieving data from a formatted flash memory device, whether it has been formatted by a digital camera or through Windows, is much more difficult. Traditional unformat programs such as the command-line Norton Unformat program provided with Norton Utilities and Norton SystemWorks can’t be used because flash memory devices are accessible only from within the Windows GUI and command-line programs are designed to work with BIOS-compatible devices such as hard and floppy drives.

Programs that rely on the file system, such as Ontrack EasyRecovery Personal Edition Lite (incorporated into VCOM System’s Suite) and Ontrack EasyRecovery Personal Edition, do not work either because the previous file system is destroyed when the flash memory devices are formatted.

Note

When a digital camera formats a flash memory card, it usually creates a folder in which photos are stored. Some cameras might also create another folder for storing drivers or other information.

If you need to recover data from a formatted flash memory device, the following programs work extremely well:

- **Ontrack EasyRecovery Professional Edition;** free evaluation and more information are available from http://www.ontrack.com
- **PhotoRescue;** free evaluation and more information are available from http://www.datarescue.com/photorescue/

Norton Disk Editor (incorporated into Norton SystemWorks, and Norton SystemWorks Pro) can also be used to recover data if you can determine the starting and ending clusters used by the data stored on the device.

To recover data from a formatted flash memory card with EasyRecovery Professional Edition, the RawRecovery option (which recovers data on a sector-by-sector basis) must be used. This option bypasses the file system and can be used on all supported media types. A built-in file viewer enables you to determine whether the recovered data is readable.

PhotoRescue, which works only with standard photo image types such as JPG, BMP, and TIF, can access the media in either logical drive mode (which worked quite well in our tests) or physical drive mode. Physical mode uses a sector-by-sector recovery method somewhat similar to that used by EasyRecovery Professional Edition. PhotoRescue also displays recovered photos in a built-in viewer.
With both products, you might recover data from not just the most recent use before format, but also leftover data from previous uses. As long as the data area used by a particular file hasn’t been overwritten, the data can be recovered—even if the device has been formatted more than once.

Table 24.37 provides an overview of our results when trying to recover data from two common types of flash memory devices: a Compact Flash card used in digital cameras and a USB keychain storage device.

### Table 24.37 Retrieving Lost Data from Flash Memory Devices

<table>

</tbody>
</table>

1. User supplied first letter of filename during undelete process.
2. Norton UnErase doesn’t support removable-media drives in Windows NT/2000/XP.
3. Program operates in read-only mode on the drive containing the lost data.
4. Original file and folder names were not retained; files are numbered sequentially and might need to be renamed after recovery.
5. Windows must be used to access flash memory devices, and Norton Unformat can’t be used in a multitasking environment such as Windows.
6. Disk Edit requires the user to manually locate the starting and ending sectors of each file and write the sectors to another drive with a user-defined filename.
Common Drive Error Messages and Solutions

Several common error messages are associated with problems in the file system or drives. This section covers the common ones, listing their causes and possible solutions.

Some of the most common file system errors are as follows:

- Missing Operating System
- NO ROM BASIC - SYSTEM HALTED
- Boot Error Press F1 to Retry
- Invalid Drive Specification
- Invalid Media Type
- Hard Disk Controller Failure

These usually occur when booting the system or when trying to log in to or access a drive. The following sections describe each of these errors and offer possible solutions.

Missing Operating System

This error indicates problems in the master boot record or partition table entries. The partition table entries might be pointing to a sector that is not the actual beginning of a partition. This can also be caused by invalid BIOS settings, in some cases resulting from a dead or dying battery. In fact, in my experience, corrupt or improper BIOS settings—such as incorrect geometry (cylinder/head/sector) or LBA mode settings—are the leading cause of this problem. Another cause can be virus damage to the MBR. This error also can occur if no active partition is defined in the partition table.

The normal solution is to correct the invalid BIOS settings. The BIOS settings for drive parameters and LBA translation must be set to the same values as when the drive was partitioned and formatted to read the drive correctly. If the MBR on a FAT drive is damaged or virus infected, you can try FDISK /MBR to repair it. Use FIXMBR with an NTFS drive. Other types of damage require more sophisticated use of a disk editor utility or repartitioning and reformatting the drive to start over.

NO ROM BASIC - SYSTEM HALTED

This error is generated by the AMI BIOS when the boot sector or master boot record of the boot drive is damaged or missing. This error also can occur if the boot device has been improperly configured or is not configured at all in the BIOS. In this case, data in the partition might be valid and undamaged, but no bootable partition exists.

IBM systems in this situation used to drop into a built-in BIOS version of BASIC, but most non-IBM BIOS manufacturers did not license this code from Microsoft. So, instead of dropping into BASIC, they displayed this cryptic message. Because the most common cause of this type of error is a failure to set at least one partition as active (bootable), the typical solution is to run FDISK and set the primary partition as active. If this is not the problem, the solution is to repair the damaged MBR or correct the improper BIOS settings.

Other possible problems include corrupted or missing drive parameters in the BIOS Setup.

Boot Error Press F1 to Retry

This error is generated by the Phoenix BIOS when the hard disk is missing a master boot record or boot sector or when there is a problem accessing the boot drive. This has the same meaning as NO ROM BASIC does on an AMI BIOS. The most common cause of this message is having no partitions defined as active (bootable). See the previous section for more information.

Invalid Drive Specification

This error occurs when you attempt to log in to a drive that has not been partitioned or for which the partition table entry has been damaged or is incorrect. Use FDISK to partition the drive or to check out the existing partitions. If they are damaged, you probably should use a data recovery utility such as the Norton Utilities to correct the problem. Such correction might require manual editing of the
partition table with the Disk Edit program included with the Norton Utilities. Another solution is to repartition the drive from scratch, but this causes any existing data on the drive to be overwritten.

**Invalid Media Type**

This indicates the partition table is valid, but the volume boot sector, directory, or file allocation tables are corrupt, damaged, or not yet initialized. For example, this is the standard error you would receive if you tried to access a drive that had been partitioned but not yet formatted. The `FORMAT` command is what creates the volume boot record (VBR), file allocation tables, and directories on the disk.

The repair typically involves using a data recovery utility, such as the Norton Utilities Disk Doctor, or redoing the high-level format on the drive. Because high-level formatting does not actually destroy the data, one technique to recover is to high-level format (OS Format) the volume and then immediately unformat it using the unformat utility included with the Norton Utilities.

**Hard Disk Controller Failure**

This message indicates the hard disk controller has failed, the hard disk controller is not set up properly in the BIOS, or the controller can’t communicate with the attached drives (such as with cable problems).

The solution is to check out the drive installation and ensure that the cables to the drive are properly installed, the drive is receiving power, it is spinning, and the BIOS Setup definitions are correct. If all these are correct, the drive, cable, or controller might be physically damaged. Replace them with known-good spares one at a time until the problem is solved.

**General File System Troubleshooting for MS-DOS, Windows 9x, and Windows Me**

Here are some general procedures to follow for troubleshooting drive access, file system, or boot problems:

1. Start the system using a Windows startup disk, or any bootable MS-DOS disk that contains `FDISK.EXE`, `FORMAT.COM`, `SYS.COM`, and `SCANDISK.EXE` (Windows 95B or later versions preferred).

2. If your system can’t boot from the floppy, you might have more serious problems with your hardware. Check the floppy drive and the motherboard for proper installation and configuration. On some systems, the BIOS configuration doesn’t list the floppy as a boot device or puts it after the hard disk. Reset the BIOS configuration to make the floppy disk the first boot device if necessary and restart your computer.

3. Run `FDISK` from the Windows startup disk. Select option 4 (Display partition information).

4. If the partitions are listed, make sure that the bootable partition (usually the primary partition) is defined as active (look for an uppercase A in the Status column).

5. If no partitions are listed and you do not want to recover any of the data existing on the drive now, use `FDISK` to create new partitions, and then use `FORMAT` to format the partitions. This overwrites any previously existing data on the drive.

6. If you want to recover the data on the drive and no partitions are being shown, you must use a data recovery program, such as the Norton Utilities by Symantec or Lost and Found by PowerQuest, to recover the data.

7. If all the partitions appear in `FDISK.EXE` and one is defined as active, run the `SYS` command as follows to restore the system files to the hard disk:

   ```
   SYS C:
   ```

8. For this to work properly, it is important that the disk you boot from be a startup disk from the same operating system (or version of Windows) you have on your hard disk.
9. You should receive the message System Transferred if the command works properly. Remove the disk from drive A:, and restart the system. If you still have the same error after you restart your computer, your drive might be improperly configured or damaged.

10. Run SCANDISK from the Windows startup disk or an aftermarket data-recovery utility, such as the Norton Utilities, to check for problems with the hard disk.

11. Using SCANDISK, perform a surface scan. If SCANDISK reports any physically damaged sectors on the hard disk, the drive might need to be replaced.

**General File System Troubleshooting for Windows 2000/XP**

The process for file system troubleshooting with Windows 2000/XP is similar to that used for Windows 9x. The major difference is the use of the Windows 2000/XP Recovery Console, which is clarified here:

- If the Recovery Console was added to the boot menu, start the system normally, log in as Administrator if prompted, and select the Recovery Console.
- If the Recovery Console was not previously added to the boot menu, start the system using the Windows CD-ROM or the Windows Setup disks. Select Repair from the Welcome to Setup menu, and then press C to start the Recovery Console when prompted.

If your system can’t boot from CD-ROM or the floppy, you might have more serious problems with your hardware. Check your drives, BIOS configuration, and motherboard for proper installation and configuration. Set the floppy disk as the first boot device and the CD-ROM as the second boot device and restart the system.

After you start the Recovery Console do the following:

1. Type HELP for a list of Recovery Console commands and assistance.
2. Run DISKPART to examine your disk partitions.
3. If the partitions are listed, make sure that the bootable partition (usually the primary partition) is defined as active.
4. If no partitions are listed and you do not want to recover any of the data existing on the drive now, use FDISK to create new partitions, and then use FORMAT to format the partitions. This overwrites any previously existing data on the drive.
5. If you want to recover the data on the drive and no partitions are being shown, you must use a data recovery program, such as the Norton Utilities by Symantec or Lost and Found by PowerQuest, to recover the data.
6. If all the partitions appear in DISKPART and one is defined as active, run the FIXBOOT command as follows to restore the system files to the hard disk:
   
   FIXBOOT

7. Type EXIT to restart your system. Remove the disk from drive A: or the Windows 2000 or XP CD-ROM from the CD-ROM drive.
8. If you still have the same error after you restart your computer, your drive might be improperly configured or damaged.
9. Restart the Recovery Console and run CHKDSK to check for problems with the hard disk.
Glossary

This glossary contains computer and electronics terms that are applicable to the subject matter in this book. The glossary is meant to be as comprehensive as possible on the subject of upgrading and repairing PCs. Many terms correspond to the latest technology in disk interfaces, modems, video and display equipment, and standards that govern the PC industry. Although a glossary is a resource not designed to be read from beginning to end, you should find that scanning through this one is interesting, if not enlightening, with respect to some of the newer PC technology.

The computer industry is filled with abbreviations used as shorthand for a number of terms. This glossary defines many abbreviations, as well as the terms on which the abbreviations are based. The definition of an abbreviation usually is included under the acronym. For example, video graphics array is defined under the abbreviation VGA rather than under video graphics array. This organization makes looking up a term easier—IDE, for example—even if you do not know in advance what it stands for (integrated drive electronics).

For additional reference, Que's Computer Dictionary (ISBN: 0-7897-1670-4) is a comprehensive dictionary of computer terminology.

These Web sites can also help you with terms not included in this glossary:

webservices.cnet.com/cgi/Glossary.asp
www.webopedia.com
whatis.techtarget.com
1–50X CD-ROM maximum speeds in relation to the speed of a music CD (1X = 150Kbps). At speeds of 16X or above, most drives are CAV and reach their rated speeds only on the outer edges of the disc. See also CLV and CAV.

3GIO The original name for PCI Express, a forthcoming replacement for existing PCI connections. See also PCI Express.

10BASE-2 IEEE standard for baseband Ethernet at 10Mbps over RG-58 coaxial cable to a maximum distance of 185 meters. Also known as Thin Ethernet (Thinnet) or IEEE 802.3.

10BASE-5 IEEE standard for baseband Ethernet at 10Mbps over thick coaxial cable to a maximum distance of 500 meters. Also known as Thick Ethernet or Thicknet.

10BASE-T A 10Mbps CSMA/CD Ethernet LAN that works on Category 3 or better twisted-pair wiring, which is very similar to standard telephone cabling. 10BASE-T Ethernet LANs work on a “star” configuration, in which the wire from each workstation routes directly to a 10BASE-T hub. Hubs can be joined together. 10BASE-T has a maximum distance of 100 meters between each workstation and the hub.

24x7 Refers to continuous 24 hours a day, 7 days a week computer or services operation.

56K The generic term for modems that can receive data at a maximum rate of 56Kbps. See also V.90, V.92, X2, K56flex.

64-bit processor A processor that has 64-bit registers. The Intel Itanium and Itanium 2 processors for workstations and servers, which can also emulate 32-bit Intel processors; the AMD Athlon 64 desktop processor, which also emulates 32-bit x86 Intel and AMD processors; and the AMD Opteron, designed for use in server and workstation tasks, are some of the 64-bit processors now available.

100BASE-T A 100Mbps CSMA/CD Ethernet local area network (LAN) that works on Category 5 twisted-pair wiring. 100BASE-T Ethernet LANs work on a “star” configuration in which the wire from each workstation routes directly to a central 100BASE-T hub. This is the current standard for 100Mbps Ethernet, replacing 100BASE-VG.

100BASE-VG The joint Hewlett-Packard–AT&T proposal for Fast Ethernet running at 100Mbps. It uses four pairs of Category 5 cable using the 10BASE-T twisted-pair wiring scheme to transmit or receive. 100BASE-VG splits the signal across the four wire pairs at 25MHz each. This standard has not found favor with corporations and has been almost totally replaced by 100BASE-T.

286 See 80286.

386 See 80386DX.

404 Web site error code indicating the specified page is not found. Some Web sites display a customized error message instead of the standard 404 code.

486 See 80486DX.

586 A generic term used to refer to fifth-generation processors similar to the Intel Pentium, such as the AMD K6 series and the VIA Cyrix MIL.

640KB barrier The limit imposed by the PC-compatible memory model using DOS mode. DOS programs can address only 1MB total memory, and PC-compatibility generally requires the top 384KB to be reserved for the system, leaving only the lower 640KB for DOS or other real-mode applications.

802.11 The family name for various wireless Ethernet standards. See also IEEE 802.11 family.

1000BASE-T A 1,000Mbps Ethernet local area network (LAN) that runs over four pairs of Category 5 cable. Popularly known as Gigabit Ethernet, 1000BASE-T can be used as an upgrade to a properly wired 100BASE-T network because the same cable and distance limitations (100 meters) apply.

1394 See FireWire.

8086 An Intel microprocessor with 16-bit registers, a 16-bit data bus, and a 20-bit address bus. This processor can operate only in real mode.

8087 An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 8087 can be installed in most 8086- and 8088-based systems and adds more than 50 new instructions to those available in the primary CPU alone.

8088 An Intel microprocessor with 16-bit registers, an 8-bit data bus, and a 20-bit address bus. This processor can operate only in real mode and was designed as a low-cost version of the 8086.

8514/A An analog video display adapter from IBM for the PS/2 line of personal computers. Compared to previous display adapters, such as EGA and VGA, it provides a high resolution of 1,024×768 pixels with as many as 256 colors or 64 shades of gray. It provides a video coprocessor that performs two-dimensional graphics functions internally, thus relieving the CPU of graphics tasks. It uses an interlaced monitor and scans every other line every time the screen is refreshed.

80286 An Intel microprocessor with 16-bit registers, a 16-bit data bus, and a 24-bit address bus. It can operate in both real and protected virtual modes.

80287 An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 80287 can be installed in most 286- and some 386DX-based systems, and it adds more than 50 new instructions to what is available in the primary CPU alone.
80386  See 80386DX.

80386DX  An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. This processor can operate in real, protected, virtual, and virtual real modes.

80386SX  An Intel microprocessor with 32-bit registers, a 16-bit data bus, and a 24-bit address bus. This processor, designed as a low-cost version of the 386DX, can operate in real, protected virtual, and virtual real modes.

80387DX  An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 80387DX can be installed in most 386DX-based systems and adds more than 50 new instructions to those available in the primary CPU alone.

80387SX  An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 80387SX can be installed in most 386SX-based systems and adds more than 50 new instructions to those available in the primary CPU alone.

80486  See 80486DX.

80486DX  An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. The 486DX has a built-in cache controller with 8KB of cache memory as well as a built-in math coprocessor equivalent to a 387DX. The 486DX can operate in real, protected virtual, and virtual real modes.

80486DX2  A version of the 486DX with an internal clock-doubling circuit that causes the chip to run at twice the motherboard clock speed. If the motherboard clock is 33MHz, the DX2 chip will run at 66MHz. The DX2 designation applies to chips sold through the OEM market, whereas a retail version of the DX2 sold by Intel and designed for use as an upgrade was sold as an Overdrive processor.

80486DX4  A version of the 486DX with an internal clock-tripling circuit that causes the chip to run at three times the motherboard clock speed. If the motherboard clock is 33.33MHz, the DX4 chip will run at 100MHz.

80486SX  An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. The 486SX is the same as the 486DX, except that it lacks the built-in math coprocessor function and was designed as a low-cost version of the 486DX. The 486SX can operate in real, protected virtual, and virtual real modes.

80487SX  An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. Although the name implies that the 80487SX adds floating-point math capabilities, in reality the 487SX is the same as the 486DX, except that it uses a modified pinout and must be installed in a special 80487SX socket. When installed, the 80487SX replaces the 80486SX for all processing tasks. The 487SX can operate in real, protected virtual, and virtual real modes.

A+  Refers to the ComptIA A+ Certification, a vendor-neutral certification for computer hardware technicians. A+ Certification exams test knowledge of basic hardware and software skills. The A+ Certification can be used as part of the exam requirements for the Microsoft Certified System Administrator (MCSA) credential.

abend  Short for abnormal end. A condition occurring when the execution of a program or task is terminated unexpectedly because of a bug or crash.

absolute address  An explicit identification of a memory location, device, or location within a device.

AC (alternating current)  The frequency is measured in cycles per seconds (cps) or hertz (Hz). The standard value running through the wall outlet is 120 volts at 60Hz through a fuse or circuit breaker that usually can handle about 15 or 20 amps.

accelerated graphics port  See AGP.

Accelerated Hub Architecture (AHA)  An Intel technology used on its 800-series chipsets to transfer data between the memory controller hub (MCH), which is equivalent to the North Bridge, and the input/output controller hub (ICH), which is equivalent to the South Bridge. AHA transfers data at 266MBps, twice the speed of the PCI bus previously used.

accelerator board  An add-in board replacing the computer's CPU with circuitry that enables the system to run more quickly. See also graphics accelerator.

access light  The LED on the front of a drive or other device (or on the front panel of the system) that indicates the computer is reading or writing data on the device.

access mechanism  See actuator.

access time  The time that elapses from the instant information is requested to the point that delivery is completed. It's usually described in picoseconds (ps) for memory chips and in milliseconds (ms) for disk drives. Most manufacturers rate average access time on a hard disk as the time required for a seek across one third of the total number of cylinders plus one-half the time for a single revolution of the disk platters (latency).

accumulator  A register (temporary storage) in which the result of an operation is formed.

acoustic coupler  A device used to connect a computer modem to a phone line by connecting to the handset of a standard AT&T-style phone. The audible sounds to and from the modem are transmitted to the handset through the coupler while the handset is resting in the coupler. Although often thought of as obsolete, an acoustic coupler can be used to ensure the availability of a modem connection when traveling and access to an RJ-11 jack is unavailable.

ACPI (Advanced Configuration and Power Interface)  A standard developed by Intel, Microsoft, and Toshiba that is designed to implement power management functions in the operating system. ACPI is a replacement for APM. See also APM.
ACR  Short for Advanced Communication Riser, an alternative to CNR advocated by the ACR Special Interest Group (www.acrsig.org). ACR, like CNR, is designed to allow motherboard designers to add low-cost network capabilities to motherboards but uses the same PCI connector used by PCI expansion cards.

Adobe Acrobat  Refers to the Adobe Acrobat program for creating and reading cross-platform documents created in Adobe's Portable Document Format (PDF) file format. Many computer and component manuals are available online in Acrobat format. The Acrobat Reader can be downloaded free from Adobe’s Web site.

active high  Designates a digital signal that must go to a high value to be true. Synonymous with positive.

active low  Designates a digital signal that must go to a low value to be true. Synonymous with negative.

active matrix  A type of LCD screen that contains at least one transistor for every pixel on the screen. Color active-matrix screens use three transistors for each pixel—one each for the red, green, and blue dots. The transistors are arranged on a grid of conductive material, with each connected to a horizontal and a vertical member. See also TFT.

active partition  Any partition marked as bootable in the partition table. See also boot manager.

actuator  The device that moves a disk drive's read/write heads across the platter surfaces. Also known as an access mechanism.

adapter  The device that serves as an interface between the system unit and the devices attached to it. It's often synonymous with circuit board, circuit card, or card, but it also can refer to a connector or cable adapter that changes one type of connector to another.

adapter description files (ADF)  Refers to the setup and configuration files and drivers necessary to install an adapter card, such as a network adapter card. Primarily used with Micro Channel Architecture (MCA) bus cards.

add-in board  See expansion card.

address  Refers to where a particular piece of data or other information is found in the computer. Also can refer to the location of a set of instructions.

address bus  One or more electrical conductors used to carry the binary-coded address from the microprocessor throughout the rest of the system.

ADSL (asymmetric digital subscriber line)  A high-speed transmission technology originally developed by Bellcore and now standardized by ANSI as T1.413. ADSL uses existing UTP copper wires to communicate digitally at high speed between the telephone company central office (CO) and the subscriber. ADSL sends information asymmetrically, meaning it is faster one way than the other. The original ADSL speed was T-1 (1.536Mbps) downstream from the carrier to the subscriber’s premises and 16Kbps upstream. However, ADSL is available in a variety of configurations and speeds. See also DSL.

AGP (accelerated graphics port)  Developed by Intel, AGP is a fast, dedicated interface between the video adapter or chipset and the motherboard chipset North Bridge. AGP is 32 bits wide; runs at 66MHz base speed; and can transfer 1, 2, 4, or 8 bits per cycle (1x, 2x, 4x, or 8x modes) for a throughput of up to 2132MBps.

aliasing  Undesirable visual effects (sometimes called artifacts) in computer-generated images caused by inadequate sampling techniques. The most common effect is jagged edges along diagonal or curved object boundaries. See also antialiasing.

allocation unit  See cluster.

alphanumeric characters  A character set that contains only letters (A–Z) and digits (0–9). Other characters, such as punctuation marks, also might be allowed.

AMD  Short for Advanced Micro Devices, the number-two PC processor maker. AMD makes the popular K6, Athlon, Opteron, and Duron series of processors, as well as chipsets and flash memory devices.

amperes  The basic unit for measuring electrical current. Also called amp.

AMR  Short for Audio/Modem Riser, it's an Intel-developed specification for packaging modem I/O ports and a codec chip into a small card that can be installed into an AMR slot on a motherboard. Although many motherboards have AMR slots, AMR risers have not been popular, and the CNR specification has largely replaced AMR. See also CNR.

analog  The representation of numerical values by physical variables such as voltage, current, and so on; continuously variable quantities whose values correspond to the quantitative magnitude of the variables.

analog loopback  A modem self-test in which data from the keyboard is sent to the modem’s transmitter, modulated into analog form, looped back to the receiver, demodulated into digital form, and returned to the screen for verification.

analog signals  Continuously variable signals. Analog circuits are more subject to distortion and noise than are digital circuits but are capable of handling complex signals with relatively simple circuitry. See also digital signals.

analog-to-digital converter  An electronic device that converts analog signals to digital form.

AND  A logic operator having the property that if P is a statement, Q is a statement, R is a statement..., then the AND of P, Q, R... is true if all statements are true and is false if any statement is false.

AND gate  A logic gate in which the output is 1 only if all inputs are 1.

animation  The process of displaying a sequential series of still images to achieve a motion effect.
ANSI (American National Standards Institute)  
A nongovernmental organization founded in 1918 to propose, modify, approve, and publish data processing standards for voluntary use in the United States. It’s also the U.S. representative to the International Standards Organization (ISO) in Paris and the International Electrotechnical Commission (IEC). For more information, see the Vendor List on the DVD. Contact ANSI, 1430 Broadway, New York, NY 10018.

answer mode  A state in which the modem transmits at the predefined high frequency of the communications channel and receives at the low frequency. The transmit/receive frequencies are the reverse of the calling modem, which is in originate mode. See also originate mode.

antialiasing  Software adjustment to make diagonal or curved lines appear smooth and continuous in computer-generated images. See also aliasing.

antistatic mat  A pad placed next to a computer upon which components are placed while servicing the system to prevent static damage. Also can refer to a larger-sized mat below an entire computer desk and chair to discharge static from a user before he touches the computer.

antivirus  Software that prevents files containing viruses from running on a computer or software that detects, repairs, cleans, or removes virus-infected files.

APA (all points addressable)  A mode in which all points of a displayable image can be controlled by the user or a program.

aperture grille  A type of shadow mask used in CRTs. The most common is used in Sony’s Trinitron monitors, which use vertical phosphor stripes and vertical slots in the mask, compared to the traditional shadow mask that uses phosphor dots and round holes in the mask. See also shadow mask.

API (application program interface)  A system call (routine) that gives programmers access to the services provided by the operating system. In IBM-compatible systems, the ROM BIOS and DOS together present an API that a programmer can use to control the system hardware.

APM (Advanced Power Management)  A specification sponsored by Intel and Microsoft originally proposed to extend the life of batteries in battery-powered computers. It is now used in desktop computers as well. APM enables application programs, the system BIOS, and the hardware to work together to reduce power consumption. An APM-compliant BIOS provides built-in power-management services to the operating system. The application software communicates power-saving data via predefined APM interfaces. Replaced in newer systems by ACPI. See also ACPI.

application  End-user-oriented software, such as a word processor, spreadsheet, database, graphics editor, game, or Web browser.

Application Layer  See OSI.

arbitration  A method by which multiple devices attached to a single bus can bid or arbitrate to get control of that bus.

archive bit  The bit in a file’s attribute byte that sets the archive attribute. Tells whether the file has been changed since it last was backed up.

archive file  A collection of files that has been stored (often in a compressed format) within a single file. Zip and CAB files are the most common types of archive file formats used with Windows-based PCs. See also Zip file and CAB file.

archive medium  A storage medium (floppy disk, tape cartridge, or removable cartridge) to hold files that need not be accessible instantly.

ARCnet (Attached Resource Computer Network)  A baseband, token-passing LAN technology offering a flexible bus/star topology for connecting personal computers. Operating at 2.5Mbps, it is one of the oldest LAN systems and was popular in low-cost networks. It was originally developed by John Murphy of Datapoint Corporation. Although ARCnet (www.arcnet.com) is no longer used for office networking, it is still a popular choice for networking embedded systems, such as heating and air conditioning systems.

areal density  A calculation of the bit density (bits per inch, or BPI) multiplied by the track density (tracks per inch, or TPI), which results in a figure indicating how many bits per square inch are present on the disk surface.

ARQ (automatic repeat request)  A general term for error-control protocols that feature error detection and automatic retransmission of defective blocks of data.

ASCII (American Standard Code for Information Interchange)  A standard 7-bit code created in 1965 by Robert W. Bemer to achieve compatibility among various types of data processing equipment. The standard ASCII character set consists of 128 decimal numbers ranging from 0 to 127, which are assigned to letters, numbers, punctuation marks, and the most common special characters. In 1981, IBM introduced the extended ASCII character set with the IBM PC, extending the code to 8 bits and adding characters from 128 to 255 to represent additional special mathematical, graphics, and foreign characters.

ASCII character  A 1-byte character from the ASCII character set, including alphabetic and numeric characters, punctuation symbols, and various graphics characters.

ASME (American Society of Mechanical Engineers; www.asme.org)  ASME International has nearly 600 codes and standards in print, and its many committees involve more than 3,000 individuals, mostly engineers but not necessarily members of the society. The standards are used in more than 90 countries throughout the world.
aspect ratio  The measurement of a film or television viewing area in terms of relative height and width. The aspect ratio of most modern motion pictures varies from 5:3 to as large as 16:9, which creates a problem when a wide-format motion picture is transferred to the more square-shaped television screen or monitor, with its aspect ratio of 4:3. See also letterbox.

assemble  The act of translating a program expressed in an assembler language into a computer machine language.

assembler language  A computer-oriented language whose instructions are usually in one-to-one correspondence with machine language instructions.

asymmetrical modulation  A duplex transmission technique that splits the communications channel into one high-speed channel and one slower channel. During a call under asymmetrical modulation, the modem with the greater amount of data to transmit is allocated the high-speed channel. The modem with less data is allocated the slow, or back, channel. The modems dynamically reverse the channels during a call if the volume of data transfer changes.

asynchronous communication  Data transmission in which the length of time between transmitted characters can vary. Timing depends on the actual time for the transfer to take place, as opposed to synchronous communication, which is timed rigidly by an external clock signal. Because the receiving modem must be signaled about when the data bits of a character begin and end, start and stop bits are added to each character. See also synchronous communication.

asynchronous memory  Memory that runs using a timing or clock rate different from (usually slower than) the motherboard speed.

AT clock  Refers to the Motorola 146818 real-time clock (RTC) and CMOS RAM chip, which first debuted in the IBM AT and whose function has been present in all PC-compatible systems since. Keeps track of the time of day and makes this data available to the operating system or other software.

ATA (AT Attachment Interface)  An IDE disk interface standard introduced in March 1989 that defines a compatible register set, a 40-pin connector, and its associated signals. See also IDE and SATA.

ATA-2  The second-generation AT Attachment Interface specification, approved in 1996. This version defines faster transfer modes and logical block addressing schemes to allow high-performance, large-capacity drives. Also called Fast ATA, Fast ATA-2, and enhanced IDE (EIDE).

ATA-3  Published in 1997, ATA-3 defines 8-bit DMA transfers and SMART support for drive failure prediction.

ATA/ATAPI-4  The fourth-generation ATA specification was published in 1998. ATA/ATAPI-4 incorporates ATAPI and adds Ultra DMA/33 (33MBps) transfer mode; APM support; an optional 80-wire, 40-pin cable; support for Compact Flash memory devices; and enhanced BIOS support for larger drives.

ATA/ATAPI-5  Approved in 2000, ATA/ATAPI-5 includes UDMA/66 support, mandates the 80-wire cable for UDMA/66, detects the cable type, and allows UDMA/66 or faster speeds only if the 80-wire cable is present.

ATA/ATAPI-6  The latest draft standard, ATA/ATAPI-6 includes UDMA/100 (100MBps) support and increases the ATA drive size limit to 144.12PB (petabytes). See also petabyte.

ATAPI (AT Attachment Packet Interface)  A specification that defines device-side characteristics for an IDE-connected peripheral, such as a CD-ROM or tape drive. ATAPI is essentially an adaptation of the SCSI command set to the IDE interface. ATA-4 and newer ATA standards include ATAPI standards.

Athlon  An AMD sixth-generation processor family roughly comparable to the Intel Pentium III and Pentium 4. Later models (beginning with the Thunderbird core) include on-die L2 cache running at full core speed. It includes MMX and AMD 3DNow! instructions for multimedia performance. Originally available in a Slot-A cartridge package, all Athlons are now available only in the Socket-A (462-pin) package. The Mobile Athlon XP, which replaced the Athlon 4, is designed for mobile applications, the Athlon MP is designed for workstation/server multiprocessor configurations, and the Athlon XP is designed mainly for single processor applications. All three use the improved Thoroughbred core and 3DNow! Professional multimedia extensions. The Athlon XP processors include AMD’s new QuantiSpeed design for faster internal operation and are rated by their performances relative to the Intel Pentium 4, rather than by their clock speeds. For example, the Athlon XP 2600+, which performs comparably to the Pentium 4 2.6GHz processor, runs at a clock speed of about 2.1GHz.

Athlon 64  An AMD processor (code-named Clawhammer) that uses a 64-bit internal design. The Athlon 64 also emulates 32-bit x86 processors from Intel and AMD. It uses a new ball grid array socket called Socket 754; an integrated DDR memory controller (instead of using the North Bridge for memory connections); an improved version of the AMD-developed HyperTransport connection to AGP, PCI, and other components; and an improved heatsink-mounting solution. It supports MMX and AMD 3DNow! Instructions for multimedia and uses a performance-rating system similar to that used by 32-bit Athlon processors. See also Athlon.
ATM (asynchronous transfer mode)  A high-bandwidth, low-delay, packet-like switching and multiplexing technique. Usable capacity is segmented into fixed-size cells consisting of header and information fields, allocated to services on demand.

attribute byte  A byte of information, held in the directory entry of any file or folder, that describes various attributes of the file or folder, such as whether it is read-only or has been backed up since it last was changed. Attributes can be set by the DOS ATTRIB command or with Windows Explorer.

ATX  A motherboard and power supply form factor standard designed by Intel and introduced in 1995. It is characterized by a double row of rear external I/O connectors on the motherboard, a single keyed power supply connector, memory and processor locations that are designed not to interfere with the installation of adapter cards, and an improved cooling flow. The current specification—ATX 2.0—was introduced in December 1996.

audio  A signal that can be heard, such as through the speaker of the PC. Many PC diagnostic tests use both visual (onscreen) codes and audio signals.

audio frequencies  Frequencies that can be heard by the human ear (approximately 20Hz–20,000Hz).

auto-answer  A setting in modems enabling them to answer incoming calls over the phone lines automatically.

auto-dial  A feature in modems enabling them to dial phone numbers without human intervention.

auto-disconnect  A modem feature that enables a modem to hang up the telephone line when the modem at the other end hangs up.

auto-redial  A modem or software feature that automatically redials the last number dialed if the number is busy or does not answer.

AUTOEXEC.BAT  A special batch file DOS and Windows 9x execute at startup. Contains any number of DOS commands that are executed automatically, including the capability to start programs at startup. See also batch file.

automatic head parking  Disk drive head parking performed whenever the drive is powered off. Found in all modern hard disk drives with a voice-coil actuator.

available memory  Memory currently not in use by the operating system, drivers, or applications, which can be used to load additional software.

average access time  The average time it takes a disk drive to begin reading any data placed anywhere on the drive. This includes the average seek time, which is when the heads are moved, as well as the latency, which is the average amount of time required for any given data sector to pass underneath the heads. Together, these factors make up the average access time. See also average seek time and latency.

average latency  The average time required for any byte of data stored on a disk to rotate under the disk drive’s read/write head. Equal to one-half the time required for a single rotation of a platter.

average seek time  The average amount of time it takes to move the heads from one random cylinder location to another, usually including any head settling time. In many cases, the average seek time is defined as the seek time across one third of the total number of cylinders.

AVI (audio video interleave)  A storage technique developed by Microsoft for its Video for Windows product that combines audio and video into a single frame or track, saving valuable disk space and keeping audio in synchronization with the corresponding video. AVI files are widely supported by media players and video production programs.

AWG  American Wire Gauge, a U.S. standard for measuring the thickness of copper and aluminum wire for electrical and data-transmission use. Thinner wire is used to save space and for short distances, but thicker wire has less resistance and is better for long wire runs.

B Channel  The bearer channel in an ISDN network, it’s used to carry data at a rate of 64KBps. See also BRI.

backbone  The portion of the Internet or wide area network (WAN) transmission wiring that connects the main Internet/WAN servers and routers and is responsible for carrying the bulk of the Internet/WAN data.

backplane  A rarely used motherboard design in which the components typically found on a motherboard are instead located on an expansion adapter card plugged into a slot. In these systems, the board with the slots is the backplane. The PCI Industrial Computer Manufacturers Group (PICMG) single-board computer designs for rackmount systems are the primary users of backplane designs today.

backup  The process of duplicating a file or library onto a separate piece of media. It’s good insurance against the loss of an original. Depending on how the backup was made, the data might need to be restored with a special program before reuse.

backup disk  Contains information copied from another disk. Used to ensure that original information is not destroyed or altered.

backward compatibility  The design of software and hardware to work with previous versions of the same software or hardware.

bad sector  A disk sector that can’t hold data reliably because of a media flaw or damaged format markings.

bad track table  A label affixed to the casing of an ST412/506 or ESDI hard disk drive that tells which tracks are flawed and incapable of holding data. The listing is entered into the low-level formatting program. Modern ATA (IDE) and SCSI drives are low-level formatted during manufacture and don’t have (or need) a bad track table.
Appendix A

base memory

The amount of memory available to the operating system or application programs within the first megabyte, accessible in the processor's real mode.

baseband transmission

The transmission of digital signals over a limited distance. ARCnet and Ethernet local area networks use baseband signaling. Contrasts with broadband transmission, which refers to the transmission of analog signals over a greater distance.

BASIC (Beginner’s All-purpose Symbolic Instruction Code)

A popular computer programming language originally developed by John Kemeny and Thomas Kurtz in the mid-1960s at Dartmouth College. Normally, BASIC is an interpretive language, meaning that each statement is translated and executed as it is encountered, but it can be a compiled language, in which all the program statements are compiled before execution. Microsoft Visual Basic, a popular development environment for Windows, is not related to BASIC.

batch file

A set of commands stored in a disk file for execution by the operating system. A special batch file called AUTOEXEC.BAT is executed by DOS each time the system is started. All DOS and Windows batch files have a .BAT file extension.

Baud

A unit of signaling speed denoting the number of discrete signal elements that can be transmitted per second. The word baud is derived from the name of J.M.E. Baudot (1845–1903), a French pioneer in the field of printing telegraphy and the inventor of Baudot code. Although technically inaccurate, baud rate commonly is used to mean bit rate. Because each signal element or baud can translate into many individual bits, bits per second (bps) usually differs from baud rate. A rate of 2,400 baud means that 2,400 frequency or signal changes per second are being sent, but each frequency change can signal several bits of information. For example, 33.6Kbps modems actually transmit only 2,400 baud.

Baudot code

A 5-bit code used in many types of data communications, including teletype (TTY), radio teletype (RTTY), and telecommunications devices for the deaf (TDD). Baudot code has been revised and extended several times. See also baud.

Bay

An opening in a computer case or chassis that holds disk drives.

BBS (bulletin board system)

A computer that operates with a program and a modem to enable other computers with modems to communicate with it, often on a round-the-clock basis. Although BBSs were once the primary means of distributing information and software, the Internet has almost completely replaced BBSs.

benchmark

A test or set of tests designed to compare the performance of hardware or software. A popular set of benchmarks for PC hardware is the PC Magazine benchmarks, such as Business Winstone, WinBench, and others. You can order CDs or download selected benchmarks from www.veritest.com/benchmarks/pcmbmk.asp.

balanced signal

Refers to signals consisting of equal currents moving in opposite directions. When balanced or nearly balanced signals pass through twisted-pair lines, the electromagnetic interference effects—such as crosstalk caused by the two opposite currents—largely cancel each other out. Differential signaling (used by some types of SCSI interfaces) is a method that uses balanced signals.

balun

Short for balanced/unbalanced. A type of transformer that enables balanced cables to be joined with unbalanced cables. Twisted-pair (balanced) cables, for example, can be joined with coaxial (unbalanced) cables if the proper balun transformer is used.

bandwidth

1) Generally, the measure of the range of frequencies within a radiation band required to transmit a particular signal. The difference between the lowest and highest signal frequencies. The bandwidth of a computer monitor is a measure of the rate at which a monitor can handle information from the display adapter. The wider the bandwidth, the more information the monitor can carry and the greater the resolution. 2) Used to describe the data-carrying capacity of a given communications circuit or pathway. The bandwidth of a circuit is a measure of the rate at which information can be passed.

bank

The collection of memory chips or modules that make up a block of memory readable or writeable by the processor in a single cycle. This block, therefore, must be as large as the data bus of the particular microprocessor. In PC systems, the processor data bus (and therefore the bank size) is usually 8, 16, 32, or 64 bits wide. Optionally, some systems also incorporate an additional parity or ECC bit for each 8 data bits, resulting in a total of 9, 18, 36, or 72 bits (respectively) for each bank. Memory in a PC always must be added or removed in full-bank increments. The number of memory chips or modules that make up a bank varies with the width of the memory in bits and the size of the processor's data bus. For example, a K6-2 processor has a data bus that is 64 bits wide. If the motherboard uses 72-pin SIMMs (which are 32 data bits wide), a bank is two SIMMs. However, if the motherboard uses DIMMs, which are 64 data bits wide, a bank is one DIMM.

bar code

The code used on consumer products and inventory parts for identification purposes. Consists of bars of varying thickness that represent characters and numerals that are read with an optical reader. The most common version is called the universal product code (UPC).

base-2

Refers to the computer numbering system that consists of two numerals: 0 and 1. Also called binary.

base address

Starting location for a consecutive string of memory or I/O addresses/ports.

base memory

The amount of memory available to the operating system or application programs within the first megabyte, accessible in the processor's real mode.
bezel  A cosmetic panel that covers the face of a drive or some other device.

Bézier curve  A mathematical method for describing a curve, often used in illustration and CAD programs to draw complex shapes.

BGA (ball grid array)  A packaging technology used by Socket 478 Pentium 4 and Celeron processors, as well as many recent motherboard chipsets and video card memory chips. BGA uses small solder balls instead of pin connectors to enable more signaling paths to exist in a smaller space and improve signal accuracy.

bidirectional  1) Refers to lines over which data can move in two directions, such as a data bus or telephone line. 2) Refers to the capability of a printer to print from right to left and from left to right alternately.

binary  See base-2.

BIOS (basic input/output system)  The part of an operating system that handles the communications between the computer and its peripherals. Often burned into read-only memory (ROM) chips or rewritable flash (EEPROM) memory chips found on motherboards and expansion cards, such as video cards and SCSI and ATA/IDE host adapters. See also firmware.

bipolar  A category of semiconductor circuit design that was used to create the first transistor and the first integrated circuit. Bipolar and CMOS are the two major transistor technologies. Almost all personal computers use CMOS technology chips. CMOS uses far less energy than bipolar.

bisynchronous (binary synchronous control)  An earlier protocol developed by IBM for software applications and communicating devices operating in synchronous environments. The protocol defines operations at the link level of communications—for example, the format of data frames exchanged between modems over a phone line.

bit binary digit  Represented logically by 0 or 1 and electrically by 0 volts and (typically) 5 volts. Other methods are used to represent binary digits physically (tones, different voltages, lights, and so on), but the logic is always the same.

bit density  Expressed as bits per inch (BPI). Defines how many bits can be written onto one linear inch of a track. Sometimes also called linear density.

bit depth  The number of bits used to describe the color of each pixel on a computer display. For example, a bit depth of two (2^2) means the monitor can display only black and white pixels; a bit depth of four (2^4) means the monitor can display 16 different colors; a bit depth of eight (2^8) allows for 256 colors; and so on.

bitmap  A method of storing graphics information in memory, in which a bit devoted to each pixel (picture element) onscreen indicates whether that pixel is on or off. A bitmap contains a bit for each point or dot on a video display screen and enables fine resolution because any point or pixel onscreen can be addressed. A greater number of bits can be used to describe each pixel’s color, intensity, and other display characteristics.

blank or blanking interval  A period in which no video signal is received by a monitor while the videodisc or digital video player searches for the next video segment or frame to display.

block  A string of records, words, or characters formed for technical or logic reasons and to be treated as an entity.

block diagram  The logical structure or layout of a system in graphics form. Does not necessarily match the physical layout and does not specify all the components and their interconnections.

Blue Book  The standard for enhanced CDs (CD-E). CD-E media contains both music (for play on standard CD players) and computer content. Developed by Philips and Sony in 1995.

blue screen of death  A system crash in Windows that replaces the normal desktop with a blue screen with white text reporting the problem and locks up the system. Also referred to as a BSOD, this condition can be triggered by defective memory, file system errors, and other system problems.

Bluetooth  An emerging short-range networking standard, Bluetooth is designed to enable PCs, mobile phones, input devices, and PDAs to exchange data with each other. Bluetooth uses the same 2.4GHz frequency range used by some types of wireless phones and by the IEEE 802.11b Wi-Fi wireless Ethernet network. Bluetooth has a speed of 1Mbps or 2Mbps, depending on the version.

BMP  A Windows graphics format that can be device dependent or independent. Device-independent BMP files (DIB) are coded for translation to a wide variety of displays and printers.

BNC (Bayonet-Neill-Concelman)  Also known as British-Navy-Connector, Baby-N-Connector, or Bayonet-Nut-Coupler, this bayonet-locking connector is noted for its excellent shielding and impedance-matching characteristics, resulting in low noise and minimal signal loss at any frequency up to 4GHz. It is used in Ethernet 10BASE-2 networks (also known as IEEE 802.3 or Thinnet) to terminate coaxial cables. It is also used for some high-end video monitors. BNC is named for its connection type (bayonet) and its co-developers.

bonding  In ISDN, joining two 64Kbps B-channels to achieve 128Kbps speed. Bonding can also be used with analog modems that use the Multilink Point-to-Point protocol that is supported by Windows 98 and newer versions but by only a few ISPs.
Appendix A

**Boolean operation** Any operation in which each of the operands and the result take one of two values. A Boolean search can be performed with many search engines used on Web sites and help files using operators such as AND, OR, and NOT.

**boot** To load a program into the computer. The term comes from the phrase “pulling a boot on by the bootstrap.”

**boot manager** A program that enables you to select which active partition to boot from. Often supplied with aftermarket disk-partitioning programs, such as PartitionMagic, or installed by default when you install a Windows upgrade into a separate disk partition instead of replacing your old version. See also active partition.

**boot record** The first sector on a disk or partition that contains disk parameter information for the BIOS and operating system as well as bootstrap loader code that instructs the system how to load the operating system files into memory, thus beginning the initial boot sequence to boot the machine.

**boot sector** See boot record.

**boot sector virus** A virus designed to occupy the boot sector of a disk. Any attempt to start or boot a system from this disk transfers the virus to the hard disk, after which it subsequently is loaded every time the system is started. Many older PC viruses, particularly those spread by infected floppy disks, are boot sector viruses.

**bootstrap** A technique or device designed to bring itself into a desired state by means of its own action. The term is used to describe the process by which a device such as a PC goes from its initial power-on condition to a running condition without human intervention. See also boot.

**boule** Purified, cylindrical silicon crystals from which semiconducting electronic chips, including microprocessors, memory, and other chips, in a PC are manufactured. Also called an ingot.

**bps (bits per second)** The number of binary digits, or bits, transmitted per second. Sometimes confused with baud.

**branch prediction** A feature of fifth-generation (Pentium and higher) processors that attempts to predict whether a program branch will be taken and then fetches the appropriate following instructions.

**BRI** Short for basic rate interface, it’s a form of ISDN used in home and small business applications. A 2B+1D BRI service has two B channels and a single D channel for signaling and control uses.

**bridge** In local area networks, an interconnection between two similar networks. Also the hardware equipment used to establish such an interconnection.

**broadband transmission** A term used to describe analog transmission. Requires modems for connecting terminals and computers to the network. Using frequency division multiplexing, many signals or sets of data can be transmitted simultaneously. The alternative transmission scheme is baseband, or digital, transmission.

**brownout** An AC supply voltage drop in which the power does not shut off entirely but continues to be supplied at lower-than-normal levels.

**BSOD** See blue screen of death.

**bubble memory** A special type of nonvolatile read/write memory introduced by Intel in which magnetic regions are suspended in crystal film and data is maintained when the power is off. A typical bubble memory chip contains about 512KB, or more than four million bubbles. Bubble memory failed to catch on because of slow access times measured in milliseconds. It has, however, found a niche use as solid-state “disk” emulators in environments in which conventional drives are unacceptable, such as in military or factory use.

**buffer** A block of memory used as a holding tank to store data temporarily. Often positioned between a slower peripheral device and the faster computer. All data moving between the peripheral and the computer passes through the buffer. A buffer enables the data to be read from or written to the peripheral in larger chunks, which improves performance. A buffer that is x bytes in size usually holds the last x bytes of data that moved between the peripheral and CPU. This method contrasts with that of a cache, which adds intelligence to the buffer so that the most often accessed data, rather than the last accessed data, remains in the buffer (cache). A cache can improve performance greatly over a plain buffer.

**bug** An error or a defect in a program; it can be corrected through program patches (for applications or operating systems) or firmware updates (for BIOS chips).

**burn-in** The operation of a circuit or equipment to establish that its components are stable and to screen out defective ports or assemblies.

**BURN-Proof** Short for buffer underrun error-proof, it’s a technology developed by Sanyo to prevent buffer underruns during the creation of CD-Rs. BURN-Proof, which has been licensed to many CD-RW drive makers, enables a drive to pause the burning process and continue after sufficient data is available in the drive’s buffer. The drive and CD-mastering software must both support BURN-Proof for this feature to work. Ricoh’s JustLink works in a similar fashion. See also lossless linking.

**burst mode** A memory-cycling technology that takes advantage of the fact that most memory accesses are consecutive in nature. After setting up the row and column addresses for a given access, using burst mode can then access the next three adjacent addresses with no additional latency.
**Burst Static RAMs (BSRAMs)**  Short for Pipeline Burst SRAM, BSRAMs are a common type of static RAM chip used for memory caches where access to subsequent memory locations after the first byte is accessed takes fewer machine cycles.

**bus**  A linear electrical signal pathway over which power, data, and other signals travel. It is capable of connecting to three or more attachments. A bus is generally considered to be distinct from radial or point-to-point signal connections. The term comes from the Latin *omnibus*, meaning “for all.” When used to describe a topology, bus always implies a linear structure.

**bus mouse**  An obsolete type of mouse used in the 1980s that plugs into a special mouse expansion board (occasionally incorporated into a video card) instead of a serial port or motherboard mouse port. The bus mouse connector looks similar to a motherboard mouse (sometimes called PS/2 mouse) connector, but the pin configurations are different and not compatible.

**busmaster**  An intelligent device that, when attached to the Micro Channel, EISA, VLB, or PCI bus, can bid for and gain control of the bus to perform its specific task without processor intervention. Most recent motherboards incorporate busmastering ATA/IDE host adapters, but this feature must be enabled in both the BIOS and through the installation of Windows drivers to be effective.

**byte**  A collection of bits that makes up a character or other designation. Generally, a byte is 8 data bits. When referring to system RAM, an additional parity (error-checking) bit is also stored (see *parity*), making the total 9 bits.

**C**  A high-level computer programming language. A programming language frequently used on mainframes, minis, and PC computer systems. C++ is a popular variant.

**C3**  A Socket 370-compatible processor developed by VIA Technology from the Cyrix “Joshua” after VIA purchased Cyrix from National Semiconductor. The C3 is noted for its very small die size and cool operation, making it a suitable choice for portable computers and embedded computers.

**CAB file**  Short for cabinet file, the archive file type used by Microsoft to distribute recent versions of Windows and applications. Some recent versions of WinZip can be used to manually extract files from a .CAB file; you can also open .CAB files within Windows Explorer with Windows 98 after you install the Windows 98 Plus! package and with Windows Explorer in Windows 2000, Windows Me, and Windows XP.

**cable modem**  A broadband Internet device that receives data through the cable TV system. The cable modem can be a one-way device (using a conventional analog modem for dialing and uploading) or a two-way device.

**CableLabs Certified Cable Modem**  A cable modem that meets the Data or Cable Service Interface Specifications (DOCSIS) standards for modulation and protocols. Various brands and models of modems meet this standard on cable networks that also meet this standard. DOCSIS/CableLabs Certified Cable Modems can be purchased as well as leased.

**cache**  An intelligent buffer. By using an intelligent algorithm, a cache contains the data accessed most often between a slower peripheral device and the faster CPU. See also *L1 cache, L2 cache, and disk cache*.

**caddy**  A cartridge designed to hold a CD or DVD disc. Some CD drives use caddies, particularly in harsh or industrial environments. DVD-RAM drives also use a caddy to protect the disc.

**CAM (Common Access Method)**  A committee formed in 1988 that consists of several computer peripheral suppliers and is dedicated to developing standards for a common software interface between SCSI peripherals and host adapters.

**candela**  Abbreviated cd, a candela is the standard unit of measurement for luminosity. The brightness of LCDs and other types of displays is sometimes measured in cd units.

**capacitor**  A device consisting of two plates separated by insulating material and designed to store an electrical charge.

**card**  A printed circuit board containing electronic components that form an entire circuit, usually designed to plug into a connector or slot. Sometimes also called an adapter.

**card edge connector**  See *edge connector*.

**CardBus**  A PC Card (PCMCIA) specification for a 32-bit interface that runs at 33MHz and provides 32-bit data paths to the computer’s I/O and memory systems, as well as a new shielded connector that prevents CardBus devices from being inserted into slots that do not support the latest version of the PC Card (PCMCIA) standard. CardBus slots can also be used with normal 16-bit PC Card (PCMCIA) devices.

**carpal tunnel syndrome**  A painful hand injury that gets its name from the narrow tunnel in the wrist that connects ligament and bone. When undue pressure is put on the tendons, they can swell and compress the median nerve, which carries impulses from the brain to the hand, causing numbness, weakness, tingling, and burning in the fingers and hands. Computer users get carpal tunnel syndrome primarily from improper keyboard ergonomics that result in undue strain on the wrist and hand.
carrier  A continuous frequency signal capable of being either modulated or impressed with another information-carrying signal. The reference signal used for the transmission or reception of data. The most common use of this signal with computers involves modem communications over phone lines. The carrier is used as a signal on which the information is superimposed.

**carrier detect signal**  A modem interface signal that indicates to the attached data terminal equipment (DTE) that it is receiving a signal from the distant modem. Defined in the RS-232 specification. Same as the received line-signal detector.

**CAT**  Short for category, it describes the ANSI/EIA 568 wiring standards used for data transmission. The most common CAT standards include CAT 3 (16Mbps maximum data rate, suitable for 10BASE-T Ethernet) and CAT 5 (used for 100BASE-T Fast Ethernet or 1000BASE-T Gigabit Ethernet).

**cathode ray tube (CRT)**  A device that contains electrodes surrounded by a glass sphere or cylinder and displays information by creating a beam of electrons that strike a phosphor coating inside the display unit. This device is most commonly used in computer monitors and terminals.

**CAV (constant angular velocity)**  An optical disk recording format in which the data is recorded on the disk in concentric circles. CAV disks are rotated at a constant speed. This is similar to the recording technique used on floppy disk drives. CAV limits the total recorded capacity compared to CLV (constant linear velocity), which also is used in optical recording. See also CLV.

**CCITT**  An acronym for the Comité Consultatif International de Télégraphique et Téléphonique (in English, the International Telegraph and Telephone Consultative Committee or the Consultative Committee for International Telegraph and Telephone). Renamed ITU (International Telecommunications Union). See also ITU.

**CCS (common command set)**  A set of SCSI commands specified in the ANSI SCSI-1 Standard X3.131-1986 Addendum 4.B. All SCSI devices must be capable of using the CCS to be fully compatible with the ANSI SCSI-1 standard.

**CD (compact disc or compact audio disc)**  A 4.75” (12cm) optical disc that contains information encoded digitally in the constant linear velocity (CLV) format. This popular format for high-fidelity music offers 90 decibels signal/noise ratio, 74 minutes of digital sound, and no degradation of quality from playback. The standards for this format (developed by NV Philips and Sony Corporation) are known as the Red Book. The official (and rarely used) designation for the audio-only format is CD-DA (compact disc-digital audio). The simple audio format is also known as CD-3.

**CD burner**  Refers to either a CD-R or CD-RW drive. See also DVD burner.

**CD+G (Compact Disc+Graphics)**  A CD format that includes extended graphics capabilities as written into the original CD-ROM specifications. Includes limited video graphics encoded into the CD subcode area. Originally developed and marketed by Warner New Media (later Time Warner Interactive), it’s a popular choice for self-contained karaoke systems.

**CD-I (Compact Disc-Interactive)**  A compact disc format released in October 1991 that provides audio, digital data, still graphics, and motion video. The standards for this format (developed by NV Philips and Sony Corporation) are known as the Green Book. CD-I did not catch on with consumers and is now considered obsolete.

**CD+MIDI (Compact Disc+Musical Instrument Digital Interface)**  A CD format that adds to the CD+G format digital audio, graphics information, and musical instrument digital interface (MIDI) specifications and capabilities. Originally developed and marketed by Warner New Media (later Time Warner Interactive).

**CD-R (Compact Disc-Recordable, sometimes called CD-writable)**  CD-R discs are compact discs that can be recorded and read as many times as desired. CD-R is part of the Orange Book standard defined by ISO. CD-R technology is used for mass production of multimedia applications. CD-R discs can be compatible with CD-ROM, CD-ROM XA, and CD audio. Orange Book specifies multisession capabilities, which enable data recording on the disc at various times in several recording sessions. Multisession capability enables data such as digital photos, digital music, or other types of data files to be added to a single disc on different occasions. The original capacity of CD-R media was 650MB (74 minutes), but most recent CD-ROM and compatible optical drives support the larger 700MB (80-minute) media.

**CD-ROM (compact disc-read-only memory)**  A 4.75” laser-encoded optical memory storage medium with the same constant linear velocity (CLV) spiral format as audio CDs and some videodiscs. CD-ROMs can hold about 650MB of data and require more error-correction information than the standard prerecorded compact audio discs. The standards for this format (developed by NV Philips and Sony Corporation) are known as the Yellow Book. See also CD-ROM XA.

**CD-ROM drive**  A device that retrieves data from a CD-ROM disc; it differs from a standard audio CD player by the incorporation of additional error-correction circuitry. CD-ROM drives usually can also play music from audio CDs.
CD-ROM XA (compact disc-read-only memory extended architecture) The XA standard was developed jointly by Sony, Philips, and Microsoft in 1988 and is now part of the Yellow Book standard. XA is a built-in feature of newer CD-ROM drives and supports simultaneous sound playback with data transfer. Non-XA drives support either sound playback or data transfer, but not both simultaneously. XA also enables data compression right on the disk, which also can increase data transfer rates.

CD-RW (compact disc-rewritable) A type of rewritable CD-ROM technology defined in Part III of the Orange Book standard that uses a different type of disc, which the drive can rewrite at least 1,000 times. CD-RW drives also can be used to write CD-R discs, and they can read CD-ROMs. CD-RWs have a lower reflectivity than standard CD-ROMs, and CD-ROM drives must be of the newer multiread variety to read them. CD-RW was initially known as CD-E (for CD-erasable).

CD Video A CD format introduced in 1987 that combines 20 minutes of digital audio and 6 minutes of analog video on a standard 4.75" CD. Upon introduction, many firms renamed 8" and 12" videodiscs CDV in an attempt to capitalize on the consumer popularity of the audio CD. The term fell out of use in 1990 and was replaced in some part by “laser disc” and, more recently, “DVD.” See also video-on-CD.

CD-WO (compact disc-write once) A variant on CD-ROM that can be written to once and read many times; developed by NV Philips and Sony Corporation. Also known as CD-WORM (CD-write once/read many), CD-recordable, or CD-writable. Standards for this format are known as the Orange Book.

CD-WORM See CD-WO.

CDMA Short for code division multiple access, a popular family of wireless protocols used in cellular phones for Internet and email access.

Celeron A family of processors that are low-cost versions of the Pentium II, Pentium III, and Pentium 4 processors. The major differences include a smaller amount of L2 cache and lower clock speeds.

Centronics connector Refers to one of two types of cable connectors used with either parallel (36-pin Centronics connector) or SCSI (50-pin edge connector) devices.

ceramic substrate A thin, flat, fired-ceramic part used to hold an IC chip (usually made of beryllium oxide or aluminum oxide).

CERN (Conseil Européen pour la Recherche Nucléaire; The European Laboratory for Particle Physics) The site in Geneva where the World Wide Web was created in 1989.

CGA (color graphics adapter) A type of PC video display adapter introduced by IBM on August 12, 1981, which supports text and graphics. Text is supported at a maximum resolution of 80×25 characters in 16 colors with a character box of 8×8 pixels. Graphics are supported at a maximum resolution of 320×200 pixels in 16 colors or 640×200 pixels in 2 colors. The CGA outputs a TTL (digital) signal with a horizontal scanning frequency of 15.75kHz and supports TTL color or NTSC composite displays.

channel 1) Any path along which signals can be sent. 2) In ISDN, data bandwidth is divided into two B-channels that bear data and one D-channel that carries information about the call.

character A representation—coded in binary digits—of a letter, number, or other symbol.

character set All the letters, numbers, and characters a computer can use to represent data. The ASCII standard has 256 characters, each represented by a binary number from 1 to 256. The ASCII set includes all the letters in the alphabet, numbers, most punctuation marks, some mathematical symbols, and other characters.

charge coupled device A light-sensing and storage device used in scanners and digital cameras to capture the pixels.

check bit See parity.

checksum Short for summation check, a technique for determining whether a package of data is valid. The package, a string of binary digits, is added up and compared with the expected number.

chip Another name for an IC, or integrated circuit. Housed in a plastic or ceramic carrier device with pins for making electrical connections.

chip carrier A ceramic or plastic package that carries an integrated circuit.

chipset A single chip or pair of chips that integrates into it the clock generator, bus controller, system timer, interrupt controller, DMA controller, CMOS RAM/clock, and keyboard controller. See also North Bridge and South Bridge.

CHS (cylinder head sector) The term used to describe the nontranslating scheme used by the BIOS to access IDE drives that are less than or equal to 528MB in capacity. See also LBA.

CIF (common image format) The standard sample structure that represents the picture information of a single frame in digital HDTV, independent of frame rate and sync/blank structure. The uncompressed bit rate for transmitting CIF at 29.97 frames/sec is 36.45Mbps.

circuit A complete electronic path.

circuit board The collection of circuits gathered on a sheet of plastic, usually with all contacts made through a strip of pins. The circuit board usually is made by chemically etching metal-coated plastic.
CISC (complex instruction set computer)
Refers to traditional computers that operate with large sets of processor instructions. Most modern computers, including the Intel 80xxx processors, are in this category. CISC processors have expanded instruction sets that are complex in nature and require several to many execution cycles to complete. This structure contrasts with RISC (reduced instruction set computer) processors, which have far fewer instructions that execute quickly.

clean room 1) A dust-free room in which certain electronic components (such as chips or hard disk drives) must be manufactured and serviced to prevent contamination. Rooms are rated by Class numbers. A Class 100 clean room must have fewer than 100 particles larger than 0.5 microns per cubic foot of space. 2) A legal approach to copying software or hardware in which one team analyzes the product and writes a detailed description, followed by a second team who reads the description written by the first and then develops a compatible version of the product. When done correctly, such a design methodology will survive a legal attack.

client/server A type of network in which every computer is either a server with a defined role of sharing resources with clients or a client that can access the resources on the server.

clock The source of a computer's timing signals. It synchronizes every operation of the CPU.

clock multiplier A processor feature where the internal core runs at a higher speed than the motherboard or processor bus. See also overclocking.

clock speed A measurement of the rate at which the clock signal for a device oscillates, usually expressed in millions of cycles per second (MHz).

clone Originally referred to an IBM-compatible computer system that physically as well as electrically emulates the design of one of IBM's personal computer systems. More currently, it refers to any PC system running an Intel or compatible processor in the 80x86 family.

cluster Also called allocation unit. A group of one or more sectors on a disk that forms a fundamental unit of storage to the operating system. Cluster, or allocation unit, size is determined by the operating system when the disk is formatted. Larger clusters generally offer faster system performance but waste disk space.

CLV (constant linear velocity) An optical recording format in which the spacing of data is consistent throughout the disk and the rotational speed of the disk varies depending on which track is being read. Additionally, more sectors of data are placed on the outer tracks compared to the inner tracks of the disk, which is similar to zone recording on hard drives. CLV drives adjust the rotational speed to maintain a constant track velocity as the diameter of the track changes. CLV drives also rotate more quickly near the center of the disk and more slowly toward the edge. Rotational adjustment maximizes the amount of data that can be stored on a disk. CD audio and CD-ROM use CLV recording. See also CAV.

CMOS (complementary metal-oxide semiconductor) A type of chip design that requires little power to operate. In PCs, a battery-powered CMOS memory and clock chip is used to store and maintain the clock setting and system configuration information.

CMYK (cyan magenta yellow black) The standard four-color model used for printing.

CNR Short for Communications and Networking Riser, it was developed by Intel as a replacement for the AMR. CNR enables motherboard makers to offer low-cost modem, networking, and audio features through a special expansion slot. Unlike AMR, a CNR slot can be built as a shared slot with a PCI slot. See also AMR.

coated media Hard disk platters coated with a red-dish iron-oxide medium on which data is recorded.

c coaxial cable Also called coax cable. A data-transmission medium noted for its wide bandwidth, immunity to interference, and high cost compared to other types of cable. Signals are transmitted inside a fully shielded environment, in which an inner conductor is surrounded by a solid insulating material and then an outer conductor or shield. Used in many local area network systems, such as Ethernet and ARCnet.

COBOL (Common Business-Oriented Language) A high-level computer programming language used primarily by some larger companies. It has never achieved popularity on personal and small business computers.

code page A table used in DOS 3.3 and later that sets up the keyboard and display characters for various foreign languages.

code page switching A DOS feature in versions 3.3 and later that changes the characters displayed onscreen or printed on an output device. Primarily used to support foreign-language characters. Requires an EGA or better video system and an IBM-compatible graphics printer.

CODEC (coder-decoder) A device that converts voice signals from their analog form to digital signals acceptable to more modern digital PBXs and digital transmission systems. It then converts those digital signals back to analog so you can hear and understand what the other party is saying. Also refers to compression/decompression software used in the creation of digital audio and video files, such as MP3 and MPEG, and for videophone programs.
coercivity  A measurement in units of oersteds of the amount of magnetic energy to switch or “coerce” the flux change in the magnetic recording media. High-coercivity disk media require a stronger write current.

cold boot  The act of starting or restarting a computer from a powered-off state. If the system is on, this requires cycling the power off and then back on. A cold boot causes all RAM to be forcibly cleared. See also warm boot.

collision  In a LAN, if two computers transmit a packet of data at the same time on the network, the data can become garbled, which is known as a collision.

collision detection/avoidance  A process used on a LAN to prevent data packets from interfering with each other and to determine whether data packets have encountered a collision and initiate a resend of the affected packets.

color graphics adapter  See CGA.

color palette  The colors available to a graphics adapter for display.

COM port  A serial port on a PC that conforms to the RS-232 standard. See also RS-232.

COMDEX  The largest international computer trade show and conference in the world. COMDEX/Fall is held in Las Vegas during October, and COMDEX/Spring usually is held in Chicago or Atlanta during April.

command  An instruction that tells the computer to start, stop, or continue an operation.

COMMAND.COM  An operating system file that is loaded last when the computer is booted. The command interpreter or user interface and program-loader portion of DOS.

command interpreter  The operating system program that controls a computer’s shell or user interface. The command interpreter for MS-DOS (and the command-line sessions in Windows 9x/Me) is COMMAND.COM; the command interpreter for the graphical shell in Windows versions through 9x/Me is WIN.COM; the command interpreter for NT-based versions of Windows (including Windows 2000 and Windows XP) is CMD.COM.

common  The ground or return path for an electrical signal. If it’s a wire, it usually is colored black.

common mode noise  Noise or electrical disturbances that can be measured between a current- or signal-carrying line and its associated ground. Common mode noise is frequently introduced to signals between separate computer equipment components through the power distribution circuits. It can be a problem when single-ended signals are used to connect different equipment or components that are powered by different circuits.

CompactFlash  An ATA flash memory card physical format approximately one third the size of a standard PC Card. Often abbreviated CF or CF+, CompactFlash cards are identical in function to standard ATA Flash PC Cards (PCMCIA) but use 50 pin connectors instead of 68. ATA flash cards contain built-in disk controller circuitry to enable the card to function as a solid-state disk drive. CF cards can plug into a CompactFlash socket or with an adapter into a standard Type I or II PC Card (PCMCIA) slot. CF cards are used by many types of digital cameras.

compatible  1) In the early days of the PC industry when IBM dominated the market, a term used to refer to computers from other manufacturers that had the same features as a given IBM model. 2) In general, software or hardware that conforms to industry standards or other de facto standards so that it can be used in conjunction with or in lieu of other versions of software or hardware from other vendors in a like manner.

compiler  A program that translates a program written in a high-level language into its equivalent machine language. The output from a compiler is called an object program.

complete backup  A backup of all information on a hard disk, including the directory tree structure.

composite video  Television picture information and sync pulses combined. The complete wave form of the color video signal composed of chrominance and luminance picture information; blanking pedestal; field, line, and color-sync pulses; and field-equalizing pulses. Some video cards have an RCA jack that outputs a composite video signal. See also RGB.

compressed file  A file that has been reduced in size via one or more compression techniques. See also archive file.

computer  Device capable of accepting data, applying prescribed processes to this data, and displaying the results or information produced.

computer-based training (CBT)  The use of a computer to deliver instruction or training; also known as computer-aided (or assisted) instruction (CAI), computer-aided learning (CAL), computer-based instruction (CBI), and computer-based learning (CBL).

CONFIG.SYS  A file that can be created to tell DOS how to configure itself when the machine starts up. It can load device drivers, set the number of DOS buffers, and so on.

configuration file  A file kept by application software to record various aspects of the software’s configuration, such as the printer it uses. Windows uses .INI files and the Windows Registry to control its configuration.

console  The unit, such as a terminal or a keyboard, in your system with which you communicate with the computer.
**contiguous**  Touching or joined at the edge or boundary, in one piece.

**continuity**  In electronics, an unbroken pathway. Testing for continuity usually means testing to determine whether a wire or other conductor is complete and unbroken (by measuring 0 ohms). A broken wire shows infinite resistance (or infinite ohms).

**control cable**  The wider of the two cables that connect an ST-506/412 or ESDI hard disk drive to a controller card. A 34-pin cable that carries commands and acknowledgments between the drive and controller.

**controller**  The electronics that control a device, such as a hard disk drive, and intermediate the passage of data between the device and computer.

**controller card**  An adapter holding the control electronics for one or more devices, such as hard disks. Ordinarily occupies one of the computer's slots.

**conventional memory**  The first megabyte or first 640KB of system memory accessible by an Intel processor in real mode. Sometimes called base memory.

**convergence**  Describes the capability of a color monitor to focus the three colored electron beams on a single point. Poor convergence causes the characters onscreen to appear fuzzy and can cause headaches and eyestrain.

**coprocessor**  An additional computer processing unit designed to handle specific tasks in conjunction with the main or central processing unit.

**copy protection**  A hardware or software scheme to prohibit making illegal copies of a program.

**core**  An old-fashioned term for computer memory.

**core speed**  The internal speed of a processor. With all modern processors, this speed is faster than the system bus speed, and that speed relationship is regulated by the clock multiplier in the processor.

**CP/M (Control Program for Microcomputers, originally Control Program/Monitor)**  An operating system created by Gary Kildall, the founder of Digital Research. Created for the old 8-bit microcomputers that used the 8080, 8085, and Z-80 microprocessors. It was the dominant operating system in the late 1970s and early 1980s for small computers used in business environments.

**cps (characters per second)**  A data transfer rate generally estimated from the bit rate and character length. At 2,400bps, for example, 8-bit characters with start and stop bits (for a total of 10 bits per character) are transmitted at a rate of approximately 240cps. Some protocols, such as V.42 and MNP, employ advanced techniques such as longer transmission frames and data compression to increase characters per second.

**CPU (central processing unit)**  The computer's microprocessor chip; the brains of the outfit. Typically, an IC using VLSI (very-large-scale integration) technology to pack several functions into a tiny area. The most common electronic device in the CPU is the transistor, of which several thousand to several million or more are found.

**crash**  A malfunction that brings work to a halt. A system crash usually is caused by a software malfunction, and ordinarily you can restart the system by rebooting the machine. A head crash, however, entails physical damage to a disk and probable data loss.

**CRC (cyclic redundancy checking)**  An error-detection technique consisting of a cyclic algorithm performed on each block or frame of data by both sending and receiving modems. The sending modem inserts the results of its computation in each data block in the form of a CRC code. The receiving modem compares its results with the received CRC code and responds with either a positive or negative acknowledgment. In the ARQ protocol implemented in high-speed modems, the receiving modem accepts no more data until a defective block is received correctly.

**crosstalk**  The electromagnetic coupling of a signal on one line with another nearby signal line. Crosstalk is caused by electromagnetic induction, where a signal traveling through a wire creates a magnetic field that induces a current in other nearby wires. Various methods including twisting wire pairs and placing ground wires between data wires are used to combat crosstalk and create more reliable data communications.

**CRT (cathode-ray tube)**  A term used to describe a television or monitor screen tube.

**current**  The flow of electrons, measured in amperes, or amps.

**cursor**  The small, flashing hyphen that appears onscreen to indicate the point at which any input from the keyboard will be placed.

**cycle**  Time for a signal to transition from one leading edge to the next leading edge.

**cyclic redundancy checking**  See CRC.

**cylinder**  The set of tracks on a disk that are on each side of all the disk platters in a stack and are the same distance from the center of the disk. The total number of tracks that can be read without moving the heads. A floppy drive with two heads usually has 160 tracks, which are accessible as 80 cylinders. A typical 120GB hard disk will physically have about 56,000 cylinders, 6 heads (3 platters), and an average of about 700 sectors per track, for a total of about 235,200,000 sectors (120.4GB).
Cyrix  Originally a Texas-based maker of Intel-compatible math coprocessor chips, Cyrix later developed low-cost, plug-compatible 6x86 and 6x86MX Pentium-class processors that were manufactured by IBM and other fabricators. Cyrix also developed the first chips with integrated audio and video (the MediaGX series). Cyrix was later absorbed into National Semiconductor, which retained the MediaGX technology when it sold Cyrix to VIA Technologies. VIA formerly developed and sold the VIA Cyrix MII, a low-cost Super Socket 7 processor, and currently sells and develops the C3, developed from the Cyrix “Joshua” processor. See also C3 and VIA Technologies.

D/A converter (DAC)  A device that converts digital signals to analog form. See also RAMDAC.

d-channel  In ISDN, a 16Kbps channel used to transmit control data about a connection.

daisy-chain  Stringing up components in such a manner that the signals move serially from one to the other. Most microcomputer multiple disk drive systems are daisy-chained. The SCSI bus system is a daisy-chain arrangement, in which the signals move from computer to disk drives to tape units, and so on. USB and IEEE-1394 devices also use the daisy-chain arrangement when hubs are used.

daisywheel printer  An impact printer that prints fully formed characters one at a time by rotating a circular print element composed of a series of individual spokes, each containing two characters that radiate from a center hub. Produces letter-quality output but has long been replaced by laser and LED printers.

DAT (digital audio tape)  A small cassette containing 4mm-wide tape used for storing large amounts of digital information. DAT technology emerged in Europe and Japan in 1986 as a way to produce high-quality, digital audio recordings and was modified in 1988 to conform to the digital data storage (DDS) standard for storing computer data. Raw/compressed capacities for a single tape are 2/4GB for DDS, 4/8GB for DDS-2, 12/24GB for DDS-3, and 20/40GB for DDS-4.

data  1) Groups of facts processed into information. A graphic or textural representation of facts, concepts, numbers, letters, symbols, or instructions used for communication or processing. 2) An android from the twenty-fourth century with a processing speed of 60 trillion operations per second and a storage capacity of 800 quadrillion bits, and who serves on the USS Enterprise NCC-1701-D with the rank of lieutenant commander.

data bus  The connection that transmits data between the processor and the rest of the system. The width of the data bus defines the number of data bits that can be moved into or out of the processor in one cycle.

data cable  Generically, a cable that carries data. Specific to HD connections, the narrower (20-pin) of two cables that connects an ST-506/412 or ESDI hard disk drive to a controller card.

data communications  A type of communication in which computers and terminals can exchange data over an electronic medium.

data compression  A technique in which mathematical algorithms are applied to the data in a file to eliminate redundancies and therefore reduce the size of the file. See also lossless compression and lossy compression.

Data Link Layer  In networking, the layer of the OSI reference model that controls how the electrical impulses enter or leave the network cable. Ethernet and Token-Ring are the two most common examples of Data Link Layer protocols. See also OSI.

data separator  A device that separates data and clock signals from a single encoded signal pattern. Usually, the same device performs both data separation and combination and is sometimes called an endec, or encoder/decoder.

data transfer rate  The maximum rate at which data can be transferred from one device to another.

daughterboard  Add-on board to increase functionality and/or memory. Attaches to the existing board.

DB-9  9-pin D-shell connector, primarily used for serial ports.

DB-25  25-pin D-shell connector, primarily used for PC parallel ports.

DC  Direct current, such as that provided by a power supply or batteries.

DC-600 (Data Cartridge 600)  A data-storage medium invented by 3M in 1971 that uses a 1/4"-wide tape 600 feet in length.

DCE (data communications equipment)  The hardware that performs communication—usually a dialup modem that establishes and controls the data link through the telephone network. See also DTE.

DDE (dynamic data exchange)  A form of interprocess communications used by Microsoft Windows to support the exchange of commands and data between two applications running simultaneously. This capability has been enhanced further with object linking and embedding (OLE).

DDOS (distributed denial of service)  Refers to a type of denial-of-service attack that uses multiple computers that have been taken over by an intruder to attack a targeted system. See also DoS.

DDR (double data rate)  A type of SDRAM that allows two accesses per clock cycle, doubling the effective speed of the memory. The most common types of DDR include PC2100 (also known as DDR 266MHz), PC2700 (also known as DDR 333MHz) and PC3200 (also known as DDR 400MHz). See also SDRAM.

**Appendix A**

---

**degauss**

1) To remove magnetic charges or to erase adjacent tracks. sectors so files are stored on consecutive sectors in The process of rearranging disk files is called defragmentation. A list of unusable sectors and tracks is called a defect map.

**de facto standard** A software or hardware technology not officially made a standard by any recognized standards organization but that is used as a reference for consumers and vendors because of its dominance in the marketplace.

**DEBUG** The name of a utility program included with DOS and used for specialized purposes, such as altering memory locations, tracing program execution, patching programs and disk sectors, and performing other low-level tasks.

**decibel (dB)** A logarithmic measure of the ratio between two powers, voltages, currents, sound intensities, and so on. Signal-to-noise ratios are expressed in decibels.

**dedicated line** A user-installed telephone line that connects a specified number of computers or terminals within a limited area, such as a single building. The line is a cable rather than a public-access telephone line. The communications channel also can be referred to as nonswitched because calls do not go through telephone company switching equipment.

**dedicated servo surface** In voice-coil-actuated hard disk drives, one side of one platter given over to servo data that is used to guide and position the read/write heads.

**default** Any setting assumed at startup or reset by the computer's software and attached devices and operational until changed by the user. An assumption the computer makes when no other parameters are specified. When you type DIR without specifying the drive to search, for example, the computer assumes you want it to search the default drive. The term is used in software to describe any action the computer or program takes on its own with embedded values.

**defect map** A list of unusable sectors and tracks coded onto a drive during the low-level format process.

**defragmentation** The process of rearranging disk sectors so files are stored on consecutive sectors in adjacent tracks.

**degauss** 1) To remove magnetic charges or to erase magnetic images. Normal applications include CRT monitors and disks or tapes. Most monitors incorporate a degaussing coil, which surrounds the CRT, and automatically energizes this coil for a few seconds when powered up to remove color or image distorting magnetic fields from the metal mask inside the tube. Some monitors include a button or control that can be used for additional applications of this coil to remove more stubborn magnetic traces. 2) Also the act of erasing or demagnetizing a magnetic disk or tape using a special tool called a degaussing coil.

**density** The amount of data that can be packed into a certain area on a specific storage media.

**desktop** A personal computer that sits on a desk.

**device driver** Originally, a memory-resident program loaded by CONFIG.SYS that controls an unusual device, such as an expanded memory board. Windows also uses device drivers, but they are loaded through the Windows Registry or .INI files.

**DHCP (Dynamic Host Configuration Protocol)** A protocol for assigning dynamic IP addresses to devices on a network. With dynamic addressing, a device can have a different IP address every time it connects to the network. Routers, gateways, and broadband modems can function as DHCP hosts to provide IP addresses to other computers and devices on the network.

**Dhrystone** A benchmark program used as a standard figure of merit indicating aspects of a computer system's performance in areas other than floating-point math performance. Because the program does not use any floating-point operations, performs no I/O, and makes no operating system calls, it is most useful for measuring the processor performance of a system. The original Dhrystone program was developed in 1984 and was written in Ada, although the C and Pascal versions became more popular by 1989.

**DHTML (Dynamic HTML)** A collective term for cascading style sheets, layering, dynamic fonts, and other features encompassed in standard HTML 4.0, Netscape Navigator 4.x and above, and Internet Explorer 4.x and above. Because of differences in how browsers interpret particular DHTML features, many developers incorporate browser-checking code into their Web pages to enable or disable certain features depending on the browser being used to view the page.

**diagnostics** Programs used to check the operation of a computer system. These programs enable the operator to check the entire system for any problems and indicate in which area the problems lie.

**dialup adapter** In Windows, a software program that uses a modem to emulate a network interface card for networking. Most commonly used to connect to an Internet service provider or a dialup server for remote access to a LAN.
**die**  An individual chip (processor, RAM, or other integrated circuit) cut from a finished silicon chip wafer and built into the physical package that connects it to the rest of the PC or a circuit board.

**differential**  An electrical signaling method in which a pair of lines are used for each signal in “push-pull” fashion. In most cases, differential signals are balanced so that the same current flows on each line in opposite directions. This is unlike single-ended signals, which use only one line per signal referenced to a single ground. Differential signals have a large tolerance for common-mode noise and little crosstalk when used with twisted-pair wires even in long cables. Differential signaling is expensive because two pins are required for each signal.

**digital camera**  A type of camera that uses a sensor and internal or removable flash memory in place of film to record still images. Digital cameras’ picture quality is usually rated in megapixels. See also megapixel.

**digital loopback**  A test that checks the modem’s RS-232 interface and the cable that connects the terminal or computer and the modem. The modem receives data (in the form of digital signals) from the computer or terminal and immediately returns the data to the screen for verification.

**digital signals**  Discrete, uniform signals. In this book, the term refers to the binary digits 0 and 1.

**digital signature**  An electronic identifier used to authenticate a message or the contents of a file. Windows 98 and above are designed to prefer digitally signed device drivers (drivers approved by the Windows Hardware Quality Labs) and will warn you if you try to install an unsigned device driver.

**digital-to-analog converter (DAC)**  A device for converting digital signals to analog signals. VGA-based displays are analog, so video cards that connect to them include a DAC to convert the signals to analog to drive the display.

**digitize**  To transform an analog wave to a digital signal a computer can store. Conversion to digital data and back is performed by a D/A converter (DAC), often a single-chip device. How closely a digitized sample represents an analog wave depends on the number of times the amplitude of a wave is measured and recorded (the rate of digitization), as well as the number of levels that can be specified at each instance. The number of possible signal levels is dictated by the resolution in bits.

**DIMM (dual inline memory module)**  A series of memory modules used in Pentium and newer PCs. They are available in many different versions, including those with SDRAM, DDR or DDR2, 3.3V, 2.5V or 1.8V, buffered, unbuffered or registered, and in 64-bit (non-ECC/parity) or 72-bit (ECC/parity) form. See also DDR, DDR2, and SDRAM.

**DIP (dual inline package)**  A family of rectangular, integrated-circuit flat packages that have leads on the two longer sides. Package material is plastic or ceramic.

**DIP switch**  A tiny switch (or group of switches) on a circuit board. Named for the form factor of the carrier device in which the switch is housed.

**direct memory access (DMA)**  A process by which data moves between a disk drive (or other device) and system memory without direct control of the central processing unit, thus freeing it up for other tasks.

**Direct Rambus DRAM**  See RDRAM.

**directory**  An area of a disk that stores the titles given to the files saved on the disk and serves as a table of contents for those files. Contains data that identifies the name of a file, the size, the attributes (system, hidden, read-only, and so on), the date and time of creation, and a pointer to the location of the file. Each entry in a directory is 32 bytes long. Windows refers to subdirectories (directories beneath the root directory) as folders.

**DirectX**  A set of graphics-related drivers and APIs that translates generic hardware commands into specific commands for particular pieces of hardware. Developed by Microsoft, DirectX lets graphical or multimedia applications take advantage of specific features supported by various graphics accelerators.

**disk**  Flat, circular, rotating medium that can store various types of information, both analog and digital. *Disc* is often used in reference to optical storage media, whereas *disk* refers to magnetic storage media. *Disc* also is often used as a short form for videodisc or compact audio disc (CD).

**disk access**  See access time.

**disk cache**  A portion of memory on the PC motherboard or on a drive interface card or controller used to store frequently accessed information from the drive (such as the file allocation table [FAT] or directory structure) to speed up disk access. With a larger disk cache, additional data from the data portion of a drive can be cached as well. See also cache, L1 cache, and L2 cache.

**disk partition**  See partition.

**display**  A device used for viewing information generated by a computer.

**display adapter**  The interface between the computer and the monitor that transmits the signals which appear as images on the display. This can take the form of an expansion card or a chip built into the motherboard.
An Internet attack on a DoS (denial of service) facturing of electronic chips.

Doping: Adding chemical impurities to silicon (which is naturally a nonconductor) to create a material with semiconductor properties that is then used in the manufacturing of electronic chips.

DoS (denial of service): An Internet attack on a resource that prevents users from accessing email, Web sites, or other services. It usually exploits security shortcomings in email or Web servers. See also DDoS.

DOS (Disk Operating System): A collection of programs stored on the DOS disk that contain routines enabling the system and user to manage information and the hardware resources of the computer. DOS must be loaded into the computer before other programs can be started.

dot pitch: A measurement of the width of the dots that make up a pixel. The smaller the dot pitch, the sharper the image.

dot-matrix printer: An impact printer that prints characters composed of dots. Characters are printed one at a time by pressing the ends of selected wires against an inked ribbon and paper.

double density (DD): An indication of the storage capacity of a floppy drive or disk in which eight or nine sectors per track are recorded using MFM encoding. See also MFM encoding.

download: The process of receiving files from another computer.

downtime: Operating time lost because of a computer malfunction.

DMI (DOS Protected Mode Interface): An industry-standard interface that allows DOS applications to execute program code in the protected mode of the 286 or later Intel processor. The DPMI specification is available from Intel.

DPMS (Display Power Management Signaling): A VESA standard for signaling a monitor or display to switch into energy conservation mode. DPMS provides for two low-energy modes: standby and suspend.

DRAM (dynamic random access memory): The most common type of computer memory, DRAM can be manufactured very inexpensively compared to other types of memory. DRAM chips are small and inexpensive because they normally require only one transistor and a capacitor to represent each bit. The capacitors must be energized every 15ms or so (hundreds of times per second) to maintain their charges. DRAM is volatile, meaning it loses data with no power or without regular refresh cycles.

driver: A mechanical device that manipulates data storage media.

drum: The cylindrical photoreceptor in a laser printer that receives the document image from the laser and applies it to the page as it slowly rotates.

DSL (digital subscriber line): A high-speed digital modem technology. DSL is either symmetric or asymmetric. Asymmetric provides faster downstream speeds, which is suited for Internet usage and video on demand. Symmetric provides the same rate coming and going. See also ADSL.

DSM (digital storage media): A digital storage or transmission device or system.

DSP (digital signal processor): Dedicated, limited-function signal processor often found in modems, sound cards, cellular phones, and so on.
DTE (data terminal [or terminating] equipment)  The device, usually a computer or terminal, that generates or is the final destination of data. See also DCE.

dual cavity pin grid array  Chip packaging designed by Intel for use with the Pentium Pro processor that houses the processor die in one cavity of the package and the L2 cache memory in a second cavity within the same package.

dual independent bus (DIB) architecture  A processor technology with the existence of two independent buses on the processor—the L2 cache bus and the processor-to-main memory system bus. The processor can use both buses simultaneously, thus getting as much as two times more data into and out of the processor than a single bus architecture processor. The Intel Pentium Pro, Pentium II, and newer processors from Intel and AMD (such as the AMD Athlon and Duron) have DIB architecture.

dual scan display  A lower-quality but economical type of LCD color display that has an array of transistors running down the x and y axes of two sides of the screen. The number of transistors determines the screen’s resolution.

dumb terminal  A screen and keyboard device with no inherent processing power connected to a computer that is usually remotely located.

duplex  Indicates a communications channel capable of carrying signals in both directions.

Duron  A low-cost version of the Athlon processor with less L2 cache. Available in the Socket A (462-pin) chip package.

DVD (digital versatile disc)  Originally called Digital Video Disc and Drive formats. A new type of high-capacity CD-ROM disc and drive format with up to 28 times the capacity of a standard CD-ROM. The disc is the same diameter as a CD-ROM but can be recorded on both sides and on two layers for each side. Each side holds 4.7GB on a single layer disc, whereas dual-layer versions hold 8.5GB per side, for a maximum of 17GB total if both sides and both layers are used, which is the equivalent of 28 CD-ROMs. DVD drives can read standard audio CDs and CD-ROMs.

DVD burner  Popular term for a rewritable DVD drive, particularly one that uses DVD-R/RW or DVD+R/RW media.

DVD-A  A DVD format designed to support high-quality music and audio. DVD-A uses 24-bit sampling at 96KHz, significantly better than CD audio (16-bit at 44.1KHz). Unlike DVD, DVD-A discs can be played on conventional CD players but produce the highest quality only when played on DVD-A players.

DVD-R  A writeable DVD format compatible with standalone DVD players and DVD-ROM drives. DVD-R was introduced by Pioneer and was released to the DVD Forum (www.dvdforum.org) in July 1997. It uses a wobbled-groove recording process to store 4.7GB of data and is optimized for sequential data access. See also DVD-RW.

DVD+R  A writeable DVD format compatible with standalone DVD players and DVD-ROM drives. DVD+R was developed by the DVD+RW Alliance (www.dvd+rw.com), whose members include Microsoft, Sony, HP, and Dell. In addition, it is supported by second-generation DVD+RW drives and holds 4.7GB of data. DVD+R/RW are the only recordable DVD formats that fully support the Mt. Rainier (also called EasyWrite) standard coming in Windows Longhorn (in 2005). This enables discs to be used right out of the box with automatic background formatting and no additional packet writing software required. DVD+R/RW are the most compatible, fastest, most capable, and most popular of all the recordable DVD formats. See also DVD+RW.

DVD-RAM  A rewritable DVD format developed by Panasonic, Toshiba, and Hitachi and supported by the DVD Forum. DVD-RAM is the oldest DVD rewritable format, but because the media uses a caddy and has a lower reflectivity than normal DVD media, DVD-RAM discs are not compatible with other types of DVD drives or with standalone DVD players.

DVD-RW  A rewritable DVD format developed by Pioneer and released to the DVD Forum in November 1999. It uses a phase-change technology similar to CD-RW. As with most CD-RW media and drives, the entire disc must be formatted before it can be used. Its write speed is also lower than DVD+RW, and the entire disc must be erased before it can be used to store new data. See also DVD-R.

DVD+RW  A rewritable DVD format developed by the DVD+RW Alliance; the first DVD+RW drives were released in 2001. DVD+RW uses a phase-change technology similar to CD-RW and DVD-RW. DVD+R/RW are the only recordable DVD formats that fully support the Mt. Rainier (EasyWrite) standard coming in Windows Longhorn (in 2005). This enables discs to be used right out of the box with automatic background formatting and no additional packet writing software required. DVD+R/RW are the most compatible, fastest, most capable, and most popular of all the recordable DVD formats. See also DVD+R.

DVI (Digital Video Interactive)  A standard that was originally developed at RCA Laboratories and sold to Intel in 1988. DVI integrates digital motion, still video, sound, graphics, and special effects in a compressed format. DVI is a highly sophisticated hardware compression technique used in interactive multimedia applications.
DVI (Digital Visual Interface) The current de facto standard for LCD displays developed by the Digital Display Working Group in April 1999. DVI-D provides digital signals only, whereas DVI-I (which is more common) provides both digital and analog signals. A DVI-I connector can be converted to VGA with an external adapter.

Dvorak keyboard A keyboard design by August Dvorak that was patented in 1936 and approved by ANSI in 1982. Provides increased speed and comfort and reduces the rate of errors by placing the most frequently used letters in the center for use by the strongest fingers. Finger motions and awkward strokes are reduced by more than 90% in comparison with the familiar QWERTY keyboard. The Dvorak keyboard has the five vowel keys, AOEUI, together under the left hand in the center row and the five most frequently used consonants, DHTNS, under the fingers of the right hand.

dynamic execution A processing technique that enables the processor to dynamically predict the order of instructions and execute them out of order internally if necessary for an improvement in speed. Uses these three techniques: Multiple Branch Prediction, Data Flow Analysis, and Speculative Execution.

E2000 Also called Energy 2000, this is a Swiss-developed standard for power management that calls for computer monitors to use only 5 watts of power when in standby mode.

EBCDIC (Extended Binary Coded Decimal Interchange Code) An IBM-developed, 8-bit code for the representation of characters. It allows 256 possible character combinations within a single byte. EBCDIC is the standard code on IBM minicomputers and mainframes, but not on the IBM microcomputers, where ASCII is used instead.

ECC (error correcting code) A type of system memory or cache that is capable of detecting and correcting some types of memory errors without interrupting processing.

ECP (enhanced capabilities port) A type of high-speed parallel port jointly developed by Microsoft and Hewlett-Packard that offers improved performance for the parallel port and requires special hardware logic. ECP ports use both an IRQ and a DMA channel. See also IEEE 1284.

edge connector The part of a circuit board containing a series of printed contacts that is inserted into an expansion slot or a connector.

EDO (extended data out) RAM A type of RAM chip that enables a timing overlap between successive accesses, thus improving memory cycle time.

EEPROM (electrically erasable programmable read-only memory) A type of nonvolatile memory chip used to store semipermanent information in a computer, such as the BIOS. An EEPROM can be erased and reprogrammed directly in the host system without special equipment. This is used so manufacturers can upgrade the ROM code in a system by supplying a special program that erases and reprograms the EEPROM chip with the new code. Also called flash ROM.

EGA (enhanced graphics adapter) A type of PC video display adapter first introduced by IBM on September 10, 1984, that supports text and graphics. Text is supported at a maximum resolution of 80x25 characters in 16 colors with a character box of 8x14 pixels. Graphics are supported at a maximum resolution of 640x350 pixels in 16 (from a palette of 64) colors. The EGA outputs a TTL (digital) signal with a horizontal scanning frequency of 15.75KHz, 18.432KHz, or 21.85KHz, and it supports TTL color or TTL monochrome displays.

EIA (Electronic Industries Association) An organization that defines electronic standards in the United States.

EIDE (Enhanced Integrated Drive Electronics) A specific Western Digital implementation of the ATA-2 specification. See also ATA-2.

EISA (Extended Industry Standard Architecture) An extension of the Industry Standard Architecture (ISA) bus developed by IBM for AT and Zenith. The first EISA board was IBM's Micro Channel Architecture (MCA) in the PS/2 systems, but unlike MCA, EISA enables backward compatibility with older plug-in adapters. EISA products became obsolete after the development of the PCI slot architecture. See also PCI.

electronic mail (email) A method of transferring messages from one computer to another.

electrostatic discharge (ESD) The grounding of static electricity. A sudden flow of electricity between two objects at different electrical potentials. ESD is a primary cause of integrated circuit damage or failure.

ELF (extremely low frequency) A very low-frequency electromagnetic radiation generated by common electrical appliances, including computer monitors. The Swedish MPR II standard governs this and other emissions. Also called VLF (very low frequency).

embedded controller In disk drives, a controller built into the same physical unit that houses the drive rather than on a separate adapter card. IDE and SCSI drives both use embedded controllers.
embedded servo data  Magnetic markings embedded between or inside tracks on disk drives that use voice-coil actuators. These markings enable the actuator to fine-tune the position of the read/write heads.

EMM (expanded memory manager)  A driver that provides a software interface to expanded memory. EMMs were originally created for expanded memory boards but also can use the memory management capabilities of the 386 or later processors to emulate an expanded memory board. EMM386.EXE is an example of an EMM that comes with DOS and Windows 9x.

EMS (Expanded Memory Specification)  Sometimes also called the LIM spec because it was developed by Lotus, Intel, and Microsoft. Provides a way for microcomputers running under DOS to access additional memory. EMS memory management provides access to a maximum of 32MB of expanded memory through a small (usually 64KB) window in conventional memory. EMS is a cumbersome access scheme designed primarily for pre-286 systems that could not access extended memory.

dumulator  A piece of test apparatus that emulates or imitates the function of a particular chip.

encoding  The protocol by which data is carried or stored by a medium.

encryption  The translation of data into unreadable codes to maintain security.

endec (encoder/decoder)  A device that takes data and clock signals and combines or encodes them using a particular encoding scheme into a single signal for transmission or storage. The same device also later separates or decodes the data and clock signals during a receive or read operation. Sometimes called a data separator.

Energy Star  A certification program started by the Environmental Protection Agency. Energy Star certifies computers and peripherals are designed to draw less than 30 watts of electrical energy from a standard 110-volt AC outlet during periods of inactivity. Also referred to as Green PCs. See also E2000.

Enhanced CD (CD-E)  See Blue Book.

enhanced graphics adapter  See EGA.

enhanced small device interface  See ESDI.

EPP (enhanced parallel port)  A type of parallel port developed by Intel, Xircom, and Zenith Data Systems that operates at almost ISA bus speed and offers a tenfold increase in the raw throughput capability over a conventional parallel port. EPP is especially designed for parallel port peripherals, such as LAN adapters, disk drives, and tape backups. See also IEEE 1284.

EPROM (erasable programmable read-only memory)  A type of read-only memory (ROM) in which the data pattern can be erased to allow a new pattern. EPROM usually is erased by ultraviolet light and recorded by a higher-than-normal voltage programming signal.

equalization  A compensation circuit designed into modems to counteract certain distortions introduced by the telephone channel. Two types are used: fixed (compromise) equalizers and those that adapt to channel conditions (adaptive). Good-quality modems use adaptive equalization.

error control  Various techniques that check the reliability of characters (parity) or blocks of data. V.42, MNP, and HST error-control protocols use error detection (CRC) and retransmission of error frames (ARQ).

error message  A word or combination of words to indicate to the user that an error has occurred somewhere in the program.

ESCD (extended system configuration data)  Area in CMOS or Flash/NVRAM where plug-and-play information is stored.

ESDI (Enhanced Small Device Interface)  A hardware standard developed by Maxtor and standardized by a consortium of 22 disk drive manufacturers on January 26, 1983. A group of 27 manufacturers formed the ESDI steering committee on September 15, 1986, to enhance and improve the specification. A high-performance interface used primarily with hard disks, ESDI enables a maximum data transfer rate to and from a hard disk of between 10Mbps and 24Mbps. ESDI was replaced by IDE and SCSI interfaces. ESDI drives use the same 34-pin and 20-pin cables used by ST412/ST506 drives.

Ethernet  A type of network protocol developed in the late 1970s by Bob Metcalf at Xerox Corporation and endorsed by the IEEE. One of the oldest LAN communications protocols in the personal computing industry, Ethernet networks use a collision-detection protocol to manage contention. Ethernet is defined by the IEEE 802.3 standard. See also 10BASE-T.

expanded memory  Otherwise known as EMS memory, this is memory that conforms to the EMS specification. Requires a special device driver and conforms to a standard developed by Lotus, Intel, and Microsoft.

expansion card  An integrated circuit card that plugs into an expansion slot on a motherboard to provide access to additional peripherals or features not built into the motherboard. Also referred to as an add-in board.

expansion slot  A slot on the motherboard that physically and electrically connects an expansion card to the motherboard and the system busses.

extended graphics array  See XGA.

extended memory  Direct processor-addressable memory addressed by an Intel (or compatible) 286 or more advanced processor in the region beyond the first megabyte. Addressable only in the processor’s protected mode of operation.
extended partition A nonbootable DOS partition (also supported by Windows) containing DOS volumes. Starting with DOS v3.3, the FDISK program can create two partitions that serve DOS: an ordinary, bootable partition (called the primary partition) and an extended partition, which can contain as many as 23 volumes from D: to Z:

external device A peripheral installed outside the system case.

extra-high density (ED) An indication of the storage capacity of a floppy drive or disk in which 36 sectors per track are recorded using a vertical recording technique with MFM encoding.

FAQ (frequently asked questions) Name for a list of popular questions and answers covering any particular subject.

Fast Ethernet Popular term for 100BASE-T and other 100Mbps versions of Ethernet. Fast Ethernet uses CAT 5 cable.

Fast Page Mode RAM A type of RAM that improves on standard DRAM speed by enabling faster access to all the data within a given row of memory by keeping the row address the same and changing only the column.

Fast-ATA (fast AT attachment interface) Also called Fast ATA-2, these are specific Seagate and Quantum implementations of the ATA-2 interface. See also ATA-2.

FAT (file allocation table) A table held near the outer edge of a disk that tells which sectors are allocated to each file and in what order.

FAT32 A disk file allocation system from Microsoft that uses 32-bit values for FAT entries instead of the 16-bit values used by the original FAT system, enabling partition sizes up to 2TB (terabytes). Although the entries are 32-bits, 4-bits are reserved and only 28-bits are used. FAT32 first appeared in Windows 95B and is also supported by Windows 98, Windows Me, Windows 2000, and Windows XP.

fault tolerance The capability of a computer to withstand a failure. Many levels of fault tolerance exist, and fault tolerance can be applied to several components or systems in the computer. For example, ECC (error correcting code) memory is considered fault tolerant because it is typically capable of automatically identifying and correcting single bit errors.

fax/modem A peripheral that integrates the capabilities of a fax machine and a modem in one expansion card or external unit. Almost all 14.4kbs and faster modems sold for use in desktop or portable PCs include fax capabilities.

FC-PGA (flip-chip pin grid array) A type of chip packaging first used in the Socket PGA370 version of the Pentium III where the raw processor die has bumped contacts spaced on the face of the die and is mounted face-down to a pin grid array carrier. The heat sink is then directly attached to the back of the raw silicon die surface.

FDISK The name of the disk-partitioning program under several operating systems, including DOS and Windows 9x/Me, to create the master boot record and allocate partitions for the operating system's use.

feature connector On a video adapter, a connector that enables an additional video feature card, such as a separate 3D accelerator, video capture card, or MPEG decoder, to be connected to the main video adapter and display.

fiber optic A type of cable or connection using strands or threads of glass to guide a beam of modulated light. Allows for very high-speed signaling and multiplexing as well as the combining of many data streams along a single cable.

FIFO (first-in, first-out) A method of storing and retrieving items from a list, table, or stack so that the first element stored is the first one retrieved.

file A collection of information kept somewhere other than in random-access memory.

file attribute Information held in the attribute byte of a file's directory entry.

file compression See compressed file.

filename The name given to the disk file. For DOS, it must be from one to eight characters long and can be followed by a filename extension, which can be from one to three characters long. Windows 9x and above ease these constraints by allowing filenames of up to 255 characters including the directory path.

firewall A hardware or software system designed to prevent unauthorized access to or from a private network.

FireWire Also called IEEE-1394 or i.Link. A serial I/O interface standard that is extremely fast, with data transfer rates up to 400Mbps, 800Mbps, or 3.2Gbps, depending on the version of standard used. Most current implementations use the 400Mbps IEEE-1394a version.

firmware Software contained in a read-only memory (ROM) device. A cross between hardware and software, firmware can be easily updated if stored in an EEPROM or flash ROM chip. See also EEPROM and flash ROM.

fixed disk Also called a hard disk, it's a disk that can't be removed from its controlling hardware or housing. Made of rigid material with a magnetic coating and used for the mass storage and retrieval of data.

flash ROM A type of EEPROM developed by Intel that can be erased and reprogrammed in the host system. See also EEPROM.

flicker A monitor condition caused by refresh rates that are too low, in which the display flashes visibly. This can cause eyestrain or more severe physical problems.

floating-point unit (FPU) Sometimes called the math coprocessor; handles the more complex calculations of the processing cycle.
floppy disk  A removable disk using flexible magnetic media enclosed in a semirigid or rigid plastic case.

floppy disk controller  The logic and interface that connects a floppy disk drive to the system.

floppy tape  A tape standard that uses drives connecting to an ordinary floppy disk controller, such as QIC-80 or Travan-1.

floptical drive  A special type of high-capacity removable disk drive that uses an optical mechanism to properly position the drive read/write heads over the data tracks on the disk. This enables more precise control of the read/write positioning and therefore narrower track spacing and more data packed into a smaller area than traditional floppy disks. The LS-120 and LS-240 SuperDisk drives are recent examples of floptical drives.

flow control  A mechanism that compensates for differences in the flow of data input to and output from a modem or other device.

FM encoding  Frequency modulation encoding. An outdated method of encoding data on the disk surface that uses up half the disk space with timing signals.

FM synthesis  An audio technology that uses one sine wave operator to modify another and create an artificial sound that mimics an instrument.

folder  In a graphical user interface, a simulated file folder that holds documents (text, data, or graphics), applications, and other folders. A folder is similar to a DOS subdirectory.

footprint  Describes the shape of something. See also form factor.

form factor  The physical dimensions of a device. Two devices with the same form factor are physically interchangeable. The IBM PC, XT, and XT Model 286, for example, all use power supplies that are internally different but have exactly the same form factor.

FORMAT  The DOS/Windows format program that performs both low- and high-level formatting on floppy disks but only high-level formatting on hard disks.

formatted capacity  The total number of bytes of data that can fit on a formatted disk. The unformatted capacity is higher because space is lost defining the boundaries between sectors.

formatting  Preparing a disk so the computer can read or write to it. Checks the disk for defects and constructs an organizational system to manage information on the disk.

FORTRAN (formula translator)  A high-level programming language developed in 1954 by John Backus at IBM primarily for programs dealing with mathematical formulas and expressions similar to algebra and used primarily in scientific and technical applications.

fragmentation  The state of having a file scattered around a disk in pieces rather than existing in one contiguous area of the disk. Fragmented files are slower to read than files stored in contiguous areas and can be more difficult to recover if the FAT or a directory becomes damaged.

frame  1) A data communications term for a block of data with header and trailer information attached. The added information usually includes a frame number, block size data, error-check codes, and start/end indicators. 2) A single, complete picture in a video or film recording. A video frame consists of two interlaced fields of either 525 lines (NTSC) or 625 lines (PAL/SECAM), running at 30 frames per second (NTSC) or 25 frames per second (PAL/SECAM).

frame buffer  A memory device that stores, pixel by pixel, the contents of an image. Frame buffers are used to refresh a raster image. Sometimes they incorporate local processing capability. The “depth” of the frame buffer is the number of bits per pixel, which determines the number of colors or intensities that can be displayed.

frame rate  The speed at which video frames are scanned or displayed: 30 frames per second for NTSC and 25 frames per second for PAL/SECAM.

FTP (File Transfer Protocol)  A method of transferring files over the Internet. FTP can be used to transfer files between two machines on which the user has accounts. Anonymous FTP can be used to retrieve a file from a server without having an account on that server.

full duplex  Signal flow in both directions at the same time. In microcomputer communications, it also can refer to the suppression of the online local echo. 100BASE-TX network cards capable of full-duplex operations can run at an effective speed of 200Mbps when full-duplex operation is enabled.

full-height drive  A drive unit that is 3 1/4" high, 5 1/4" wide, and 8" deep. Equal to two half-height drive bays.

full-motion video  A video sequence displayed at full television standard resolutions and frame rates. In the U.S., this equates to NTSC video at 30 frames per second.

function keys  Special-purpose keys that can be programmed to perform various operations. They serve many functions, depending on the program being used.

G.lite  A popular form of ADSL, G.lite can be self-installed by the user. Also referred to as the G.992.2 standard.

gas-plasma display  Commonly used in portable systems, it’s a type of display that operates by exciting a gas—usually neon or an argon-neon mixture—through the application of a voltage. When sufficient voltage is applied at the intersection of two electrodes, the gas glows an orange-red. Because gas-plasma displays generate light, they require no backlighting.
gateway  Officially, an application-to-application conversion program or system. For example, an email gateway converts from SMTP (Internet) email format to MHS (Novell) email format. The term gateway is also used as a slang term for router. See also router.
gender  When describing connectors for PCs, connectors are described as male if they have pins or female if they have receptacles designed to accept the pins of a male connector.
genlocking  The process of aligning the data rate of a video image with that of a digital device to digitize the image and enter it into computer memory. The machine that performs this function is known as a genlock.
Ghost  Popular utility program sold by Symantec that can be used to create a compressed version of a drive's contents and clone it to one or more PCs over a network or via CD storage.
gibi  A multiplier equal to 1,073,741,824.
gibibyte (Gi)  A unit of information storage equal to 1,073,741,824 bytes (1,024×1,024×1,024 equals a Gi). Formerly known as a binary gigabyte. See also gigabyte and kilobyte.
GIF (Graphics Interchange Format)  A popular raster graphics file format developed by CompuServe that handles 8-bit color (256 colors) and uses the LZW method to achieve compression ratios of approximately 1.5:1 to 2:1. You can reduce the size of a GIF file even more by dropping unused colors from the file.
giga  A multiplier indicating one billion (1,000,000,000) of some unit. Abbreviated as g or G. The binary giga (1,073,741,824) is now referred to as a gib. See also gibi.
gigabyte (GB)  A unit of information storage equal to 1,000,000,000 bytes. The value formerly called a binary GB (1,073,741,824 bytes) is now called a gibibyte. See also gibibyte.
gigahertz  GHz is used to measure the clock frequency of high-performance processors. The first 1GHz desktop processor was introduced by AMD (a 1GHz Athlon) in March 2000.
GPU (graphics processing unit)  A 3D graphics chip that contains advanced 3D rendering features such as hardware, vertex, and pixel shaders. NVIDIA's GeForce 3 and GeForce 4 Ti series; the ATI Radeon 7xxx, 8xxx, and 9xxx series; and the Matrox Parhelia series are typical GPUs. See also hardware shader, pixel shader, and vertex shader.
graphics accelerator  A video processor or chipset specially designed to speed the display and rendering of graphical objects onscreen. Originally, accelerators were optimized for 2D or 3D operations, but all current graphics accelerators, such as NVIDIA's GeForce and ATI's RADEON series, accelerate both types of data.
graffics adapter  See video adapter.
Green Book  The standard for Compact Disc-Interactive (CD-I). Philips developed CD-I technology for the consumer market to be connected to an additional computer monitor. CD-I is not a computer system but a consumer device that made a small splash in the market and disappeared. CD-I discs require special code and are not compatible with standard CD-ROMs. A CD-ROM can't be played on the CD-I machine, but Red Book audio can be played on it.
GUI (graphical user interface)  A type of program interface that enables users to choose commands and functions by pointing to a graphical icon using either a keyboard or pointing device, such as a mouse. Windows is the most popular GUI available for PC systems.
half duplex  Signal flow in both directions but only one way at a time. In microcomputer communications, half duplex can refer to activation of the online local echo, which causes the modem to send a copy of the transmitted data to the screen of the sending computer.
half-height drive  A drive unit that is 1.625” high, 5 1/4” wide, and 8” deep.
halftoning  A process that uses dithering to simulate a continuous tone image, such as a photograph or shaded drawing, using various sizes of dots. Newspapers, magazines, and many books use halftoning. The human eye merges the dots to give the impression of gray shades.
handshaking  The process of exchanging information about speeds and protocols between analog modems to establish a dialup connection. If your modem volume is high enough, you can hear handshaking as a series of distinct tones at the start of a modem-to-modem call.
hard disk  A high-capacity disk storage unit characterized by a normally nonremovable rigid substrate medium. The platters in a hard disk usually are constructed of aluminum or glass/ceramic. Also sometimes called a fixed disk.
hard error  An error in reading or writing data caused by damaged hardware.
hard reset  Resetting a system via the hardware, usually by pressing a dedicated reset button wired to the motherboard/processor reset circuitry. Does not clear memory like a cold boot does. See also cold boot.
hardware  Physical components that make up a microcomputer, monitor, printer, and so on.
hardware shader  A general term describing the processing of vertex or pixel shading in a GPU's hardware. GPUs such as the ATI 8xxx and 9xxx series or the NVIDIA GeForce 3 and GeForce 4 Ti-series GPU chips have hardware shaders compatible with DirectX 8 and above.
**HDLC (High-Level Data Link Control)** A standard protocol developed by the ISO for software applications and communicating devices operating in synchronous environments. Defines operations at the link level of communications—for example, the format of data frames exchanged between modems over a phone line.

**head** A small electromagnetic device inside a drive that reads, records, and erases data on the media.

**head actuator** The device that moves read/write heads across a disk drive’s platters. Most drives use a stepper-motor or voice-coil actuator.

**head crash** A (usually) rare occurrence in which a read/write head strikes a platter surface with sufficient force to damage the magnetic medium.

**head parking** A procedure in which a disk drive’s read/write heads are moved to an unused track so they will not damage data in the event of a head crash or other failure.

**head seek** The movement of a drive’s read/write heads to a particular track.

**heatsink** A mass of metal attached to a chip carrier or socket for the purpose of dissipating heat. Some heatsinks are passive (relying on existing air currents only), but most heatsinks on processors are active (including a fan). Many video card accelerator chips and motherboard North Bridge chips are also fitted with heatsinks today.

**helical scan** A type of recording technology that has vastly increased the capacity of tape drives. Invented for use in broadcast systems and now used in VCRs. Conventional longitudinal recording records a track of data straight across the width of a single-track tape. Helical scan recording packs more data on the tape by positioning the tape at an angle to the recording heads. The heads spin to record diagonal stripes of information on the tape. Helical scan is used by DAT/DDS, Exabyte, and AIT drives.

**hexadecimal number** A number encoded in base-16, such that digits include the letters A–F and the numerals 0–9 (for example, 8BF3, which equals 35,827 in base-10).

**hidden file** A file not displayed in DOS directory listings because the file’s attribute byte holds a special setting.

**high density (HD)** An indication of the storage capacity of a floppy drive or disk, in which 15 or 18 sectors per track are recorded using MFM encoding.

**High Sierra format** A standard format for placing files and directories on CD-ROMs, proposed by an ad hoc committee of computer vendors, software developers, and CD-ROM system integrators. (Work on the format proposal began at the High Sierra Hotel in Lake Tahoe, Nevada.) A revised version of the format was adopted by the ISO as ISO 9660. Use the ISO 9660 format to create cross-platform CD-R recordings.

**high-definition television (HDTV)** Video formats offering greater visual accuracy (or resolution) than current NTSC, PAL, or SECAM broadcast standards. HDTV formats generally range in resolution from 655 to 2,125 scanning lines, having an aspect ratio of 5:3 (or 1.67:1) and a video bandwidth of 30MHz–50MHz (5+ times greater than the NTSC standard). Digital HDTV has a bandwidth of 300MHz. HDTV is subjectively comparable to 35mm film.

**high-level formatting** Formatting performed by the DOS FORMAT program. Among other things, it creates the root directory and FATs.

**history file** A file created by utility software to keep track of earlier use of the software. Many backup programs, for example, keep history files describing earlier backup sessions.

**hit ratio** In describing the efficiency of a disk or memory cache, the hit ratio is the ratio of the number of times the data is found in the cache to the total number of data requests. 1:1 is a perfect hit ratio, meaning that every data request was found in the cache. The closer to 1:1 the ratio is, the more efficient the cache.

**HMA (high memory area)** The first 64KB of extended memory, which typically is controlled by the HIMEM.SYS device driver. Real-mode programs can be loaded into the HMA to conserve conventional memory. Normally, DOS 5.0 and later use the HMA exclusively to reduce the DOS conventional memory footprint.

**HomePNA** A home networking standard using existing home or office telephone wiring to obtain speeds up to 11Mbps.

**HomeRF** A wireless home network using radio waves to obtain speeds up to 11Mbps.

**horizontal scan rate** In monitors, the speed at which the electron beam moves laterally across the screen. It’s normally expressed as a frequency; typical monitors range from 31.5KHz to 90KHz, with the higher frequencies being more desirable.

**host** The main device when two or more devices are connected. When two or more systems are connected, the system that contains the data is typically called the host, whereas the other is called the guest or user.

**hotfix** A software patch for a Microsoft application or operating system. Hotfixes can be downloaded individually from the Windows Update Web site or as a service pack. Microsoft also calls them quick fix engineering (QFE) files.

**HPT (high-pressure tin)** A PLCC socket that promotes high forces between socket contacts and PLCC contacts for a good connection.

**HST (High-Speed Technology)** The now-obsolete U.S. Robotics proprietary high-speed modem-signaling scheme, developed as an interim protocol until the V.32 protocol could be implemented in a cost-effective manner.
HT technology  See hyper-threading technology.

HTML (Hypertext Markup Language)  A language used to describe and format plain-text files on the Web. HTML is based on pairs of tags that enable the user to mix graphics with text, change the appearance of text, and create hypertext documents with links to other documents. See also DHTML.

HTTP (Hypertext Transfer Protocol)  The protocol that describes the rules a browser and server use to communicate over the World Wide Web. HTTP allows a Web browser to request HTML documents from a Web server. See also DHTML.

hub  A common connection point for multiple devices in a network. A hub contains a number of ports to connect several segments of a LAN together. When a packet arrives at one of the ports on the hub, it is copied to all the other ports so all the segments of the LAN can see all the packets. A hub can be passive, intelligent (allowing remote management, including traffic monitoring and port configuration), or switching. A switching hub is also called a switch. See also switch.

Huffman coding  A technique that minimizes the average number of bytes required to represent the characters in a text. Huffman coding works for a given character distribution by assigning short codes to frequently occurring characters and longer codes to infrequently occurring characters.

hybrid fiber coaxial (HFC)  A network (such as that used by digital cable TV and two-way cable modems) that uses fiber-optic cabling for its backbone with coaxial cable connections to each individual computer or TV.

hyper-threading technology  A method (also called HT technology) developed by Intel for running two different instruction streams through a processor at the same time. Introduced in 2002, HT technology was first used in the Intel Xeon processor with hyper-threading technology, with speeds starting at 2.8GHz; the first HT technology–enabled desktop processor was the 3.06GHz Pentium 4.

hypertext  A technology that enables quick and easy navigation between and within large documents. Hypertext links are pointers to other sections within the same document; other documents; or other resources, such as FTP sites, images, or sounds.

HyperTransport  AMD’s high-speed technology for connecting the North Bridge and South Bridge or equivalent chips on a motherboard. HyperTransport runs at six times the speed of the PCI bus (800MBps versus 133MBps for PCI). The original name was Lightning Data Transport (LDT). Several chipset makers, including AMD and NVIDIA, use HyperTransport.

Hz  An abbreviation for hertz—a frequency measurement unit used internationally to indicate one cycle per second.

i.Link  Sony’s term for IEEE 1394/FireWire port. See also FireWire.

I/O (input/output)  A circuit path that enables independent communication between the processor and external devices.

I/O controller hub  See ICH.

I/O port (input/output port)  Used to communicate to and from another device, such as a printer or disk.

IA-64  Intel’s 64-bit processor architecture, first used in the Itanium processor for servers.

IBMIBIO.COM  One of the DOS system files required to boot the machine in older versions of PC-DOS (IBM’s version of MS-DOS). The first file loaded from disk during the boot, it contains extensions to the ROM BIOS.

IBMDFS.COM  One of the DOS system files required to boot the machine in older versions of PC-DOS (IBM’s version of MS-DOS). Contains the primary DOS routines. Loaded by IBMIBIO.COM, it in turn loads COMMAND.COM.

IC (integrated circuit)  A complete electronic circuit contained on a single chip. It can consist of only a few or thousands of transistors, capacitors, diodes, or resistors, and it generally is classified according to the complexity of the circuitry and the approximate number of circuits on the chip. SSI (small-scale integration) equals 2–10 circuits; MSI (medium-scale integration) equals 10–100 circuits; LSI (large-scale integration) equals 100–1,000 circuits; and VLSI (very-large-scale integration) equals 1,000–10,000 circuits. Finally, ULSI (ultra-large-scale integration) equals more than 10,000 circuits.

ICH (I/O controller hub)  Intel’s term for the chip used in its 8xx chipsets to interface with lower-speed devices such as PCI slots, USB ports, ATA drives, and other devices traditionally controlled by the South Bridge chip. ICH chips connect with the memory controller hub (the 8xx chipsets’ replacement for the North Bridge) through a high-speed hub interface. Current ICH chips used by Intel 8xx-series chipsets include the ICH2 and ICH4. See also MCH.

IDE (Integrated Drive Electronics)  Describes a hard disk with the disk controller circuitry integrated within it. The first IDE drives commonly were called hard cards. Also refers to the ATA interface standard—the standard for attaching hard disk drives to ISA bus IBM-compatible computers. IDE drives typically operate as though they are standard ST-506/412 drives. See also ATA.

IEEE 802.3  See 10BASE-2.

IEEE 802.11 family  A family of wireless network standards commonly known as wireless Ethernet, the most popular of which include 802.11a (54Mbps using 5GHz signaling) and 802.11b (11Mbps using 2.4GHz signaling). 802.11b is frequently called Wi-Fi. See also Wi-Fi.
IEEE 1284  A series of standards for parallel ports. IEEE 1284 includes EPP and ECP configurations as well as the older bidirectional and 4-bit compatible parallel port modes. Printer cables that can work with all modes are referred to as IEEE 1284-compliant cables. See also EPP and ECP.

IEEE 1394  See FireWire.

illegal operation  A command sent to Windows or the processor that can't be performed. Illegal operations can be triggered by software bugs or conflicts between programs in memory; although the name is reminiscent of a penalty in football, an illegal operation is hardly ever caused by the computer user. In most cases, you can continue to work and might even be able to restart the program without rebooting.

impedance  The total opposition a circuit offers to the flow of alternating current, measured in ohms.

incremental backup  A backup of all the files that have changed since the last backup.

inductive  A property in which energy can be transferred from one device to another via the magnetic field generated by the device, even though no direct electrical connection is established between the two.

.INF file  A Windows driver and device information file used to install new drivers or services.

ingot  See boule.

initiator  A device attached to the SCSI bus that sends a command to another device (the target) on the SCSI bus. The SCSI host adapter plugged into the system bus is an example of a SCSI initiator.

inkjet printer  A type of printer that sprays one or more colors of ink on the paper; it can produce output with quality approaching that of a laser printer at a lower cost.

input  Data sent to the computer from the keyboard, the telephone, a video camera, another computer, paddles, joysticks, and so on.

InstallShield  A popular program used to create installation and uninstallation routines for Windows–based programs.

instruction  Program step that tells the computer what to do for a single operation.

integrated circuit  See IC.

interface  A communications device or protocol that enables one device to communicate with another. Matches the output of one device to the input of the other device.

interlacing  A method of scanning alternate lines of pixels on a display screen. The odd lines are scanned first from top to bottom and left to right. The electron gun goes back to the top and makes a second pass, scanning the even lines. Interlacing requires two scan passes to construct a single image. Because of this additional scanning, interlaced screens often seem to flicker unless a long-persistence phosphor is used in the display. Interlaced monitors were used with the IBM 8514/A display card but are now obsolete for desktop computers.

interleave ratio  The number of sectors that pass beneath the read/write heads before the “next” numbered sector arrives. When the interleave ratio is 3:1, for example, a sector is read, two pass by, and then the next is read. A proper interleave ratio, laid down during low-level formatting, enables the disk to transfer information without excessive revolutions due to missed sectors. All modern IDE and SCSI drives have a 1:1 interleave ratio.

interleaved memory  The process of alternating access between two banks of memory to overlap accesses, thus speeding up data retrieval. Systems that require only one memory module per bank to operate can work more quickly when two are installed if the system supports interleaved memory.

internal command  In DOS, a command contained in COMMAND.COM so that no other file must be loaded to perform the command. DIR and COPY are two examples of internal commands.

internal device  A peripheral device installed inside the main system case in either an expansion slot or a drive bay.

internal drive  A disk or tape drive mounted inside one of a computer's disk drive bays (or a hard disk card, which is installed in one of the computer's slots).

Internet  A computer network that joins many government, university, and private computers together over phone lines. The Internet traces its origins to a network set up in 1969 by the Department of Defense. You can connect to the Internet through many online services, such as CompuServe and America Online, or you can connect through local Internet service providers (ISPs). Internet computers use the TCP/IP communications protocol. Several million hosts exist on the Internet; a host is a mainframe, mini, or workstation that directly supports the Internet protocol (the IP in TCP/IP).

Internet Explorer (IE)  Microsoft's line of Web browsers for Windows and Macintosh computers. Most Web sites are optimized to display best on systems running recent versions of IE.

interpreter  A program for a high-level language that translates and executes the program at the same time. The program statements that are interpreted remain in their original source language, the way the programmer wrote them—that is, the program does not need to be compiled before execution. Interpreted programs run more slowly than compiled programs and always must be run with the interpreter loaded in memory.
interrupt A suspension of a process, such as the execution of a computer program, caused by an event external to that process and performed in such a way that the process can be resumed. An interrupt can be caused by internal or external conditions, such as a signal indicating that a device or program has completed a transfer of data. Hardware interrupts (also called IRQs) are used by devices, whereas software interrupts are used by programs. See also IRQ.

interrupt vector A pointer in a table that gives the location of a set of instructions the computer should execute when a particular interrupt occurs.

IO.SYS One of the DOS/Windows 9x system files required to boot the machine. The first file loaded from disk during the boot, it contains extensions to the ROM BIOS.

IP address An identifier for a computer or device on a TCP/IP network. The format of an IP address is a 32-bit numeric address written as four numbers separated by periods, in which each number can be 0–255. The TCP/IP protocol routes messages based on the IP address of the destination.

IPv6 A new version of the IP protocol that expands the range of IP addresses from 32 bits to 128 bits, which relieves the strain on the current universe of IP addresses. IPv6 is backward compatible with IPv4 to allow its gradual adoption.

IPX (internetwork packet exchange) Novell NetWare's native LAN communications protocol (primarily in versions 4.x and earlier) used to move data between server and/or workstation programs running on different network nodes. IPX packets are encapsulated and carried by the packets used in Ethernet and the similar frames used in Token-Ring networks.

IrDA An infrared communications standard established by the Infrared Data Association in 1993. IrDA is currently used primarily for data transfer between portable computers or to allow portable computers to print to a printer with an IrDA port.

IRQ (interrupt request) Physical connections between external hardware devices and the interrupt controllers. When a device such as a floppy controller or a printer needs the attention of the CPU, an IRQ line is used to get the attention of the system to perform a task. On PC and XT IBM-compatible systems, eight IRQ lines are included, numbered IRQ0–IRQ7. On the AT and PS/2 systems, 16 IRQ lines are numbered IRQ0–IRQ15. IRQ lines must be used by only a single adapter in the ISA bus systems, but Micro Channel Architecture (MCA) adapters and most PCI-based systems can share interrupts. IRQ sharing with modern systems requires a system with PCI cards and Windows 95B or above. Windows 2000/XP are better at sharing IRQs than Windows 9x/Me.

ISA (Industry Standard Architecture) The bus architecture introduced as an 8-bit bus with the original IBM PC in 1981 and later expanded to 16 bits with the IBM PC/AT in 1984. ISA slots are occasionally found in PC systems today, but the latest chipsets have eliminated them.

ISA bus clock Clock that normally operates the ISA bus at 8.33MHz.

ISDN (Integrated Services Digital Network) An international telecommunications standard that enables a communications channel to carry digital data simultaneously with voice and video information.

ISO (International Standards Organization) The ISO, based in Paris, develops standards for international and national data communications. The U.S. representative to the ISO is the American National Standards Institute (ANSI). See also High Sierra format.

ISO 9660 An international standard that defines file systems for CD-ROM discs, independent of the operating system. ISO (International Standards Organization) 9660 has two levels. Level one provides for DOS file system compatibility, whereas level two allows filenames of up to 32 characters. See also High Sierra format.

ISP (Internet service provider) A company that provides Internet access to computer users. Most ISPs originally provided dialup analog modem service only, but many ISPs now provide various types of broadband support for DSL, cable modem, or fixed wireless Internet devices. Some ISPs, such as America Online (AOL), also provide proprietary content.

Itanium An Intel eighth-generation processor, codenamed Merced, it is the first 64-bit instruction PC processor from Intel. It features a new Explicitly Parallel Instruction Computing (EPIC) architecture for more performance when running optimized code. Also, it features internal L1/L2 and L3 error correcting code (ECC) caches to improve throughput and reliability. It was designed initially for the server or high-end workstation market. The improved Itanium 2 processor offers faster clock speeds and faster cache memory. See also L3 cache.

ITU (International Telecommunications Union) Formerly called CCITT. An international committee organized by the United Nations to set international communications recommendations—which frequently are adopted as standards—and to develop interface, modem, and data network recommendations. The Bell 212A standard for 1,200bps communication in North America, for example, is observed internationally as CCITT V.22. For 2,400bps communication, most U.S. manufacturers observe V.22bis, whereas V.32, V.32bis, V.34, and V.34+ are standards for 9,600bps, 14,400bps, 28,800bps, and 33,600bps, respectively. The V.90 standard recently was defined for 56kpbs modems.
**J-lead** J-shaped leads on chip carriers, which can be surface-mounted on a PC board or plugged into a socket that then is mounted on a PC board, usually on .050” centers.

**jabber** An error condition on an Ethernet-based network in which a defective network card or outside interference is constantly sending data, preventing the rest of the network from working.

**Java** An object-oriented programming language and environment similar to C or C++. Java was developed by Sun Microsystems and is used to create network-based applications.

**JavaScript** A scripting language developed by Netscape for Web browsers. JavaScript can perform calculations and mouse rollovers, but it doesn’t require the Web browser to download additional files, as with Java.

**Jaz drive** A proprietary type of removable media drive with a magnetic hard disk platter in a rigid plastic case. Developed by Iomega, Jaz drives were discontinued in 2002, but media is still available for both 1GB and 2GB versions of the drive.

**JEDEC (Joint Electron Devices Engineering Council)** A group that establishes standards for the electronics industry. JEDEC established the original PC66 SDRAM standard.

**Joliet** Microsoft extension of the ISO 9660 standard for recordable/rewritable CDs. Joliet is designed for use with 32-bit Windows versions that support long filenames, but it supports file/folder names up to 128 bytes (128 European or 64 Unicode characters) only. Some very long folder/filenames might need to be truncated when stored on a Joliet-format CD.

**joule** The standard unit of electrical energy, it’s frequently used to measure the effectiveness of surge suppressors.

**joystick** An input device generally used for game software, usually consisting of a central upright stick that controls horizontal and vertical motion and one or more buttons to control discrete events, such as firing guns. More complex models can resemble flight yokes and steering wheels or incorporate tactile feedback.

**JPEG (Joint Photographic Experts Group)** The international consortium of hardware, software, and publishing interests which—under the auspices of the ISO—has defined a universal standard for digital compression and decompression of still images for use in computer systems. JPEG compresses at about a 20:1 ratio before visible image degradation occurs. A lossy data compression standard that was originally designed for still images but also can compress real-time video (30 frames per second) and animation. Lossy compression permanently discards unnecessary data, resulting in some loss of precision. Files stored in the JPEG format have the extension .jpg or .jpeg.

**Jscript** Microsoft’s equivalent to JavaScript. See also JavaScript.

**jukebox** A type of CD-ROM drive that enables several CD-ROM discs to be in the drive at the same time. The drive itself determines which disc is needed by the system and loads the discs into the reading mechanism as needed.

**jumper block** A small, plastic-covered metal clip that slips over two pins protruding from a circuit board. Sometimes also called a shunt. When in place, the jumper block connects the pins electrically and closes the circuit. By doing so, it connects the two terminals of a switch, turning it “on.” Jumper blocks are commonly used to configure internal hard drives and motherboard settings.

**K6** The popular line of Socket 7 and Super Socket 7 processors developed by AMD. Members included the K6, K6-2, and K6-III.

**K56flex** A proprietary standard for 56Kbps modem transmissions developed by Rockwell and implemented in modems from a variety of vendors. Superseded by the official V.90 standard for 56Kbps modems. See also X2, V.90, and V.92.

**Kermit** A protocol designed for transferring files between microcomputers and mainframes. Developed by Frank DaCruz and Bill Catchings at Columbia University (and named after the talking frog on The Muppet Show), Kermit was widely accepted in the academic world before the advent of the Internet.

**kernel** Operating system core component.

**key disk** In software copy protection schemes popular during the 1980s, a distribution floppy disk that must be present in a floppy disk drive for an application program to run.

**keyboard** The primary input device for most computers, consisting of keys with letters of the alphabet, digits, punctuation, and function control keys.

**keyboard macro** A series of keystrokes automatically input when a single key is pressed.

**keychain drive** A popular term for small solid-state devices using flash memory that connect to a PC through the USB port. Such devices are recognized as drive letters and have typical capacities ranging from 32MB to 128MB. Most have a fixed capacity, but some have provision for upgradeable memory with SD or other small-form-factor flash memory. Also known as thumb drives.

**keylock** Physical locking mechanism to prevent internal access to the system unit or peripherals.

**kibi** A multiplier indicating 1,024 of some unit. Abbreviated as Ki. See also gibii.
**Appendix A**

**A multiplier indicating one thousand (1,000) of some unit. Abbreviated as k or K. When used to indicate a number of bytes of memory storage, the multiplier definition changes to 1,024. One kilobit, for example, equals 1,000 bits, whereas one kilobyte equals 1,024 bytes.**

**kilobyte (KB)** A unit of information storage equal to 1,000 bytes (decimal) or 1,024 bytes (binary). Binary KB are now called kibibytes. See also kibi.

**kludge** An inelegant but workable solution for a software or hardware problem.

**L1 cache (level one)** A memory cache built into the CPU core of 486 and later generation processors. See also cache and disk cache.

**L2 cache (level two)** A second-level memory cache external to the processor core, usually larger and slower than L1. Normally found on the motherboards of 386, 486, and Pentium systems and inside the processor packages or modules in Pentium Pro and later Intel processors, AMD K6-III processors, and Athlon and Duron processors. Cartridge-based caches used in the Pentium II, early Celeron, Pentium III, and Athlon processors run faster than motherboard cache but at speeds up to only one-half the CPU speed. Modern Socket 370, Socket A, and other socket-based processors contain the L2 cache inside the CPU die, enabling the L2 cache to work at the full speed of the processor. See also SEC, cache, and disk cache.

**L3 cache (level three)** A third-level memory cache external to the processor core. The only current Intel-compatible processors to include L3 cache are the Itanium and Itanium 2 processors from Intel. Depending on the model, these contain 2MB or 4MB of L3 cache that runs at full processor speed. If a motherboard provides L2 cache, such as many Super Socket 7 motherboards made for Pentium and Pentium-compatible processors, L2 cache becomes L3 cache if a processor with integrated L3 cache, such as the AMD K6-III, is used. Motherboard-based cache modules run at FSB speeds, which are much slower than on-chip or on-die processor speeds. See also cache and disk cache.

**LAN** Local area network; a network contained within a building. Both home and office networks are considered LANs. Ethernet, Fast Ethernet, Gigabit Ethernet, and Wireless Ethernet are used in office LANs, whereas home LANs might use Ethernet, Fast Ethernet, HomePNA, HomeRF, or Wi-Fi Wireless Ethernet.

**landing zone** An unused track on a disk surface on which the read/write heads can land when power is shut off. The place a parking program or a drive with an autopark mechanism parks the heads.

**LAPM (link-access procedure for modems)** An error-control protocol incorporated in CCITT Recommendation V.42. Similar to the MNP and HST protocols, it uses cyclic redundancy checking (CRC) and retransmission of corrupted data (ARQ) to ensure data reliability.

**laptop computer** A computer system smaller than a briefcase but larger than a notebook that usually has a clamshell design in which the keyboard and display are on separate halves of the system, which are hinged together. These systems normally run on battery power. Many vendors use the terms notebook and laptop computer interchangeably.

**large mode** A translation scheme used by the Award BIOS to translate the cylinder, head, and sector specifications of an IDE drive to those usable by an enhanced BIOS. It doesn’t produce the same translated values as LBA mode and is not recommended because it is not supported by other BIOS vendors.

**large-scale integration** See IC.

**laser printer** A type of printer that is a combination of an electrostatic copying machine and a computer printer. The output data from the computer is converted by an interface into a raster feed, similar to the impulses a TV picture tube receives. The impulses cause the laser beam to scan a small drum that carries a positive electrical charge. Where the laser hits, the drum is discharged. A toner, which also carries a positive charge, is then applied to the drum. This toner—a fine, black powder—sticks to only the areas of the drum that have been discharged electrically. As it rotates, the drum deposits the toner on a negatively charged sheet of paper. Another roller then heats and bonds the toner to the page. See also LED printer.

**latency**

1) The amount of time required for a disk drive to rotate half a revolution. Represents the average amount of time to locate a specific sector after the heads have arrived at a specific track. Latency is part of the average access time for a drive.

2) The initial setup time required for a memory transfer in DRAM to select the row and column addresses for the memory to be read/written.

**LBA (logical block addressing)** A method used with SCSI and IDE drives to translate the cylinder, head, and sector specifications of the drive to those usable by an enhanced BIOS. LBA is used with drives that are larger than 528MB and causes the BIOS to translate the drive’s logical parameters to those usable by the system BIOS.

**LCC (leadless chip carrier)** A type of integrated circuit package that has input and output pads rather than leads on its perimeter.

**LCD (liquid crystal display)** A display that uses liquid crystal sealed between two pieces of polarized glass. The polarity of the liquid crystal is changed by an electric current to vary the amount of light that can pass through. Because LCD displays do not generate light, they depend on either the reflection of ambient light or backlighting the screen. The best type of LCD, the active-matrix or thin-film transistor (TFT) LCD, offers fast screen updates and true color capability.
LED (light-emitting diode)  A semiconductor diode that emits light when a current is passed through it.

LED printer  A printer that uses an LED instead of a laser beam to discharge the drum.

legacy port  I/O ports used on systems before the development of the multipurpose USB port. Serial, parallel, keyboard, and PS/2 mouse ports are legacy ports.

letterbox  Refers to how wide-screen movies are displayed on TV or monitor screens with normal aspect ratios of 4:3. Because wide-screen movies have aspect ratios as high as 16:9, the wide-screen image leaves blank areas at the top and bottom of the screen. This area is sometimes used for displaying subtitles on foreign-language films. See also aspect ratio.

LIF (low insertion force)  A type of socket that requires only a minimum of force to insert a chip carrier.

light pen  A handheld input device with a light-sensitive probe or stylus connected to the computer’s graphics adapter board by a cable. Used for writing or sketching onscreen or as a pointing device for making selections. Unlike mice, it’s not widely supported by software applications.

line voltage  The AC voltage available at a standard wall outlet, nominally 110V–120V in North America and 220V–230V in Europe and Japan.

linear tape-open (LTO)  An open standard for tape backups whose first products were introduced in mid-2000. LTO was jointly developed by Seagate, IBM, and Hewlett-Packard. Ultrium format products have capacities of up to 100GB, whereas the faster Accelis products have capacities of up to 25GB.

lithium-ion  A portable system battery type that is longer-lived than either NiCad or NiMH technologies, can’t be overcharged, and holds a charge well when not in use. Lithium-ion batteries are also lighter weight than the NiCad and NiMH technologies. Because of these superior features, Li-ion batteries have come to be used in all but the very low end of the portable system market.

local area network (LAN)  The connection of two or more computers, usually via a network adapter card or NIC.

local bus  A generic term used to describe a bus directly attached to a processor that operates at the processor’s speed and data-transfer width.

local echo  A modem feature that enables the modem to send copies of keyboard commands and transmitted data to the screen. When the modem is in command mode (not online to another system), the local echo usually is invoked through an ATE1 command, which causes the modem to display the user’s typed commands. When the modem is online to another system, the local echo is invoked by an ATO command, which causes the modem to display the data it transmits to the remote system.

logical drive  A drive as named by a DOS drive specifier, such as C: or D:. Under DOS 3.3 or later, a single physical drive can act as several logical drives, each with its own specifier. A primary partition can contain only one logical drive; an extended partition can contain one or more logical drives. See also extended partition and primary partition.

logical unit number  See LUN.

lossless compression  A compression technique that preserves all the original information in an image or other data structures. PKZIP and Microsoft CAB files are popular applications of lossless compression.

lossless linking  A technique used by DVD+RW drives to enable the DVD+RW video writing process to pause and continue as data is available. Lossless linking enables DVD+RW video media to be read by standalone DVD video players and DVD-ROM drives.

lossy compression  A compression technique that achieves optimal data reduction by discarding redundant and unnecessary information in an image. MP3, MPEG, and JPEG are popular examples of lossy compression.

lost clusters  Clusters that have been marked accidentally as “unavailable” in the FAT even though they don’t belong to any file listed in a directory. See also cluster.

low-level formatting  Formatting that divides tracks into sectors on the platter surfaces. Places sector-identifying information before and after each sector and fills each sector with null data (usually hex F6). Specifies the sector interleave and marks defective tracks by placing invalid checksum figures in each sector on a defective track.

LPT port  Line printer port, a common system abbreviation for a parallel printer port. Common LPT port numbers range from LPT1 to LPT3.

LPX  A semiproprietary motherboard design used in many Low Profile or Slimline case systems. Because no formal standard exists, these typically are not interchangeable between vendors and are often difficult to find replacement parts for or upgrade.

luminance  Measure of brightness usually used in specifying monitor brightness.

LUN (logical unit number)  A number given to a device (a logical unit) attached to a SCSI physical unit and not directly to the SCSI bus. Although as many as eight logical units can be attached to a single physical unit, a single logical unit typically is a built-in part of a single physical unit. A SCSI hard disk, for example, has a built-in SCSI bus adapter that is assigned a physical unit number or SCSI ID, and the controller and drive portions of the hard disk are assigned a LUN (usually 0). See also PUN.
1402  Appendix A  Glossary

LZW (Lempel Zev Welch)  A lossless compression scheme used in the GIF and TIFF graphic formats, named after its co-creators, Abraham Lempel, Jacob Ziv, and Terry Welch.

MAC address  Short for Media Access Control address, this is a unique hardware number assigned to network hardware, such as NICs and routers. The MAC address assigned to the WAN side of some broadband Internet routers can be changed to equal the MAC address of the NIC previously used to attach to a broadband device, such as a cable modem.

machine address  A hexadecimal (hex) location in memory.

machine language  Hexadecimal program code a computer can understand and execute. It can be output from the assembler or compiler.

macro  A series of commands in an application that can be stored and played back on demand. Many applications from various vendors support Microsoft Visual Basic for Applications as their macro language.

macro virus  A computer virus that uses a scripting language to infect Microsoft Word document templates or email systems.

magnetic domain  A tiny segment of a track just large enough to hold one of the magnetic flux reversals that encode data on a disk surface.

magneto-optical recording  An erasable optical disk recording technique that uses a laser beam to heat pits on the disk surface to the point at which a magnet can make flux changes.

magneto-resistive  A technology originally developed by IBM and commonly used for the read element of a read/write head on a high-density magnetic disk. Based on the principle that the resistance to electricity changes in a material when brought into contact with a magnetic field, in this case, the read element material and the magnetic bit. Such drives use a magneto-resistive read sensor for reading and a standard inductive element for writing. A magneto-resistive read head is more sensitive to magnetic fields than inductive read heads. Giant magneto-resistive heads are an improved version that store more data in the same space.

mainframe  A somewhat vague distinction that identifies any large computer system normally capable of supporting many users and programs simultaneously.

mask  A photographic map of the circuits for a particular layer of a semiconductor chip in manufacturing the chip.

master boot record (MBR)  On hard disks, a one-sector-long record that contains the master boot program as well as the master partition table containing up to four partition entries. The master boot program reads the master partition table to determine which of the four entries is active (bootable) and then loads the first sector of that partition, called the volume boot record. The master boot program tests the volume boot record for a 55AAh signature at offset 510; if it’s present, program execution is transferred to the volume boot sector, which typically contains a program designed to load the operating system files. The MBR is always the first physical sector of the disk, at Cylinder 0, Head 0, Sector 1. Also called master boot sector.

math coprocessor  A processing chip designed to quickly handle complex arithmetic computations involving floating-point arithmetic, offloading these from the main processor. Originally contained in a separate coprocessor chip, starting with the 486 family of processors. Intel now has incorporated the math coprocessor into the main processors in what is called the floating-point unit.

MCA (Micro Channel Architecture)  Developed by IBM for the PS/2 line of computers and introduced on April 2, 1987. Features include a 16- or 32-bit bus width and multiple master control. By allowing several processors to arbitrate for resources on a single bus, the MCA is optimized for multitasking, multiprocessor systems. Offers switchless configuration of adapters, which eliminates one of the biggest headaches of installing older adapters. MCA systems became obsolete after the development of the PCI bus.

MCGA (multicolor graphics array)  A type of PC video display circuit introduced by IBM on April 2, 1987, which supports text and graphics. Text is supported at a maximum resolution of 80×25 characters in 16 colors with a character box of 8×16 pixels.

Graphics are supported at a maximum resolution of 320×200 pixels in 256 (from a palette of 262,144) colors or 640×480 pixels in two colors. The MCGA outputs an analog signal with a horizontal scanning frequency of 31.5 KHz and supports analog color or analog monochrome displays.

MCH (memory controller hub)  Intel’s term for the chip used in its 8xx-series chipsets to connect the processor with high-bandwidth devices such as memory, video, and the system bus, replacing the North Bridge chip. MCH chips connect with the I/O controller hub (the 8xx chipsets’ replacement for the South Bridge) through a high-speed hub interface. See also ICH.

MCI (media control interface)  A device-independent specification for controlling multimedia devices and files. MCI is a part of the multimedia extensions and offers a standard interface set of device control commands. MCI commands are used for audio recording and playback and animation playback. Device types include CD audio, digital audio tape players, scanners, MIDI sequencers, videotape players or recorders, and audio devices that play digitized waveform files.
MDA (monochrome display adapter; also, MGA—mono graphics adapter)  A type of PC video display adapter introduced by IBM on August 12, 1981, that supports text only. Text is supported at a maximum resolution of 80×25 characters in four colors with a character box of 9×14 pixels. Colors, in this case, indicate black, white, bright white, and underlined. Graphics modes are not supported. The MDA outputs a digital signal with a horizontal scanning frequency of 18.432KHz and supports TTL monochrome displays. The IBM MDA card also includes a parallel printer port.

mean time between failure  See MTBF.

mean time to repair  See MTTR.

mebi  A multiplier indicating 1,048,576 of a unit of measurement.

mebibyte (Mi)  A unit of information storage equal to 1,048,576 bytes (1,024×1,024 equals 1Mi). This value was previously called a binary megabyte. See also megabyte and kilobyte.

medium  The magnetic coating or plating that covers a disk or tape.

mega  A multiplier indicating one million (1,000,000) of some unit. Abbreviated as m or M. Traditionally, mega has also been defined as 1,048,576 (1,024 kilobytes, where kilobyte equals 1,024) in applications such as memory sizing or disk storage (as defined by many BIOSs and by FDISK and other disk preparation programs). The term mebi is now used for 1,048,576. See also mebi.

megabyte (MB)  A unit of information storage equal to 1,000,000 bytes. Also called a decimal megabyte. The value 1,048,576 bytes has been called a binary megabyte but is now known as a mebibyte. See also mebibyte.

megapixel  A unit of digital camera resolution equal to approximately 1,000,000 pixels. A one-megapixel camera has a resolution of approximately 1,522×864; a two-megapixel camera has a resolution of approximately 1,760×1,168. Finally, a three-megapixel camera has a resolution of approximately 2,160×1,440. One-megapixel or lower-resolution cameras are suitable for 4″×6″ or smaller snapshots only, whereas two-megapixel cameras produce excellent 5″×7″ enlargements and acceptable 8″×10″ enlargements. Three-megapixel or higher-resolution cameras produce excellent 8″×10″ and 11″×14″ enlargements. The higher the megapixel rating, the more flash memory space is used by each picture and the longer it takes each picture to be recorded to flash memory.

memory  Any component in a computer system that stores information for future use.

memory caching  A service provided by extremely fast memory chips that keeps copies of the most recent memory accesses. When the CPU makes a subsequent access, the value is supplied by the fast memory rather than by the relatively slow system memory. L1 and L2 caches are memory caches found on most recent processors. See also L1 cache, L2 cache, and L3 cache.

Memory Stick  A Sony-developed flash memory device that’s about the size of a stick of gum. It is used by digital cameras, camcorders, digital music players, and voice recorders—primarily those made by Sony.

memory-resident program  A program that remains in memory after it has been loaded, consuming memory that otherwise might be used by application software.

menu software  Utility software that makes a computer running DOS easier to use by replacing DOS commands with a series of menu selections.

MFM encoding (modified frequency modulation encoding)  A method of encoding data on the surface of a disk. The coding of a bit of data varies by the coding of the preceding bit to preserve clocking information. Used only by floppy drives today because it stores less data than other types of encoding such as RLL. See also RLL.

MHz  An abbreviation for megahertz, a unit of measurement indicating the frequency of one million cycles per second. One hertz (Hz) is equal to one cycle per second. Named after Heinrich R. Hertz, a German physicist who first detected electromagnetic waves in 1883.

MI/MIC (mode indicate/mode indicate common)  Also called forced or manual originate. Provided for installations in which equipment other than the modem does the dialing. In such installations, the modem operates in dumb mode (no autodial capability), yet must go off-hook in originate mode to connect with answering modems.

micro (µ)  A prefix indicating one millionth (1/1,000,000 or .000001) of some unit.

micron  A unit of measurement equaling one millionth of a meter. Often used in measuring the size of circuits in chip manufacturing processes. Current state-of-the-art chip fabrication builds chips with 0.13 to 0.15-micron circuits.

microprocessor  A solid-state central processing unit much like a computer on a chip. An integrated circuit that accepts coded instructions for execution.

microsecond (µs)  A unit of time equal to one millionth (1/1,000,000 or .000001) of a second.
MIDI (musical instrument digital interface)
An interface and file format standard for connecting a musical instrument to a microcomputer and storing musical instrument data. Multiple musical instruments can be daisy-chained and played simultaneously with the help of the computer and related software. The various operations of the instruments can be captured, saved, edited, and played back. A MIDI file contains note information, timing (how long a note is held), volume, and instrument type for as many as 16 channels. Sequencer programs are used to control MIDI functions such as recording, playback, and editing. MIDI files store only note instructions and not actual sound data. MIDI files can be played back by virtually all sound cards, but old sound cards might use FM synthesis to imitate the musical instruments called for in the MIDI file. Recent sound cards use stored musical instrument samples for more realistic MIDI playback.

MII A Socket 7–compatible processor originally developed by Cyrix and now sold by VIA Technologies as the VIA Cyrix MII.

milli (m) A prefix indicating one thousandth (1/1,000 or .001) of some unit.

millisecond (ms) A unit of time equal to one thousandth (1/1,000 or .001) of a second.

MIME (Multipurpose Internet Mail Extensions)
Allows Internet and email services to exchange binary files and select the proper program to open the file after it's received.

minitower A type of PC system case that is shorter than a full- or mid-sized tower. Most low-cost computers sold at retail stores use the minitower case combined with a Micro-ATX motherboard.

MIPS (million instructions per second) Refers to the average number of machine-language instructions a computer can perform or execute in one second. Because various processors can perform different functions in a single instruction, MIPS should be used only as a general measure of performance among various types of computers.

MMX An Intel processor enhancement that adds 57 new instructions designed to improve multimedia performance. MMX also implies a doubling of the internal L1 processor cache on Pentium MMX processors compared to non-MMX Pentium processors. Later processors also include MMX along with other multimedia instructions.

mnemonic An abbreviated name for something used in a manner similar to an acronym. Computer processor instructions are often abbreviated with a mnemonic, such as JMP (jump), CLR (clear), STO (store), and INIT (initialize). A mnemonic name for an instruction or an operation makes it easy to remember and convenient to use.

MNP (Microcom Networking Protocol)
Asynchronous error-control and data-compression protocols developed by Microcom, Inc., and now in the public domain. They ensure error-free transmission through error detection (CRC) and retransmission of errored frames. MNP Levels 1–4 cover error control and have been incorporated into CCITT Recommendation V.42. MNP Level 5 includes data compression but is eclipsed in superiority by V.42bis—an international standard that is more efficient. Most high-speed modems connect with MNP Level 5 if V.42bis is unavailable. MNP Level 10 provides error correction for impaired lines and adjusts to the fastest possible speed during connection. MNP Level 10EC is an improved version of MNP Level 10, adding more reliability and support for cellular phone hand-offs.

MO (magneto-optical) MO drives use both magnetic and optical storage properties. MO technology is erasable and recordable, as opposed to CD-ROM (read-only) and WORM (write-once) drives. MO uses laser and magnetic field technology to record and erase data.

mobile module (MMO) A type of processor packing from Intel for mobile computers consisting of a Pentium or newer processor mounted on a small daughterboard along with the processor voltage regulator, system’s L2 cache memory, and North Bridge part of the motherboard chipset.

modem (modulator/demodulator) A device that converts electrical signals from a computer into an audio form transmittable over telephone lines, or vice versa. It modulates, or transforms, digital signals from a computer into the analog form that can be carried successfully on a phone line; it also demodulates signals received from the phone line back to digital signals before passing them to the receiving computer. To avoid confusion with other types of Internet connection devices such as cable modems, modems are often called analog modems or dialup modems.

modulation The process of modifying some characteristic of a carrier wave or signal so that it varies in step with the changes of another signal, thus carrying the information of the other signal.

module An assembly that contains a complete circuit or subcircuit.

monitor See display.

monochrome display adapter See MDA.

MOS (metal-oxide semiconductor) Refers to the three layers used in forming the gate structure of a field-effect transistor (FET). MOS circuits offer low-power dissipation and enable transistors to be jammed closely together before a critical heat problem arises. PMOS, the oldest type of MOS circuit, is a silicon-gate P-channel MOS process that uses currents made up of positive charges. NMOS is a silicon-gate N-channel
MOS process that uses currents made up of negative charges and is at least twice as fast as PMOS. CMOS, complementary MOS, is nearly immune to noise, runs off almost any power supply, and is an extremely low-power circuit technique.

**motherboard** The main circuit board in the computer. Also called planar, system board, or backplane.

**mouse** An input device invented by Douglas Engelbart of Stanford Research Center in 1963 and popularized by Xerox in the 1970s. A mechanical mouse consists of a roller ball and a tracking mechanism on the underside that relays the mouse's horizontal and vertical position to the computer, allowing precise control of the pointer location onscreen. The top side features two or three buttons and possibly a small wheel used to select or click items onscreen. Old-style optical mice sold in the 1980s used a single optical sensor and a grid-marked pad as an alternative to the roller ball. The latest optical mice use two optical sensors and can be moved across virtually any nonmirrored surface.

**MPC** A trademarked abbreviation for Multimedia Personal Computer. The original MPC specification was developed by Tandy Corporation and Microsoft as the minimum platform capable of running multimedia software. In the summer of 1995, MPC Marketing Council introduced an upgraded MPC 3 standard. The MPC 1 Specification defines the following minimum standard requirements: a 386SX or 486 CPU; 2MB RAM; 30MB hard disk; VGA video display; 8-bit digital audio subsystem; CD-ROM drive; and systems software compatible with the applications programming interfaces (APIs) of Microsoft Windows version 3.1 or later. The MPC 2 Specification defines the following minimum standard requirements: 25MHz 486SX with 4MB RAM; 160MB hard disk; 16-bit sound card; 65,536-color video display; double-speed CD-ROM drive; and systems software compatible with the APIs of Microsoft Windows version 3.1 or later. The MPC 3 Specification defines the following minimum standard requirements: 75MHz Pentium with 8MB RAM; 540MB hard disk; 16-bit sound card; 65,36-color video display; quad-speed CD-ROM drive; OM-1-compliant MPEG-1 video, and systems software compatible with the APIs of Microsoft Windows version 3.1 and DOS 6.0 or later. Virtually all computers sold since 1995 exceed MPC 3 standards.

**MPEG (Motion Picture Experts Group)** A working ISO committee that has defined standards for lossy digital compression and decompression of motion video/audio for use in computer systems. The MPEG-1 standard delivers decompression data at 1.2Mbits–1.5Mbits, enabling CD players to play full-motion color movies at 30 frames per second. MPEG-1 compresses at about a 50:1 ratio before image degradation occurs, but compression ratios as high as 200:1 are attainable. MPEG-2 extends to the higher data rates (2Mbits–15Mbits) necessary for signals delivered from remote sources (such as broadcast, cable, or satellite). MPEG-2 is designed to support a range of picture aspect ratios, including 4:3 and 16:9. MPEG compression produces about a 50% volume reduction in file size. MP3 (the audio layer portion of the MPEG-1 standard) provides a wide range of compression ratios and file sizes for digital music storage, making it the de facto standard for exchanging digital music through sites such as Napster and its many rivals. See also *lossy compression*.

**MPR** The Swedish government standard for maximum video terminal radiation. The current version is called MPR II, but most monitors also comply with the newer and more restrictive TCO standards. See also *TCO*.

**MSDOS.SYS** One of the DOS/Windows 9x system files required to boot the machine. Contains the primary DOS routines. Loaded by IO.SYS, it in turn loads COMMAND.COM.

**Mt. Rainier** An emerging standard for CD-RW and DVD+RW drives that provides for native operating system support of CD-RW and rewriteable DVD media. Drives and operating systems that support the Mt. Rainier standard (www.mt-rainier.org) can read or write Mt. Rainier-formatted CD-R/RW or DVD+R/RW media without the need for proprietary packet-reading software such as Roxio's UDF Volume Reader for DirectCD-formatted media (www.roxio.com).

**MTBF (mean time between failure)** A statistically derived measure of the probable time a device will continue to operate before a hardware failure occurs, usually given in hours. Because no standard technique exists for measuring MTBF, a device from one manufacturer can be significantly more or significantly less reliable than a device with the same MTBF rating from another manufacturer.

**MTTR (mean time to repair)** A measure of the probable time it will take a technician to service or repair a specific device, usually given in hours.

**Multichannel Multipoint Distribution Service (MMDS)** The most common form of so-called “wireless cable TV,” MMDS is also used for two-way wireless Internet service. One of the leading MMDS technology manufacturers is Navini Networks (www.navini.com).

**multicolor graphics array** See MCGA.

**multimedia** The integration of sound, graphic images, animation, motion video, and text in one environment on a computer. It is a set of hardware and software technologies that is rapidly changing and enhancing the computing environment.

**multisession** A term used in CD-ROM recording to describe a recording event. Multisession capabilities allow data recording on the disk at various times in several recording sessions. Kodak's Photo CD is an example of multisession CD-R technology. See also *session* (single or multisession).
multitask  To run several programs simultaneously.
multithread  To concurrently process more than one message by an application program. OS/2 and 32-bit versions of Windows are examples of multi-threaded operating systems. Each program can start two or more threads, which carry out various interrelated tasks with less overhead than two separate programs would require.
multiuser system  A system in which several computer terminals share the same central processing unit (CPU).
nano (n)  A prefix indicating one billionth 

\((1/1,000,000,000 \text{ or } .000000001)\) of some unit.
nanosecond (ns)  A unit of time equal to one billionth 

\((1/1,000,000,000 \text{ or } .000000001)\) of a second.
NetBEUI (NetBIOS Extended User Interface)  A network protocol used primarily by Windows NT and Windows 9x and most suitable for small peer-to-peer networks. NetBEUI is not supported by Microsoft in Windows XP and above but can still be manually installed for use in troubleshooting computers.
NetBIOS (Network Basic Input/Output System)  A commonly used network protocol originally developed by IBM and Sytek for PC local area networks. NetBIOS provides session and transport services (Layers 4 and 5 of the OSI model).
NetWare   Novell’s server-based network for large businesses. NetWare 5 and NetWare 6 are designed to work well with IP-based networks.
network  A system in which several independent computers are linked to share data and peripherals, such as hard disks and printers.
network interface card (NIC)  An adapter that connects a PC to a network.
Network Layer  In the OSI reference model, the layer that switches and routes the packets as necessary to get them to their destinations. This layer is responsible for addressing and delivering message packets. See also OSI.
NiCad  The oldest of the three battery technologies used in portable systems, nickel cadmium batteries are rarely used in portable systems today because of their shorter life and sensitivity to improper charging and discharging. See also NiMH and lithium-ion.
NiMH  A battery technology used in portable systems. Nickel metal-hydride batteries have approximately a 30% longer life than NiCads, are less sensitive to the memory effect caused by improper charging and discharging, and do not use the environmentally dangerous substances found in NiCads. Newer lithium-ion (Li-ion) batteries are far superior. NiMH batteries can sometimes be used in place of NiCads.
NLX  A new low-profile motherboard form factor standard that is basically an improved version of the semi-proprietary LPX design. It’s designed to accommodate larger processor and memory form factors and incorporate newer bus technologies, such as AGP and USB. Besides design improvements, it is fully standardized, which means you should be able to replace one NLX board with another from a different manufacturer—something that was not normally possible with LPX.
node  A device on a network. Also any junction point at which two or more items meet.
noise  Any unwanted disturbance in an electrical or mechanical system.
noninterlaced monitor  A desirable monitor design in which the electron beam sweeps the screen in lines from top to bottom, one line after the other, completing the entire screen in one pass. Virtually all CRTs sold recently for desktop use are noninterlaced.
nonvolatile memory (NVRAM)  Random-access memory whose data is retained when power is turned off. ROM/EPROM/EEPROM (flash) memory are examples of nonvolatile memory. Sometimes NVRAM is retained without any power whatsoever, as in EEPROM or flash memory devices. In other cases, the memory is maintained by a small battery. NVRAM that is battery maintained is sometimes also called CMOS memory (although CMOS RAM technically is volatile). CMOS NVRAM is used in IBM-compatible systems to store configuration information. True NVRAM often is used in intelligent modems to store a user-defined default configuration loaded into normal modem RAM at power-up.
nonvolatile RAM disk  A RAM disk powered by a battery supply so that it continues to hold its data during a power outage.
North Bridge  The Intel term for the main portion of the motherboard chipset that incorporates the interface between the processor and the rest of the motherboard. The North Bridge contains the cache, main memory, and AGP controllers, as well as the interface between the high-speed (normally 66MHz or 100MHz) processor bus and the 33MHz PCI (peripheral component interconnect) or 66MHz AGP (accelerated graphics port) buses. The functional equivalent of the North Bridge on the latest 8xx-series chipsets from Intel is the MCH. See also chipset, ICH, MCH, and South Bridge.
notebook computer  A very small personal computer approximately the size of a notebook.
NTSC  The National Television Standards Committee, which governs the standard for television and video playback and recording in the United States. The NTSC was originally organized in 1941 when TV broadcasting first began on a wide scale in black and white, and the format was revised in 1953.
null modem A serial cable wired so that two data terminal equipment (DTE) devices, such as personal computers, or two data communication equipment (DCE) devices, such as modems or mice, can be connected. Also sometimes called a modem-eliminator or a LapLink cable. To make a null-modem cable with DB-25 connectors, you wire these pins together: 1-1, 2-3, 3-2, 4-5, 5-4, 6-8-20, 20-8-6, and 7-7.

numeric coprocessor See math coprocessor.

NVRAM (nonvolatile random access memory) Memory that retains data without power. Flash memory and battery-backed CMOS RAM are examples of NVRAM.

object hierarchy Occurs in a graphical program when two or more objects are linked and one object's movement is dependent on the other object. This is known as a parent-child hierarchy. In an example using a human figure, the fingers would be child objects to the hand, which is a child object to the arm, which is a child to the shoulder, and so on. Object hierarchy provides much control for an animator in moving complex figures.

OC (optical carrier) rates Various data rates for optical fiber used in Internet backbones, based on the OC-1 rate of 51.84Mbps. Multiply the OC rate by 51.84Mbps to derive the data rate. For example, OC-12 is 622.08Mbps (51.84×12).

Occam’s Razor Also spelled Ockham’s Razor; popular name for the principle that the simplest explanation is usually the correct one—a very useful principle in computer troubleshooting.

OCR (optical character recognition) An information-processing technology that converts human-readable text into computer data. Usually a scanner is used to read the text on a page, and OCR software converts the images to characters. Advanced OCR programs, such as OmniPage, can also match fonts, re-create page layouts, and scan graphics into machine-readable form.

ODI (Open Data-link Interface) A device driver standard from Novell that enables multiple protocols to run on the same network adapter card. ODI adds functionality to Novell’s NetWare and network computing environments by supporting multiple protocols and drivers.

OEM (original equipment manufacturer) Any manufacturer who sells its product to a reseller. Usually refers to the original manufacturer of a particular device or component. Most HP hard disks, for example, are made by Seagate Technologies, who is considered the OEM. OEM products often differ in features from retail products and can have very short warranty periods if purchased separately from their intended use.

OLE (object linking and embedding) An enhancement to the original Dynamic Data Exchange (DDE) protocol that enables the user to embed or link data created in one application to a document created in another application and subsequently edit that data directly from the final document.

online fallback A feature that enables high-speed error-control modems to monitor line quality and fall back to the next lower speed if line quality degrades. Some modems fall forward as line quality improves.

open architecture A system design in which the specifications are made public to encourage third-party vendors to develop add-on products. The PC is a true open architecture system, but the Macintosh is proprietary.

operating system (OS) A collection of programs for operating the computer. Operating systems perform housekeeping tasks, such as input and output between the computer and peripherals and accepting and interpreting information from the keyboard. Windows XP and MacOS X are examples of popular OSs.

optical disk A disk that encodes data as a series of reflective pits that are read (and sometimes written) by a laser beam.

Orange Book The standards for recordable (CD-R) and rewritable (CD-RW) compact discs.

originate mode A state in which the modem transmits at the predefined low frequency of the communications channel and receives at the high frequency. The transmit/receive frequencies are the reverse of the called modem, which is in answer mode. See also answer mode.

OS/2 An operating system originally developed through a joint effort by IBM and Microsoft Corporation and later by IBM alone. Originally released in 1987, OS/2 is a 32-bit operating system designed to run on computers using the Intel 386 or later microprocessors. The OS/2 Workplace Shell, an integral part of the system, is a graphical interface similar to Microsoft Windows and the Apple Macintosh system. OS/2 Warp 4 is the most recent one and is used primarily as a server or in back-office functions today.

for color. The NTSC format has 525 scan lines, a field frequency of 60Hz, a broadcast bandwidth of 4MHz, a line frequency of 15.75kHz, a frame frequency of 1/30 of a second, and a color subcarrier frequency of 3.58MHz. It is an interlaced signal, which means it scans every other line each time the screen is refreshed. The signal is generated as a composite of red, green, and blue signals for color and includes an FM frequency for audio and a signal for stereo. See also PAL and SECAM, which are incompatible systems used in Europe. NTSC is also called composite video.

null modem A serial cable wired so that two data terminal equipment (DTE) devices, such as personal computers, or two data communication equipment (DCE) devices, such as modems or mice, can be connected. Also sometimes called a modem-eliminator or a LapLink cable. To make a null-modem cable with DB-25 connectors, you wire these pins together: 1-1, 2-3, 3-2, 4-5, 5-4, 6-8-20, 20-8-6, and 7-7.

numeric coprocessor See math coprocessor.

NVRAM (nonvolatile random access memory) Memory that retains data without power. Flash memory and battery-backed CMOS RAM are examples of NVRAM.

object hierarchy Occurs in a graphical program when two or more objects are linked and one object's movement is dependent on the other object. This is known as a parent-child hierarchy. In an example using a human figure, the fingers would be child objects to the hand, which is a child object to the arm, which is a child to the shoulder, and so on. Object hierarchy provides much control for an animator in moving complex figures.

OC (optical carrier) rates Various data rates for optical fiber used in Internet backbones, based on the OC-1 rate of 51.84Mbps. Multiply the OC rate by 51.84Mbps to derive the data rate. For example, OC-12 is 622.08Mbps (51.84×12).

Occam’s Razor Also spelled Ockham’s Razor; popular name for the principle that the simplest explanation is usually the correct one—a very useful principle in computer troubleshooting.

OCR (optical character recognition) An information-processing technology that converts human-readable text into computer data. Usually a scanner is used to read the text on a page, and OCR software converts the images to characters. Advanced OCR programs, such as OmniPage, can also match fonts, re-create page layouts, and scan graphics into machine-readable form.

ODI (Open Data-link Interface) A device driver standard from Novell that enables multiple protocols to run on the same network adapter card. ODI adds functionality to Novell’s NetWare and network computing environments by supporting multiple protocols and drivers.

OEM (original equipment manufacturer) Any manufacturer who sells its product to a reseller. Usually refers to the original manufacturer of a particular device or component. Most HP hard disks, for example, are made by Seagate Technologies, who is considered the OEM. OEM products often differ in features from retail products and can have very short warranty periods if purchased separately from their intended use.

OLE (object linking and embedding) An enhancement to the original Dynamic Data Exchange (DDE) protocol that enables the user to embed or link data created in one application to a document created in another application and subsequently edit that data directly from the final document.

online fallback A feature that enables high-speed error-control modems to monitor line quality and fall back to the next lower speed if line quality degrades. Some modems fall forward as line quality improves.

open architecture A system design in which the specifications are made public to encourage third-party vendors to develop add-on products. The PC is a true open architecture system, but the Macintosh is proprietary.

operating system (OS) A collection of programs for operating the computer. Operating systems perform housekeeping tasks, such as input and output between the computer and peripherals and accepting and interpreting information from the keyboard. Windows XP and MacOS X are examples of popular OSs.

optical disk A disk that encodes data as a series of reflective pits that are read (and sometimes written) by a laser beam.

Orange Book The standards for recordable (CD-R) and rewritable (CD-RW) compact discs.

originate mode A state in which the modem transmits at the predefined low frequency of the communications channel and receives at the high frequency. The transmit/receive frequencies are the reverse of the called modem, which is in answer mode. See also answer mode.

OS/2 An operating system originally developed through a joint effort by IBM and Microsoft Corporation and later by IBM alone. Originally released in 1987, OS/2 is a 32-bit operating system designed to run on computers using the Intel 386 or later microprocessors. The OS/2 Workplace Shell, an integral part of the system, is a graphical interface similar to Microsoft Windows and the Apple Macintosh system. OS/2 Warp 4 is the most recent one and is used primarily as a server or in back-office functions today.
Appendix A

OSI (Open Systems Interconnection)  A reference model developed by the International Organization for Standardization (ISO) in the 1980s, the OSI model splits a computer’s networking stack into seven discrete layers. Each layer provides specific services to the layers above and below it. From the top down, the Application Layer is responsible for program-to-program communication; the Presentation Layer manages data representation conversions. Next, the Session Layer is responsible for establishing and maintaining communications channels, and the Transport Layer is responsible for the integrity of data transmission. The Network Layer routes data from one node to another, the Data Link Layer is responsible for physically passing data from one node to another, and finally, the Physical Layer is responsible for moving data on and off the network media.

output  Information processed by the computer or the act of sending that information to a mass storage device, such as a video display, printer, or modem.

overclocking  The process of running a processor or video card at a speed faster than the officially marked speed by using a higher clock multiplier, faster bus speed, or faster core clock speed. Not recommended or endorsed by processor or video card manufacturers. See also clock multiplier.

OverDrive  An Intel trademark name for its line of upgrade processors for 486, Pentium, and Pentium Pro systems. Although Intel no longer sells OverDrive processors, similar products are available from Evergreen Technologies and PowerLeap Products, Inc., for these processors plus Pentium II, Pentium III, Pentium 4, and Celeron-based systems.

overlay  Part of a program loaded into memory only when it is required.

overrun  A situation in which data moves from one device more quickly than a second device can accept it.

overscanning  A technique used in consumer display products that extends the deflection of a CRT’s electron beam beyond the physical boundaries of the screen to ensure that images always fill the display area.

overwrite  To write data on top of existing data, thus erasing the existing data.

package  A device that includes a chip mounted on a carrier and sealed.

packet  A message sent over a network that contains data and a destination address.

packet writing  A recording technique that sends data to a CD-R or CD-RW disc in multiple blocks, enabling normal writing processes in Windows Explorer to be used instead of a CD-mastering program. Compatible packet-reading software, such as Roxio’s UDF Reader for DirectCD, must be used on systems that don’t have a CD-R or CD-RW drive to enable the media to be read. See also Mt. Rainier.

pairing  Combining processor instructions for optimal execution on superscalar processors.

PAL  1) Phase Alternating Line system. Invented in 1961, a system of TV broadcasting used in England and other European countries (except France). PAL’s image format is 4:3, 625 lines, 50Hz, and 4MHz video bandwidth with a total 8MHz of video channel width. With its 625-line picture delivered at 25 frames per second, PAL provides a better image and an improved color transmission over the NTSC system used in North America. As a consequence, PAL and NTSC video tapes aren’t interchangeable. 2) Programmable array logic, a type of chip that has logic gates specified by a device programmer.

palmtop computer  A computer system smaller than a notebook that is designed so it can be held in one hand while being operated by the other. Many are now called PDAs or personal digital assistants.

parallel  A method of transferring data characters in which the bits travel down parallel electrical paths simultaneously—for example, eight paths for 8-bit characters. Data is stored in computers in parallel form but can be converted to serial form for certain operations.

parity  A method of error checking in which an extra bit is sent to the receiving device to indicate whether an even or odd number of binary 1 bits was transmitted. The receiving unit compares the received information with this bit and can obtain a reasonable judgment about the validity of the character. The same type of parity (even or odd) must be used by two communicating computers, or both may omit parity. When parity is used, a parity bit is added to each transmitted character. The bit’s value is 0 or 1, to make the total number of 1s in the character even or odd, depending on which type of parity is used. Parity checking isn’t widely supported on recent systems, but memory with parity bits can be used as ECC memory on systems with ECC-compatible chipsets. See also ECC.

park program  A program that executes a seek to the highest cylinder or just past the highest cylinder of a drive so the potential of data loss is minimized if the drive is moved. Park programs are not interchangeable between drives and are no longer required on most drives 40MB and above because these drives self-park their heads for safety.

partition  A section of a hard disk devoted to a particular operating system. Most hard disks have only one partition, devoted to DOS. A hard disk can have as many as four partitions, each occupied by a different operating system. DOS v3.3 or later can occupy two of these four partitions. A boot manager enables you to select the partition occupied by the operating system you want to start if you have multiple operating systems installed in different partitions. See also boot manager.
Pascal  A high-level programming language named for the French mathematician Blaise Pascal (1623–1662). Developed in the early 1970s by Niklaus Wirth for teaching programming and designed to support the concepts of structured programming.

passive matrix  Another name for dual-scan, display-type LCDs.

PC Card (PCMCIA—Personal Computer Memory Card International Association)  A credit card–sized expansion adapter for notebook and laptop PCs. PC Card is the official PCMCIA trademark; however, both PC Card and PCMCIA card are used to refer to these standards. PCMCIA cards are removable modules that can hold numerous types of devices, including memory, modems, fax/modems, radio transceivers, network adapters, solid state disks, hard disks, and flash memory adapters.

PCI (Peripheral Component Interconnect)  A standard bus specification initially developed by Intel in 1992 that bypasses the standard ISA I/O bus and uses the system bus to increase the bus clock speed and take full advantage of the CPU's data path. The most common form of PCI is 32 bits wide running at 33MHz, but 66MHz and 64-bit wide versions of PCI are frequently used on servers.

PCI Express  A high-speed serial I/O interconnect standard being developed by the PCI-SIG (www.pcisig.com) as an eventual replacement for the original PCI standard. The initial version of PCI Express supports 0.8V signaling at 2.5GHz.

PCL (Printer Control Language)  Developed by Hewlett-Packard in 1984 as a language for the HP LaserJet printer. PCL is now the de facto industry standard for PC printing. PCL defines a standard set of commands, enabling applications to communicate with HP or HP-compatible printers and is supported by virtually all printer manufacturers. Various levels of PCL are supported by HP and other brands of laser and inkjet printers.

PCM (pulse code modulation)  A technique for digitizing analog signals by sampling the signal and converting each sample into a binary number. Also stands for powertrain control module, which is what the computer in most modern automobiles is called.

PDA (personal digital assistant)  A handheld, palm-sized computer that functions primarily as a personal organizer and can be combined with a cellular phone or pager. Leading examples include the Palm series, Windows–based PalmPCs, and the Handspring (which also runs the Palm OS).

PDF (portable document format)  Files with this extension can be read with the Adobe Acrobat Reader. See also Acrobat.

peer-to-peer  A type of network in which any computer can act as both a server (by providing access to its resources to other computers) and a client (by accessing shared resources from other computers).

pel  See pixel.

Pentium  An Intel microprocessor with 32-bit registers, a 64-bit data bus, and a 32-bit address bus. The Pentium has a built-in L1 cache segmented into a separate 8KB cache for code and another 8KB cache for data. The Pentium includes an FPU or math coprocessor. It is backward compatible with the 486 and can operate in real, protected virtual, and virtual real modes. The MMX Pentium has a 16KB cache for code, has a 16KB cache for data, and adds the MMX instruction set.

Pentium 4  The first Intel seventh-generation processor, it's based on a new 32-bit microarchitecture that operates at higher clock speeds because of hyper pipelined technology, a rapid execution engine, a 400MHz system bus, and an execution trace cache. The 400MHz system bus is a quad-pumped bus running off a 100MHz system clock, making 3.2Gbps data transfer rates possible. The advanced transfer cache is a 256KB, on-die Level 2 cache with increased bandwidth over previous microarchitectures. The floating-point and multimedia units have been improved by making the registers 128 bits wide and adding a separate register for data movement. Finally, SSE2 adds 144 new instructions for double-precision floating-point, SIMD integer, and memory management. The original version for Socket 423 was codenamed Willamette, whereas the latest Socket 478 version was codenamed Northwood.

Pentium II  An Intel sixth-generation processor similar to the Pentium Pro but with MMX capabilities and SEC cartridge packaging technology. Includes L2 cache running at half-core speed.

Pentium III  An Intel sixth-generation processor similar to the Pentium II but with SSE (Streaming SIMD Extensions) added. Later PIII models (codenamed Coppermine) include on-die L2 cache running at full core speed. It's available in both cartridge (Slot 1) and chip package (Socket 370) versions.

Pentium Pro  An Intel sixth-generation (P6) processor with 32-bit registers, a 64-bit data bus, and a 36-bit address bus. The Pentium Pro has the same segmented Level 1 cache as the Pentium but also includes a 256KB, 512KB, or 1MB of L2 cache on a separate die inside the processor package. The Pentium Pro includes an FPU or math coprocessor. It is backward compatible with the Pentium and can operate in real, protected, and virtual real modes. The Pentium Pro fits into Socket 8.

peripheral  Any piece of equipment used in computer systems that is an attachment to the computer. Disk drives, terminals, and printers are all examples of peripherals.
**persistence**  In a monitor, the quality of the phosphor chemical that indicates how long the glow caused by the electrons striking the phosphor will remain onscreen.

**petabyte (P)**  A measure of disk capacity equaling 1,000,000,000,000,000 bytes.

**PGA**  1) Pin grid array. A chip package that has a large number of pins on the bottom designed for socket mounting. 2) Professional graphics adapter. A limited-production, high-resolution graphics card for XT and AT systems from IBM.

**phosphor**  A layer of electroluminescent material applied to the inside face of a cathode-ray tube (CRT). When bombarded by electrons, the material fluoresces, and after the bombardment stops it phosphoresces.

**phosphorescence**  The emission of light from a substance after the source of excitation has been removed.

**Photo CD**  A technology developed by Eastman Kodak and Philips that stores photographic images on a CD-R recordable compact disc. Images stored on the Photo CD can have resolutions as high as 2048 × 3072 pixels. Up to 100 true-color images (24-bit color) can be stored on one disc. Photo CD images are created by scanning film and digitally recording the images on compact discs. The digitized images are indexed (given a 4-digit code), and thumbnails of each image on the disc are shown on the front of the case along with its index number. Multisession capability enables several rolls of film to be added to a single disc on different occasions.

**photolithography**  The photographic process used in electronic chip manufacturing that creates transistors and circuit and signal pathways in semiconductors by depositing different layers of various materials on the chip.

**photoresist**  A chemical used to coat a silicon wafer in the semiconductor manufacturing process that makes the silicon sensitive to light for photolithography.

**physical drive**  A single disk drive. DOS defines logical drives, which are given a specifier, such as C: or D:. A single physical drive can be divided into multiple logical drives. Conversely, special software can span a single logical drive across two physical drives.

**Physical Layer**  See OSI.

**physical unit number**  See PUN.

**Picture CD**  A simplified version of Photo CD that stores scanned images from a single roll of film on a CD-R disc. Images on Picture CDs, unlike those on Photo CDs, are stored in the industry-standard JPEG file format and can be opened with most photo-editing programs.

**PIF (program information file)**  A file that contains information about a non-Windows application specifying optimum settings for running the program under Windows 3.x. These are called property sheets in 32-bit Windows.

**pin**  1) The lead on a connector, chip, module, or device. 2) Personal identification number. A personal password used for identification purposes.

**pin compatible**  Chips having the same pinout functions. For example, a VIA C3 processor is pin compatible with an Intel Celeron (Socket 370 version).

**pinout**  A listing of which pins have which functions on a chip, socket, slot, or other connector.

**PIO mode (programmed input/output mode)**  The standard data transfer modes used by IDE drives that use the processor’s registers for data transfer. This is in contrast with DMA modes, which transfer data directly between main memory and the device. The slowest PIO mode is 0, and the fastest PIO mode is mode 4 (16.66MBps). Faster modes use Ultra DMA transfers. See also Ultra DMA.

**pipeline**  A path for instructions or data to follow.

**pixel**  A mnemonic term meaning picture element. Any of the tiny elements that form a picture on a video display screen. Also called a pel.

**pixel shader**  A small program that controls the appearance of individual pixels in a 3D image. Most recent mid-range and high-end GPUs such as NVIDIA’s GeForce 3 and GeForce 4 Ti series and the ATI 8xxx and 9xxx series have built-in pixel shaders. See also GPU, hardware shader, and vertex shader.

**PKZIP**  The original ZIP-format compression/decompression program developed by the late Phil Katz. His company, PKWARE, continues to develop PKZIP for popular operating systems, including Windows.

**planar board**  A term equivalent to motherboard, used by IBM in some of its literature.

**plasma display**  A display technology that uses plasma (electrically charged gas) to illuminate each pixel. Plasma displays are much thinner than conventional CRT displays but are much more expensive than CRTs or LCD displays. Several vendors now sell HDTV plasma displays that can also be connected to computers with VGA or DVI video connectors.

**plated media**  Hard disk platters plated with a form of thin metal film medium on which data is recorded.

**platter**  A disk contained in a hard disk drive. Most drives have two or more platters, each with data recorded on both sides.

**PLCC (plastic leaded-chip carrier)**  A chip-carrier package with J-leads around the perimeter of the package.
Plug and Play (PnP)  A hardware and software specification developed by Intel that enables a PnP system and PnP adapter cards to automatically configure themselves. PnP cards are free from switches and jumpers and are configured via the PnP BIOS in the host system, or via supplied programs for non-PnP systems. PnP also allows the system to detect and configure external devices, such as monitors, modems, and devices attached to USB or IEEE-1394 ports. Windows 9x, Me, 2000, and XP all support PnP devices.

polling  A communications technique that determines when a device is ready to send data. The system continually interrogates polled devices in a round-robin sequence. If a device has data to send, it sends back an acknowledgment and the transmission begins. Contrasts with interrupt-driven communications, in which the device generates a signal to interrupt the system when it has data to send. Polling enables two devices that would normally have an IRQ conflict to coexist because the IRQ is not used for flow control.

port  Plug or socket that enables an external device, such as a printer, to be attached to the adapter card in the computer. Also a logical address used by a microprocessor for communication between it and various devices.

port address  One of a system of addresses used by the computer to access devices such as disk drives or printer ports. You might need to specify an unused port address when installing any adapter boards in a system unit.

port replicator  For mobile computers, a device that plugs into the laptop and provides all the ports for connecting external devices. The advantage of using a port replicator is that the external devices can be left connected to the replicator and the mobile computer connected to them all at once by connecting to the replicator, rather than connecting to each individual device. A port replicator differs from a docking station in that the latter can provide additional drive bays and expansion slots not found in port replicators. Traditionally, port replicators have plugged into a proprietary bus on the rear of a portable computer, but so-called universal models might attach to the PC Card (PCMCIA) slot or to a USB port.

portable computer  A computer system smaller than a transportable system but larger than a laptop system. Very few systems in this form factor are sold today, but companies such as Dolch still produce them. Most portable systems conform to the lunchbox style popularized by Compaq or the briefcase style popularized by IBM, each with a fold-down (removable) keyboard and built-in display. These systems characteristically run on AC power and not on batteries, include several expansion slots, and can be as powerful as full desktop systems.

POS (Programmable Option Select)  The Micro Channel Architecture’s POS eliminates switches and jumpers from the system board and adapters by replacing them with programmable registers. Automatic configuration routines store the POS data in a battery-powered CMOS memory for system configuration and operations. The configuration utilities rely on adapter description files (ADF) that contain the setup data for each card.

POST (power on self test)  A series of tests run by the computer at power-on. Most computers scan and test many of their circuits and sound a beep from the internal speaker if this initial test indicates proper system performance.

PostScript  A page-description language developed primarily by John Warnock of Adobe Systems for converting and moving data to the laser-printed page. Instead of using the standard method of transmitting graphics or character information to a printer and telling it where to place dots one by one on a page, PostScript provides a way for the laser printer to interpret mathematically a full page of shapes and curves. Adobe Acrobat converts PostScript output files into files that can be read by users with varying operating systems. See also Acrobat.

POTS (plain old telephone service)  Standard analog telephone service.

power management  Systems used initially in mobile computers (and now also used in desktop systems) to decrease power consumption by turning off or slowing down devices during periods of inactivity. See also APM.

power supply  An electrical/electronic circuit that supplies all operating voltage and current to the computer system.

PPGA (plastic pin grid array)  A chip-packaging form factor used by Intel as an alternative to traditional ceramic packaging.

PPP (Point-to-Point Protocol)  A protocol that enables a computer to use the Internet with a standard telephone line and high-speed modem. PPP has largely replaced the Serial Line Internet Protocol (SLIP) because it supports line sharing and error detection.

precompensation  A data write modification required by some older drives on the inner cylinders to compensate for the higher density of data on the (smaller) inner cylinders.

Presentation Layer  See OSI.

primary partition  An ordinary, single-volume bootable partition. See also extended partition.

printer  A device that records information visually on paper or other material.

processor  See microprocessor.
processor speed  The clock rate at which a microprocessor processes data. A typical Pentium 4 processor, for example, operates at 2GHz (2 billion cycles per second).

program  A set of instructions or steps telling the computer how to handle a problem or task.

PROM (programmable read-only memory)  A type of memory chip that can be programmed to store information permanently—information that can’t be erased. Also referred to as OTP for one-time programmable.

proprietary  Anything invented by one company and that uses components available from only that one company. Especially applies to cases in which the inventing company goes to lengths to hide the specifications of the new invention or to prevent other manufacturers from making similar or compatible items. The opposite of standard or open architecture.

Computers with nonstandard components that are available from only the original manufacturer, such as Apple Macintosh systems, are known as proprietary.

protected mode  A mode available in all Intel and compatible processors except the first-generation 8086 and 8088. In this mode, memory addressing is extended beyond the 1MB limits of the 8088 and real mode and restricted protection levels can be set to trap software crashes and control the system.

protocol  A system of rules and procedures governing communications between two or more devices. Protocols vary, but communicating devices must follow the same protocol to exchange data. The data format, readiness to receive or send, error detection, and error correction are some of the operations that can be defined in protocols.

proxy server  A computer that acts as a gateway between the computers on a network and the Internet and also provides page caching and optional content filtering and firewall services to the network. Some home network software solutions for Internet sharing, such as WinProxy, use a proxy server.

PS/2 mouse  A mouse designed to plug into a dedicated mouse port (a round, 6-pin DIN connector) on the motherboard, rather than plugging into a serial port. The name comes from the fact that this port was first introduced on the IBM PS/2 systems.

PUN (physical unit number)  A term used to describe a device attached directly to the SCSI bus. Also known as a SCSI ID. As many as eight SCSI devices can be attached to a single SCSI bus, and each must have a unique PUN or ID assigned from 7 to 0. Normally, the SCSI host adapter is assigned the highest-priority ID, which is 7. A bootable hard disk is assigned an ID of 0, and other nonbootable drives are assigned higher priorities.

QAM (quadrature amplitude modulation)  A modulation technique used by high-speed modems that combines both phase and amplitude modulation. This technique enables multiple bits to be encoded in a single time interval.

QDR (quad data rate)  A high-speed SDRAM technology ([www.qdramsram.com](http://www.qdramsram.com)) that uses separate input and output ports with a DDR interface to enable four pieces of data to be processed at the same time. See also DDR.

QIC (Quarter-Inch Committee)  An industry association that sets hardware and software standards for tape-backup units that use quarter-inch-wide tapes. QIC, QIC-Wide, Travan, and Travan NS drives are all based on QIC standards.

Quantum  Formerly a major maker of hard disk drives and now a major maker of attached network storage devices. Quantum-brand disk drives are now sold and supported by Maxtor.

QWERTY keyboard  The standard typewriter or computer keyboard, with the characters Q, W, E, R, T, and Y on the top row of alpha keys. Because of the haphazard placement of characters, this keyboard can hinder fast typing.

RAID (redundant array of independent or inexpensive disks)  A storage unit that employs two or more drives in combination for fault tolerance and greater performance, used mostly in file server applications. Originally used only with SCSI drives and host adapters, many motherboards now feature IDE RAID implementations.

rails  Plastic or metal strips attached to the sides of disk drives mounted in IBM ATs and compatibles so that the drives can slide into place. These rails fit into channels in the side of each disk drive bay position and might be held in position with screws or snap into place.

RAM (random-access memory)  All memory accessible at any instant (randomly) by a microprocessor.

RAM disk  A “phantom disk drive” in which a section of system memory (RAM) is set aside to hold data, just as though it were a number of disk sectors. To an operating system, a RAM disk looks and functions like any other drive.

RAMBUS Dynamic RAM  See RDRAM.

RAMDAC (random-access memory digital-to-analog converter)  A special type of DAC found on video cards. RAMDACs use a trio of DACs—one each for red, green, and yellow—to convert image data into a picture. RAMDACs were formerly separate chips but are now integrated into the 3D accelerator chips on most recent video cards.
random-access file  A file in which all data elements (or records) are of equal length and written in the file end to end, without delimiting characters between. Any element (or record) in the file can be found directly by calculating the record's offset in the file.

random-access memory  See RAM.

raster  A pattern of horizontal scanning lines normally on a computer monitor. An electromagnetic field causes the beam of the monitor's tube to illuminate the correct dots to produce the required characters.

raster graphics  A technique for representing a picture image as a matrix of dots. It is the digital counterpart of the analog method used in TV. Several raster graphics standards exist, including PCX, TIFF, BMP, JPEG, and GIF.

RCA jack  Also called a phono connector. A plug and socket for a two-wire coaxial cable used to connect audio and video components. The plug is a 1/8" thick prong that sticks out 5/16" from the middle of a cylinder.

RDRAM (Rambus DRAM)  A high-speed dynamic RAM technology developed by Rambus, Inc., which is supported by Intel's 1999 and later motherboard chipsets. RDRAM transfers data at 1GBps or faster, which is significantly faster than SDRAM and other technologies and which is capable of keeping up with future-generation high-speed processors. Memory modules with RDRAM chips are called RIMMs (Rambus inline memory modules). Rambus licenses its technology to other semiconductor companies, who manufacture the chips and RIMMs. RDRAMs are used by some of Intel's mid-range and high-end chipsets for the Pentium III and Pentium 4 desktop processors and their server counterparts.

read-only file  A file whose attribute setting in the file's directory entry tells DOS not to allow software to write into or over the file.

read-only memory  See ROM.

read/write head  A tiny magnet that reads and writes data on a disk track.

real mode  A mode available in all Intel 8086-compatible processors that enables compatibility with the original 8086. In this mode, memory addressing is limited to 1MB.

real-time  The actual time in which a program or an event takes place. In computing, real-time refers to an operating mode under which data is received and processed and the results returned so quickly that the process appears instantaneous to the user. The term also is used to describe the process of simultaneous digitization and compression of audio and video information.

reboot  The process of restarting a computer and reloading the operating system.

Red Book  More commonly known as Compact Disc-Digital Audio (CD-DA), one of four compact disc standards. Red Book got its name from the color of the manual used to describe the CD-Audio specifications. The Red Book audio standard requires that digital audio be sampled at a 44.1KHz sample rate using 16 bits for each sample. This is the standard used by audio CDs and many CD-ROMs.

refresh cycle  A cycle in which the computer accesses all memory locations stored by DRAM chips so that the information remains intact. DRAM chips must be accessed several times per second; otherwise, the information fades.

refresh rate  Another term for the vertical scan frequency of monitors.

register  Storage area in memory having a specified storage capacity—such as a bit, byte, or computer word—and intended for a special purpose.

Registry  The system configuration files used by Windows 9x, Windows Me, Windows NT, Windows 2000, and Windows XP to store settings about installed hardware and drivers, user preferences, installed software, and other settings required to keep Windows running properly. Replaces the WIN.INI and SYSTEM.INI files from Windows 3.x. The Registry structure varies between Windows versions.

remote digital loopback  A test that checks the phone link and a remote modem's transmitter and receiver. Data entered from the keyboard is transmitted from the initiating modem, received by the remote modem's receiver, looped through its transmitter, and returned to the local screen for verification.

remote echo  A copy of the data received by the remote system, returned to the sending system, and displayed onscreen. A function of the remote system.

rendering  Generating a 3D image that incorporates the simulation of lighting effects, such as shadows and reflection.

resolution  1) A reference to the size of the pixels used in graphics. In medium-resolution graphics, pixels are large. In high-resolution graphics, pixels are small. 2) A measure of the number of horizontal and vertical pixels that can be displayed by a video adapter and monitor.

reverse engineering  The act of duplicating a hardware or software component by studying the functions of the component and designing a different one that has the same functions.
RFI (radio frequency interference)  A high-frequency signal radiated by improperly shielded conductors, particularly when signal path lengths are comparable to or longer than the signal wavelengths. The FCC now regulates RFI in computer equipment sold in the U.S. under FCC Regulations, Part 15, Subpart J.

RGB (red green blue)  A type of computer color display output signal comprised of separately controllable red, green, and blue signals; as opposed to composite video, in which signals are combined prior to output. RGB monitors offer much higher resolution and sharper pictures than composite monitors.

ribbon cable  Flat cable with wires running in parallel, such as those used for internal IDE or SCSI.

Rich Text Format (RTF)  A universal file format suitable for exchanging formatted text files between different word processing and page layout programs.

RIMM (Rambus inline memory module)  A type of memory module made using RDRAM chips. See also RDRAM.

RISC (reduced instruction set computer)  Differentiated from CISC, the complex instruction set computer. RISC processors have simple instruction sets requiring only one or a few execution cycles. These simple instructions can be used more effectively than CISC systems with appropriately designed software, resulting in faster operations. See also CISC.

RJ-11  The standard two-wire connector type used for single-line telephone connections.

RJ-14  The standard four-wire connector type used for two-line telephone connections.

RJ-45  A standard connector type used in networking with twisted-pair cabling. Resembles an RJ-11/14 telephone jack, but RJ-45 is larger with more wires.

RLL (run-length limited)  A type of encoding that derives its name from the fact that the techniques used limit the distance (run length) between magnetic flux reversals on the disk platter. Several types of RLL encoding techniques exist, although only two are commonly used. (1,7) RLL encoding increases storage capacity by about 30% over MFM encoding and is most popular in the very highest capacity drives due to a better window margin, whereas (2,7) RLL encoding increases storage capacity by 50% over MFM encoding and is used in the majority of RLL implementations. Most IDE, ESDI, and SCSI hard disks use one of these forms of RLL encoding.

RMA number (return-merchandise authorization number)  A number given to you by a vendor when you arrange to return an item for repairs. Used to track the item and the repair.

ROM (read-only memory)  A type of memory that has values permanently or semipermanently burned in. These locations are used to hold important programs or data that must be available to the computer when the power initially is turned on.

ROM BIOS (read-only memory basic input/output system)  A BIOS encoded in a form of read-only memory for protection.

root directory  The main directory of any hard or floppy disk. It has a fixed size and location for a particular disk volume and can’t be resized dynamically the way subdirectories can.

router  A device that is used to connect various networks, intelligently routing information between them. It is used to internetwork similar and dissimilar networks and can select the most expedient route based on traffic load, line speeds, costs, and network failures. Routers use forwarding tables to determine which packets should be forwarded between the connected networks. A cable or DSL modem is an example of a simple router that connects the Internet to your own network. Many routers include firewall capability to block suspect packets from being transmitted between networks.

routine  Set of frequently used instructions. It can be considered as a subdivision of a program with two or more instructions that are related functionally.

RS-232  An interface introduced in August 1969 by the Electronic Industries Association. The RS-232 interface standard provides an electrical description for connecting peripheral devices to computers. Originally, RS-232 (serial) ports on computers used a 25-pin interface, but starting with the IBM AT, most use a 9-pin interface.

RTC (real-time clock)  A battery-powered clock included on the motherboard of 286-class and newer computers. The contents of the RTC are read at startup time to provide the time display in the operating system’s clock. It’s often part of the NVRAM chip.

S/PDIF (Sony Philips Digital Interface)  Provides digital I/O on high-end sound cards and multimedia-capable video cards. Might use either an RCA jack or optical jack; some devices support both types of S/PDIF connectors.

S-Video (Y/C)  Type of video signal used in the Hi8 and S-VHS videotape formats in which the luminance and chrominance (Y/C) components are kept separate, providing greater control and quality of each image. S-video transmits luminance and color portions separately, thus avoiding the NTSC encoding process and its inevitable loss of picture quality.
SATA (Serial ATA)  A high-speed serial interface designed to replace the current parallel ATA and UltraATA drive interface standards. Serial ATA 1.0 uses a seven-wire data/ground cable and supports direct point-to-point connections to host adapters at initial speeds of up to 150MBps, which is faster than UltraATA-133. Serial ATA II is a version of the SATA standard designed for servers. See also Ultra DMA.

scan codes  The hexadecimal codes actually sent by the keyboard to the motherboard when a key is pressed.

scan lines  The parallel lines across a video screen, along which the scanning spot travels in painting the video information that makes up a monitor picture. NTSC systems use 525 scan lines to a screen; PAL systems use 625.

ScanDisk  The default Windows 9x/Me drive testing program; might be referred to as error checking in the Drive properties screen. Windows NT, Windows 2000, and Windows XP use CHKDSK to test drives.

scanner  A device that reads an image and converts it into computer data.

scanning frequency  A monitor measurement that specifies how often the image is refreshed. See also vertical scan frequency.

scratch disk  A disk that contains no useful information and can be used as a test disk. IBM has a routine on the Advanced Diagnostics disks that creates a specially formatted scratch disk to be used for testing floppy drives.

SCSI (small computer system interface)  A standard originally developed by Shugart Associates (then called SASI for Shugart Associates System Interface) and later approved by ANSI in 1986. SCSI-2 (now called SPI-2) was approved in 1994, and SCSI-3 (now called SPI-3) began the approval process in 1995. Ultra SCSI-4 (now called SPI-4) is currently in the development process. 8-bit (narrow) versions of SCSI typically use a 50-pin connector and permit multiple devices (up to 8 including the host) to be connected in daisy-chain fashion. Some low-cost narrow SCSI devices might use a 25-pin connector. Wide and Ultra Wide versions of SCSI use a 68-pin connector and can support up to 16 devices including the host.

SDLC (Synchronous Data Link Control)  A protocol developed by IBM for software applications and communicating devices operation in IBM’s Systems Network Architecture (SNA). Defines operations at the link level of communications—for example, the format of data frames exchanged between modems over a phone line.

SDRAM (synchronous DRAM)  RAM that runs at the same speed as the main system bus.

SEC (single edge contact)  An Intel processor packaging design in which the processor and optional L2 cache chips are mounted on a small circuit board (much like an oversized memory SIMM), which might be sealed in a metal and plastic cartridge. The cartridge is then plugged into the motherboard through an edge connector called Slot 1 or Slot 2, which looks similar to an adapter card slot. Several variations to the SEC cartridge form factor exist: The single edge contact cartridge (SECC) has a cover and a thermal plate; the single edge contact cartridge 2 (SECC2) has a cover, but no thermal plate; and the single edge processor package (SEP), which is used only with Celeron processors) has no cover or thermal plate. In implementations with no thermal plate, the heatsink is attached directly to the processor package or die.

SECC (single edge contact cartridge)  See SEC.

SECC2 (single edge contact cartridge 2)  See SEC.

sector  A section of one track defined with identification markings and an identification number. Most sectors hold 512 bytes of data.

security software  Utility software that uses a system of passwords and other devices to restrict an individual’s access to subdirectories and files.

seek time  The amount of time required for a disk drive to move the heads across one third of the total number of cylinders. Represents the average time it takes to move the heads from one cylinder to another randomly selected cylinder. Seek time is a part of the average access time for a drive.

self-extracting file  An archive file that contains its own extraction program. Open it in a file manager, such as Windows Explorer, to uncompress the files it contains. Because all types of files, including trojans, can be distributed as .exe files (the extension also used by self-extracting files), consider using a program such as WinZip to examine the contents of an .exe file before you open it.

semiconductor  A substance, such as germanium or silicon, whose conductivity is poor at low temperatures but is improved by minute additions of certain substances or by the application of heat, light, or voltage. Depending on the temperature and pressure, a semiconductor can control a flow of electricity. Semiconductors are the basis of modern electronic-circuit technology.
SEPP (single edge processor package)  See SEC.
sequence  A software program that controls MIDI file messages and keeps track of music timing. Because MIDI files store note instructions instead of actual sounds, a sequencer is needed to play, record, and edit MIDI sounds. Sequence programs enable recording and playback of MIDI files by storing the instrument, note pitch (frequency), duration (in real-time) that each note is held, and loudness (amplitude) of each musical or sound-effect note.

sequential file  A file in which varying-length data elements are recorded end to end, with delimiting characters placed between each element. To find a particular element, you must read the whole file up to that element.

serial  The transfer of data characters one bit at a time, sequentially, using a single electrical path.

Serial ATA  See SATA.

serial mouse  A mouse designed to connect to a computer’s serial port.

serial port  An I/O connector used to connect to serial devices. See also RS-232.

server  A computer in a network that enables resources such as files and printers to be shared by multiple users.

servo  The mechanism in a drive that enables the head positioner to adjust continuously so that it is precisely placed above a given cylinder in the drive.

data  Magnetic markings written on disk platters to guide the read/write heads in drives that use voice-coil actuators.

session (single or multisession)  A term used in CD-ROM recording to describe a recording event. In a single session, data is recorded on a CD-ROM and an index is created. If additional space is left on the disc, another session can be used to record additional files along with another index. Some older CD-ROM drives do not expect additional recording sessions and therefore are incapable of reading the additional session data on the disc. The advent of Kodak’s Photo CD propelled the desire for multisession CD-ROM XA (extended architecture) drives.

Session Layer  See OSI.

settling time  The time required for read/write heads to stop vibrating after they have been moved to a new track.

shadow mask  A thin screen full of holes that adheres to the inside of a color CRT. The electron beam is aimed through the holes in the mask onto the phosphor dots. See also aperture grille.

shadow RAM  A copy of a system’s slower-access ROM BIOS placed in faster-access RAM, usually during the startup or boot procedure. This setup enables the system to access BIOS code without the penalty of additional wait states required by the slower ROM chips. Also called shadow ROM or ROM shadowing.

shell  The generic name of any user interface software. COMMAND.COM is the standard shell for DOS; 32-bit Windows uses the Windows Explorer as a graphical shell and either COMMAND.COM (Windows 9x/Me) or CMD.EXE (Windows NT/2000/XP) as the command-line shell.

shielded twisted-pair (STP)  Unshielded twisted-pair (UTP) network cabling with a metal sheath or braid around it to reduce interference, usually used in Token-Ring networks.

shock rating  A rating (usually expressed in G force units) of how much shock a disk drive can sustain without damage. Usually two specifications exist for a drive powered on or off.

signal-to-noise (S/N) ratio  The strength of a video or an audio signal in relation to interference (noise). The higher the S/N ratio, the better the quality of the signal. The latest high-end sound cards have an S/N ratio of 100:1.

silicon  The base material for computer chips. An element, silicon (symbol Si) is contained in the majority of rock and sand on earth and is the second most abundant element on the planet next to oxygen.

SIMD (single instruction multiple data)  The term used to describe the MMX and SSE instructions added to the Intel processors. These instructions can process matrices consisting of multiple data elements with only a single instruction, enabling more efficient processing of graphics and sound data.

SIMM (single inline memory module)  An array of memory chips on a small PC board with a single row of I/O contacts. SIMMs commonly have 30 or 72 connectors.

single-ended  An electrical signaling method in which a single line is referenced by a ground path common to other signals. In a single-ended bus intended for moderately long distances, commonly one ground line exists between groups of signal lines to provide some resistance to signal crosstalk. Single-ended signals require only one driver or receiver pin per signal, plus one ground pin per group of signals. Single-ended signals are vulnerable to common mode noise and crosstalk but are much less expensive than differential signaling methods.

SIP (single inline package)  A DIP-like package with only one row of leads.

skinny dip  Twenty-four- and twenty-eight-position DIP devices with .300” row-to-row centerlines.

sleep  See suspend.

SLIP (Serial Line Internet Protocol)  An Internet protocol that is used to run the Internet Protocol (IP) over serial lines, such as telephone circuits. IP enables a packet to traverse multiple networks on the way to its final destination. Largely replaced by PPP. See also PPP.
**slot** A physical connector on a motherboard to hold an expansion card, SIMMs and DIMMs, or a processor card in place and make contact with the electrical connections.

**Slot 1** The motherboard connector designed by Intel to accept its SEC cartridge processor design used by the Pentium II and early Celeron and Pentium III processors.

**Slot 2** A motherboard connector for Pentium II and Pentium III Xeon processors intended mainly for file server applications. Slot 2 systems support up to four-way symmetric multiprocessing.

**SMART (self-monitoring analysis and reporting technology)** An industry standard for advance reporting of imminent hard drive failure. When this feature is enabled in the BIOS and a SMART-compliant hard drive is installed, detected problems can be reported to the computer. This enables the user to replace a drive before it fails. Programs such as Norton System Works and Norton Utilities are compatible with these status messages.

**SMBIOS** A BIOS that incorporates system management functions and reporting compatibility with the Desktop Management Interface (DMI).

**SMPTE time code** An 80-bit standardized edit time code adopted by SMPTE, the Society of Motion Picture and Television Engineers. The SMPTE time code is a standard used to identify individual video frames in the video-editing process. SMPTE time code controls such functions as play, record, rewind, and forward of video tapes. SMPTE time code displays video in terms of hours, minutes, seconds, and frames for accurate video editing.

**snow** A flurry of bright dots that can appear anywhere onscreen on a monitor.

**SO-J (small outline J-lead)** A small DIP package with J-shaped leads for surface mounting or socketing.

**socket** A receptacle, usually on a motherboard although sometimes also found on expansion cards, into which processors or chips can be plugged.

**Socket 1-8** The Intel specifications for eight different sockets to accept various Intel processors in the 486, Pentium, and Pentium Pro families.

**Socket 370** A 370-pin socket used by socketed versions of the Celeron and Pentium III and the VIA C3 processors.

**Socket 423** The socket used by the initial versions of the Pentium 4.

**Socket 462** See *Socket A*.

**Socket 478** A 478-pin socket used by the Northwood versions of the Pentium 4.

**Socket 603** A 603-pin socket used by Intel Xeon processors based on the Pentium 4 design.

**Socket A** A 462-pin socket used by socketed versions of the AMD Athlon and Duron.

**SODIMM (small outline dual inline memory module)** An industry-standard 144-pin memory module designed for use primarily in laptop and portable computers.

**soft error** An error in reading or writing data that occurs sporadically, usually because of a transient problem, such as a power fluctuation.

**software** A series of instructions loaded in the computer’s memory that instructs the computer in how to accomplish a problem or task.

**sound card** An adapter card with sound-generating capabilities.

**South Bridge** The Intel term for the lower-speed component in the chipset that has always been a single individual chip; it has been replaced in the 8xx-series chipsets by the ICH. The South Bridge connects to the 33MHz PCI bus and contains the IDE interface ports and the interface to the 8MHz ISA bus (when present). It also typically contains the USB interface and even the CMOS RAM and real-time clock functions. The South Bridge contains all the components that make up the ISA bus, including the interrupt and DMA controllers. See also *chipset, ICH, MCH,* and *North Bridge*.

**SPI (SCSI parallel interface)** Alternative name for common SCSI standards. See also *SCSI*.

**spindle** The central post on which a disk drive’s platters are mounted.

**spindle count** In notebook and laptop computers with interchangeable drives, spindle count refers to how many drives can be installed and used at the same time.

**splitter** Used in DSL and cable modem service to separate Internet signals from those used by the existing telephone (DSL) or cable TV service.

**SRAM (static random access memory)** A form of high-speed memory. SRAM chips do not require a refresh cycle like DRAM chips and can be made to operate at very high access speeds. SRAM chips are very expensive because they normally require six transistors per bit. This also makes the chips larger than conventional DRAM chips. SRAM is volatile, meaning it will lose data with no power. SRAMs are often used for cache memory.

**SSE (streaming SIMD extensions)** The name given by Intel for the 70 new MMX-type instructions added to the Pentium III processor when it was introduced. See also *MMX* and *SIMD*.

**ST-506/412** A hard disk interface invented by Seagate Technology and introduced in 1980 with the ST-506 SMB hard drive. IDE drives emulate this disk interface.
stack A device in the power line that feeds the computer and provides protection against voltage spikes and other transients.

suspend Refers to a level of power management in which substantial power reduction is achieved by the display or other components. The components can have a longer recovery time from this state than from the standby state.

SVGA (Super VGA) Refers to a video adapter or monitor capable of 800×600 resolution.

SWEDAC (Swedish Board for Technical Accreditation) Regulatory agency establishing standards such as MPR1 and MPR2, which specify maximum values for both alternating electric fields and magnetic fields and provide monitor manufacturers with guidelines in creating low-emission monitors.

switch Also called a switching hub, it's a type of hub that reads the destination address of each packet and then forwards the packet to only the correct port, minimizing traffic on other parts of the network. Unlike a regular hub, which wastes network bandwidth by copying packets to all ports, a switch forwards packets to only their intended recipients, immediately reducing network traffic jams and improving overall efficiency for the entire network. Many switches also support full-duplex service, effectively doubling the speed of full-duplex network cards attached to the switch. See also hub.

SXGA (Super XGA) Refers to a video adapter or monitor capable of 1280×1024 or greater resolution.

synchronous communication A form of communication in which blocks of data are sent at strictly timed intervals. Because the timing is uniform, no start or stop bits are required. Compare with asynchronous communication. Some mainframes support only synchronous communication unless a synchronous adapter and appropriate software have been installed. See also asynchronous communication.

system crash A situation in which the computer freezes up and refuses to proceed without rebooting. Usually caused by faulty software, it's unlike a hard disk crash—no permanent physical damage occurs.

system files Files with the system attribute. Usually, the hidden files that are used to boot the operating system. The MS-DOS and Windows 9x system files include IO.SYS and MSDOS.SYS; the IBM DOS system files are IBMBIO.COM and IBMDOS.COM.

System Management Mode (SMM) Circuitry integrated into Intel processors that operates independently to control the processor's power use based on its activity level. It enables the user to specify time intervals after which the CPU will be powered down partially or fully and also supports the suspend/resume feature that enables instant power-on and power-off.
**tape drive** Any data storage drive that uses tape as the storage medium.

**target** A device attached to a SCSI bus that receives and processes commands sent from another device (the initiator) on the SCSI bus. A SCSI hard disk is an example of a target.

**TCM (Trellis-coded modulation)** An error-detection and correction technique employed by high-speed modems to enable higher-speed transmissions that are more resistant to line impairments.

**TCO** 1) Refers to the Swedish Confederation of Professional Employees, which has set stringent standards for devices that emit radiation. See also MPR. 2) Total cost of ownership. The cost of using a computer. It includes the cost of the hardware, software, and upgrades as well as the cost of the in-house staff and consultants who provide training and technical support.

**TCP (tape carrier package)** A method of packaging processors for use in portable systems that reduces the size, power consumed, and heat generated by the chip. A processor in the TCP form factor is essentially a raw die encased in an oversized piece of polyamide film. The film is laminated with copper foil that is etched to form the leads that will connect the processor to the motherboard.

**TCP port number** Logical port numbers used by TCP to communicate between computers—for example, Web browsing (http://) uses TCP port 80. POP3 email uses TCP port 110. Some firewalls require you to manually configure open TCP port numbers to allow certain processes and programs to work.

**TCP/IP (Transmission Control Protocol/Internet Protocol)** A set of protocols developed by the U.S. Department of Defense (DoD) to link dissimilar computers across many types of networks. This is the primary protocol used by the Internet.

**temporary backup** A second copy of a work file, usually having the extension BAK. Created by application software so you easily can return to a previous version of your work.

**temporary file** A file temporarily (and usually invisibly) created by a program for its own use.

**tera** A multiplier indicating one trillion (1,000,000,000,000) of some unit. Abbreviated as T or T. A binary tera (now called a tebi) is 1,099,511,627,776.

**terabyte (T)** A unit of information storage equal to 1,000,000,000 bytes.

**terminal** A device whose keyboard and display are used for sending and receiving data over a communications link. Differs from a microcomputer in that it has no internal processing capabilities. Used to enter data into or retrieve processed data from a system or network.

**terminal mode** An operational mode required for microcomputers to transmit data. In terminal mode, the computer acts as though it were a standard terminal, such as a teletypewriter, rather than a data processor. Keyboard entries go directly to the modem, whether the entry is a modem command or data to be transmitted over the phone lines. Received data is output directly to the screen. The more popular communications software products control terminal mode and enable more complex operations, including file transmission and saving received files.

**terminator** Hardware or circuits that must be attached to or enabled at both ends of an electrical bus. Functions to prevent the reflection or echoing of signals that reach the ends of the bus and to ensure that the correct impedance load is placed on the driver circuits on the bus. Most commonly used with the SCSI bus and Thin Ethernet.

**TFT (thin film transistor)** The highest quality and brightest LCD color display type. A method for packaging one–four transistors per pixel within a flexible material that is the same size and shape as the LCD display, which enables the transistors for each pixel to lie directly behind the liquid crystal cells they control.

**thick Ethernet** See 10BASE-5.

**thin Ethernet** See 10BASE-2.

**thin-film media** Hard disk platters that have a thin film (usually three-millionths of an inch) of medium deposited on the aluminum substrate through a sputtering or plating process.

**thinnet** See 10BASE-2.

**through-hole** Chip carriers and sockets equipped with leads that extend through holes in a PC board.

**throughput** The amount of user data transmitted per second without the overhead of protocol information, such as start and stop bits or frame headers and trailers.

**thumb drive** See keychain drive.

**TIFF (tagged image file format)** A way of storing and exchanging digital image data. Developed by Aldus Corporation, Microsoft Corporation, and major scanner vendors to help link scanned images with the popular desktop publishing applications. Supports three main types of image data: black-and-white data, halftones or dithered data, and grayscale data. Compressed TIFF files are stored using lossless compression.

**time code** A frame-by-frame address code time reference recorded on the spare track of a videotape or inserted in the vertical blanking interval. The time code is an eight-digit number encoding time in hours, minutes, seconds, and video frames.
Token-Ring  A type of local area network in which the workstations relay a packet of data called a token in a logical ring configuration. When a station wants to transmit, it takes possession of the token, attaches its data, and then frees the token after the data has made a complete circuit of the electrical ring. Transmits at speeds of 16Mbps. Because of the token-passing scheme, access to the network is controlled, unlike the slower 10BASE-X Ethernet system in which collisions of data can occur, which wastes time. The Token-Ring network uses shielded twisted-pair wiring, which is cheaper than the coaxial cable used by 10BASE-2 and 10BASE-5 Ethernet and ARCnet.

toner  The ultrafine, colored, plastic powder used in laser printers, LED printers, and photocopying to produce the image on paper.

tower  A personal computer that normally sits on the floor and is mounted vertically rather than horizontally.

TPI (tracks per inch)  Used as a measurement of magnetic track density. Standard 5 1/4" 360KB floppy disks have a density of 48TPI, and the 1.2MB disks have a 96TPI density. All 3 1/2" disks have a 135.4667TPI density, and hard disks can have densities greater than 3,000TPI.

track  One of the many concentric circles that holds data on a disk surface. Consists of a single line of magnetic flux changes and is divided into some number of 512-byte sectors.

track density  Expressed as tracks per inch (TPI); defines how many tracks are recorded in 1" of space measured radially from the center of the disk. Sometimes also called radial density.

track-to-track seek time  The time required for read/write heads to move between adjacent tracks.

transistor  A semiconductor device invented in 1947 at Bell Labs (released in 1948) that is used to amplify a signal or open and close a circuit. In digital computers, it functions as an electronic switch. It is reduced to microscopic size in modern digital integrated circuits containing 100 million or more individual transistors.

Transport Layer  In the OSI reference model, when more than one packet is in process at any time, such as when a large file must be split into multiple packets for transmission, this is the layer that controls the sequencing of the message components and regulates inbound traffic flow. See also OSI.

transportable computer  A computer system larger than a portable system and similar in size and shape to a portable sewing machine. Most transportables conform to a design similar to the original Compaq portable, with a built-in CRT display. These systems are characteristically very heavy and run on only AC power. Because of advances primarily in LCD and plasma-display technology, these systems are obsolete and have been replaced by portable systems.

troubleshooting  The task of determining the cause of a problem.

true-color images  Also called 24-bit color images because each pixel is represented by 24 bits of data, allowing for 16.7 million colors. The number of colors possible is based on the number of bits used to represent the color. If 8 bits are used, 256 possible color values ($2^8$) exist. To obtain 16.7 million colors, each of the primary colors (red, green, and blue) is represented by 8 bits per pixel, which enables 256 possible shades for each of the primary red, green, and blue colors or $256 	imes 256 	imes 256 = 16.7$ million total colors.

TrueType  An Apple/Microsoft developed scalable font technology designed to provide a high-performance alternative to PostScript Type 1 fonts. TrueType fonts are supported by both Windows and MacOS, but a particular TrueType font must either be made in both MacOS and Windows versions or support the cross-platform OpenType font format to be used on both platforms.

TSR (terminate-and-stay-resident)  A program that remains in memory after being loaded. Because they remain in memory, TSR programs can be reactivated by a predefined keystroke sequence or other operation while another program is active. Usually called resident programs. TSR programs are often loaded from the AUTOEXEC.BAT file used at startup by DOS and Windows 9x.

TTL (transistor-to-transistor logic)  Digital signals often are called TTL signals. A TTL display is a monitor that accepts digital input at standardized signal voltage levels.

TWAIN  Imaging standard used to interface scanners and digital cameras to applications such as Photoshop and other image editors. TWAIN enables the user to scan or download pictures without exiting the image editing program.

TweakUI  An unsupported software utility provided by Microsoft for 32-bit Windows users. TweakUI allows users to change the user interface and adjust Registry settings without manual Registry editing.

twisted pair  A type of wire in which two small, insulated copper wires are wrapped or twisted around each other to minimize interference from other wires in the cable. Two types of twisted-pair cables are available: unshielded and shielded. Unshielded twisted-pair (UTP) wiring commonly is used in telephone cables and 10BASE-T, 100BASE-TX, and 1000BASE-T networking and provides little protection against interference. Shielded twisted-pair (STP) wiring is used in some networks or any application in which immunity from electrical interference is more important. Twisted-pair wire is much easier to work with than coaxial cable and is cheaper as well.
**typematic** The keyboard repeatedly sending the keypress code to the motherboard for a key that is held down. The delay before the code begins to repeat and the speed at which it repeats are user adjustable through `MODE` commands in DOS or the Windows Control Panel.

**UART (Universal Asynchronous Receiver Transmitter)** A chip device that controls the RS-232 serial port in a PC-compatible system. Originally developed by National Semiconductor, several UART versions are in PC-compatible systems: The 8250B is used in PC- and XT-class systems, and the 16450 and 16650 series are used in AT-class systems. The 16650 and higher UARTs are used for specialized high-speed serial communication cards.

**UDF (Universal Disk Format)** The disk format used by packet-writing software, such as Adaptec DirectCD. See also *Mt. Rainier* and *packet writing*.

**Ultra DMA (UDMA or Ultra ATA)** A protocol for transferring data to an ATA interface hard drive. The Ultra DMA/33 protocol transfers data in burst mode at a rate of 33MBps, whereas the even faster Ultra DMA/66 protocol transfers at 66MBps. Ultra DMA/66 also requires the use of a special 80-conductor cable for signal integrity. This cable also is recommended for Ultra DMA/33 and is backward compatible with standard ATA/IDE cables. The fastest UDMA modes are Ultra DMA/100 (supported by most recent chipsets) and Ultra DMA/133 (introduced by Maxtor in 2001).

**UltraXGA (UXGA)** A screen resolution of 600×1200.

**UMB (upper memory block)** A block of unused memory in the upper memory area (UMA), which is the 384KB region between 640KB and 1MB of memory space in the PC. BIOS chips and memory buffers on add-on cards must be configured to use empty areas of the UMB; otherwise, they will not work.

**unformatted capacity** The total number of bytes of data that can fit on a disk. The formatted capacity is lower because space is lost defining the boundaries between sectors. For example, some vendors have referred to the high-density 1.44MB floppy disk as a 2.0MB disk (2.0MB is the unformatted capacity). However, because most media is preformatted today, this issue is fading away.

**Unicode** A worldwide standard for displaying, interchanging, and processing all types of language texts, including both those based on letters (such as Western European languages) and pictographs (such as Chinese, Japanese, and Korean).

**uninterruptible power supply (UPS)** A device that supplies power to the computer from batteries so power will not stop, even momentarily, during a power outage. The batteries are recharged constantly from a wall socket.

**Universal Asynchronous Receiver Transmitter** See *UART*.

**unzipping** The process of extracting one or more files from a PKZIP or WinZip-compatible archive file.

**UPC (universal product code)** A 10-digit computer-readable bar code used in labeling retail products. The code in the form of vertical bars includes a five-digit manufacturer identification number and a five-digit product code number.

**update** To modify information already contained in a file or program with current information.

**upper memory area (UMA)** The 384KB of memory between 640KB and 1MB. See also UMB.

**URL (uniform resource locator)** The primary naming scheme used to identify a particular site or file on the World Wide Web. URLs combine information about the protocol being used, the address of the site where the resource is located, the subdirectory location at the site, and the name of the particular file (or page) in question.

**USB (universal serial bus)** USB version 1.1 is a 12Mbps (1.5MBps) interface over a simple four-wire connection. The bus supports up to 127 devices and uses a tiered star topology built on expansion hubs that can reside in the PC, any USB peripheral, or even standalone hub boxes. USB 2.0, also called High-Speed USB, runs at 480Mbps and handles multiple devices better than USB 1.1.

**utility** A program that carries out routine procedures to make computer use easier.

**UTP (unshielded twisted pair)** A type of wire often used indoors to connect telephones or computer devices. Comes with two or four wires twisted inside a flexible plastic sheath or conduit and uses modular plugs and phone jacks.

**V.21** An ITU standard for modem communications at 300bps. Modems made in the U.S. or Canada follow the Bell 103 standard but can be set to answer V.21 calls from overseas. The actual transmission rate is 300 baud and employs frequency shift keying (FSK) modulation, which encodes a single bit per baud.

**V.22** An ITU standard for modem communications at 1,200bps, with an optional fallback to 600bps. V.22 is partially compatible with the Bell 212A standard observed in the U.S. and Canada. The actual transmission rate is 600 baud, using differential-phase shift keying (DPSK) to encode as much as 2 bits per baud.

**V.22bis** An ITU standard for modem communications at 2,400bps. Includes an automatic link-negotiation fallback to 1,200bps and compatibility with Bell 212A/V.22 modems. The actual transmission rate is 600 baud, using quadrature amplitude modulation (QAM) to encode as much as 4 bits per baud.
Appendix A  

V.23  An ITU standard for modem communications at 1,200bps or 600bps with a 75bps back channel. Used in the United Kingdom for some videotext systems.

V.25  An ITU standard for modem communications that specifies an answer tone different from the Bell answer tone used in the U.S. and Canada. Most intelligent modems can be set with an ATB0 command so they use the V.25 2,100Hz tone when answering overseas calls.

V.32  An ITU standard for modem communications at 9,600bps and 4,800bps. V.32 modems fall back to 4,800bps when line quality is impaired and fall forward again to 9,600bps when line quality improves. The actual transmission rate is 2,400 baud using quadrature amplitude modulation (QAM) and optional trellis-coded modulation (TCM) to encode as much as 4 data bits per baud.

V.32bis  An ITU standard that extends the standard V.32 connection range and supports 4,800bps; 7,200bps; 9,600bps; 12,000bps; and 14,400bps transmission rates. V.32bis modems fall back to the next lower speed when line quality is impaired, fall back further as necessary, and fall forward to the next higher speed when line quality improves. The actual transmission rate is 2,400 baud using quadrature amplitude modulation (QAM) and trellis-coded modulation (TCM) to encode as much as 6 data bits per baud.

V.32terbo  A proprietary standard proposed by several modem manufacturers that will be cheaper to implement than the standard V.32 fast protocol but that will support transmission speeds of up to only 18,800bps. Because it is not an industry standard, it is not likely to have widespread industry support.

V.34  An ITU standard that extends the standard V.32bis connection range, supporting 28,800bps transmission rates as well as all the functions and rates of V.32bis. This was called V.32fast or V.fast while under development.

V.34+  An ITU standard that extends the standard V.34 connection range, supporting 33,600bps transmission rates as well as all the functions and rates of V.34.

V.42  An ITU standard for modem communications that defines a two-stage process of detection and negotiation for LAPM error control. Also supports MNP error-control protocol, Levels 1–4.

V.42bis  An extension of CCITT V.42 that defines a specific data-compression scheme for use with V.42 and MNP error control.

V.44  ITU-T designation for a faster data-compression scheme than V.42bis. V.44 can compress data up to 6:1. V.44 is included on most V.92-compliant modems. See also V.92.

V.90  ITU-T designation for defining the standard for 56Kbps communication. Supersedes the proprietary X2 schemes from U.S. Robotics (3Com) and K56flex from Rockwell.

V.92  ITU-T designation for an improved version of the V.90 protocol. V.92 allows faster uploading (up to 48Kbps), faster connections, and optional modem-on-hold (enabling you to take calls while online). Most V.92 modems also support V.44 compression. See also V.44.

V-Link  A VIA Technologies high-speed (266MBps) bus between the North Bridge and South Bridge chips in VIA chipsets, such as the P4X266 (for Pentium 4) and KT266/266A (for Athlon/Duron). V-Link is twice as fast as the PCI bus and provides a dedicated pathway for data transfer.

vaccine  A type of program used to locate and eradicate virus code from infected programs or systems.

corner of a triangle in 3D graphics. The plural of vertex is vertices. See also vertex shader.

vertex shader  A graphics processing function built into recent 3D graphics chips that manipulates vertices by adding color, shading, and texture effects. Recent GPUs such as the NVIDIA GeForce 3 and GeForce Ti and the ATI Radeon series incorporate vertex shaders. See also GPU, hardware shader, and pixel shader.

vertical blanking interval (VBI)  The top and bottom lines in the video field, in which frame numbers, picture stops, chapter stops, white flags, closed captions, and more can be encoded. These lines do not appear on the display screen but maintain image stability and enhance image access.

vertical scan frequency  The rate at which the electron gun in a monitor scans or refreshes the entire screen each second.

very large scale integration  See IC.
VESAs (Video Electronics Standards Association) Founded in the late 1980s by NEC, Home Electronics and eight other leading video board manufacturers with the main goal to standardize the electrical, timing, and programming issues surrounding 800×600 resolution video displays, commonly known as Super VGA. VESA has also developed the Video Local Bus (VL-Bus) standard for connecting high-speed adapters directly to the local processor bus. The most recent VESA standards involve digital flat-panel displays and display identification.

VFAT (virtual file allocation table) A file system used in Windows for Workgroups and Windows 9x. VFAT provides 32-bit protected mode access for file manipulation and supports long filenames (LFNs)—up to 255 characters in Windows 95 and later. VFAT can also read disks prepared with the standard DOS 16-bit FAT. VFAT was called 32-bit file access in Windows for Workgroups. VFAT is not the same as FAT32.

VGA (video graphics array) A type of PC video display circuit (and adapter) first introduced by IBM on April 2, 1987, which supports text and graphics. Text is supported at a maximum resolution of 80×25 characters in 16 colors with a character box of 9×16 pixels. Graphics are supported at a maximum resolution of 320×200 pixels in 256 (from a palette of 262,144) colors or 640×480 pixels in 16 colors. The VGA outputs an analog signal with a horizontal scanning frequency of 31.5kHz and supports analog color or analog monochrome displays. Also refers generically to any adapter or display capable of 640×480 resolution.

VHS (Video Home System) A popular consumer videotape format developed by Matsushita and JVC.

VIA Technologies A popular vendor of chipsets for AMD Athlon and Intel Pentium 4–based systems; it’s also the maker of the VIA C3 processor.

video A system of recording and transmitting primarily visual information by translating moving or still images into electrical signals. The term video properly refers to only the picture, but as a generic term, video usually embraces audio and other signals that are part of a complete program. Video now includes not only broadcast television but many nonbroadcast applications, such as corporate communications, marketing, home entertainment, games, teletext, security, and even the visual display units of computer-based technology.

Video 8 or 8mm Video Video format based on the 8mm videotapes popularized by Sony for camcorders.

video adapter An expansion card or chipset built into a motherboard that provides the capability to display text and graphics onscreen. If the adapter is part of an expansion card, it also includes the physical connector for the monitor cable. If the chipset is on the motherboard, the video connector is on the motherboard as well.

video graphics array See VGA.

video-on-CD or video CD A full-motion digital video format using MPEG video compression and incorporating a variety of VCR-like control capabilities. See also White Book.

virtual disk A RAM disk or “phantom disk drive” in which a section of system memory (usually RAM) is set aside to hold data, just as though it were several disk sectors. To DOS, a virtual disk looks and functions like any other “real” drive.

virtual memory A technique by which operating systems such as 32-bit Windows versions load more programs and data into memory than they can hold. Parts of the programs and data are kept on disk and constantly swapped back and forth into system memory. The applications’ software programs are unaware of this setup and act as though a large amount of memory is available.

virtual real mode A mode available in all Intel 80386-compatible processors. In this mode, memory addressing is limited to 4,096MB, restricted protection levels can be set to trap software crashes and control the system, and individual real-mode compatible sessions can be set up and maintained separately from one another.

virus A type of resident program designed to replicate itself. Usually at some later time when the virus is running, it causes an undesirable action to take place.

VL-Bus (VESA Local Bus) A standard 32-bit expansion slot bus specification used in 486 PCs, the VL-Bus connector was an extension of the ISA slot; any VL-Bus slot is also an ISA slot. Replaced by the PCI bus, the VL-Bus slot was used on only a very few early Pentium systems.

VMM (Virtual Memory Manager) A facility in Windows enhanced mode that manages the task of swapping data in and out of 386 and later processor virtual real-mode memory space for multiple non-Windows applications running in virtual real mode.

voice-coil actuator A device that moves read/write heads across hard disk platters by magnetic interaction between coils of wire and a magnet. Functions somewhat like an audio speaker, from which the name originated. The standard actuator type on hard drives.

volatile memory Memory that does not hold data without power. Both Dynamic RAM (the main RAM in a computer) and Static RAM (used for cache memory) are considered volatile memory. See also nonvolatile memory.

voltage reduction technology An Intel processor technology that enables a processor to draw the standard voltage from the motherboard but run the internal processor core at a lower voltage.
**voltage regulator** A device that smoothes out voltage irregularities in the power fed to the computer.

**volume** A portion of a disk signified by a single drive specifier. Under DOS v3.3 and later, a single hard disk can be partitioned into several volumes, each with its own logical drive specifier (C:, D:, E:, and so on).

**volume label** An identifier or name of up to 11 characters that names a disk.

**VPN (virtual private network)** A private network operated within a public network. To maintain privacy, VPNs use access control and encryption.

**VRAM (video random-access memory)** VRAM chips are modified DRAMs on video boards that enable simultaneous access by the host system’s processor and the processor on the video board. A large amount of information therefore can be transferred quickly between the video board and system processor. Sometimes also called dual-ported RAM. It has been replaced by SDRAM, SGRAM, and DDR SDRAM on recent high-performance video cards.

**VxD (virtual device driver)** A special type of Windows driver. VxDs run at the most privileged CPU mode (ring 0) and enable low-level interaction with Windows driver. VxDs require none of these cycles because of the use of L1 cache

**wafer** A thin, circular piece of silicon either 8'' (200mm) or 12'' (300mm) in diameter from which processors, memory, and other semiconductor electronics are manufactured.

**wait states** One or more pause cycles added during certain system operations that require the processor to wait until memory or some other system component can respond. Adding wait states enables a high-speed processor to synchronize with lower-cost, slower components. A system that runs with “zero wait states” requires none of these cycles because of the use of faster memory or other components in the system. The widespread use of L1 and L2 memory caches has made the issue of wait states largely irrelevant. See also L1 cache and L2 cache.

**warm boot** Rebooting a system by means of a software command rather than turning the power off and back on. See also cold boot.

**wave table synthesis** A method of creating synthetic sound on a sound card that uses actual musical instrument sounds sampled and stored on ROM (or RAM) on the sound card or in system RAM. The sound card then modifies this sample to create any note necessary for that instrument. Produces much better sound quality than FM synthesis.

**Webcam** An inexpensive (usually under $100) video camera that plugs into a USB or an IEEE-1394/FireWire port for use with video chat, Web sites, or email programs.

**Whetstone** A benchmark program developed in 1976 and designed to simulate arithmetic-intensive programs used in scientific computing. Remains completely CPU-bound and performs no I/O or system calls. Originally written in ALGOL, although the C and Pascal versions became more popular by the late 1980s. The speed at which a system performs floating-point operations often is measured in units of Whetstones.

**Whitney technology** A term referring to a magnetic disk design that usually has oxide or thin film media, thin film read/write heads, low floating-height sliders, and low-mass actuator arms that together allow higher bit densities than the older Winchester technology. Whitney technology first was introduced with the IBM 3370 disk drive, circa 1979.

**Wi-Fi** Name for IEEE 802.11b–compliant network hardware that also meets the interoperability standards of the Wireless Ethernet Compatibility Alliance (WECA). Despite the presence of Wi-Fi approval for various brands of hardware, achieving the simplest setup and operation is still easier if you purchase Wi-Fi/802.11b wireless NICs and access points from the same vendor. See also 802.11.

**wide area network (WAN)** A LAN that extends beyond the boundaries of a single building.

**Winchester drive** Any ordinary, nonremovable (or fixed) hard disk drive. The name originates from a particular IBM drive in the 1960s that had 30MB of fixed and 30MB of removable storage. This 30-30 drive matched the caliber figure for a popular series of rifles made by Winchester, so the slang term *Winchester* was applied to any fixed-platter hard disk.

**Winchester technology** The term Winchester is loosely applied to mean any disk with a fixed or nonremovable recording medium. More precisely, the term applies to a ferrite read/write head and slider design with oxide media that was first employed in the IBM 3340 disk drive, circa 1973. Virtually all drives today actually use developments of Whitney technology.

**Wintel** The common name given to computers running Microsoft Windows using Intel (or compatible) processors. A slang term for the PC standard.

**wire frames** The most common technique used to construct a 3D object for animation. A wire frame is given coordinates of length, height, and width. Wire frames are then filled with textures, colors, and movement. Transforming a wire frame into a textured object is called rendering.
**word length**  The number of bits in a data character without parity, start, or stop bits.

**workstation**  1) A somewhat vague term describing any high-performance, single-user computer that usually has been adapted for specialized graphics, computer-aided design, computer-aided engineering, or scientific applications. 2) A computer connected to a server.

**World Wide Web (WWW)**  Also called the Web. A graphical information system based on hypertext that enables a user to easily access documents located on the Internet.

**WORM (write-once, read-many or multiple)**  An optical mass-storage device capable of storing many megabytes of information but that can be written to only once on any given area of the disk. A WORM disk typically holds more than 200MB of data. Because a WORM drive can’t write over an old version of a file, new copies of files are made and stored on other parts of the disk whenever a file is revised. WORM disks are used to store information when a history of older versions must be maintained. Recording on a WORM disk is performed by a laser writer that burns pits in a thin metallic film (usually tellurium) embedded in the disk. This burning process is called ablation. WORM drives are frequently used for archiving data. WORM drives have been replaced by CD-R drives, which have a capacity of 650MB–700MB but have similar characteristics.

**write precompensation**  A modification applied to write data by a controller to partially alleviate the problem of bit shift, which causes adjacent 1s written on magnetic media to read as though they were farther apart. When adjacent 1s are sensed by the controller, precompensation is used to write them more closely together on the disk, thus enabling them to be read in the proper bit cell window. Drives with built-in controllers typically handle precompensation automatically. Precompensation usually is required for the inner cylinders of now-obsolete oxide media drives.

**write protect**  Preventing a removable disk or Sony Memory Stick from being overwritten by means of covering a notch or repositioning a sliding switch, depending on the type of media.

**X2**  A proprietary modem standard developed by U.S. Robotics (since acquired by 3Com) that enables modems to receive data at up to 56Kbps. This has been superseded by the V.90 standard. See also V.90 and V.92.

**x86**  A generic term referring to Intel and Intel-compatible PC microprocessors. Although the Pentium family processors do not have a numeric designation because of trademark law limitations on trademarking numbers, they are later generations of this family.

**Xeon**  Intel’s family name for its server processors derived from the Pentium II, Pentium III, and Pentium 4 desktop processors. The Pentium II Xeon and Pentium III Xeon use Slot 2, whereas Xeon (the Pentium 4 version does not have a numerical designation) uses the new Socket 602. All Xeon processors have larger caches and memory addressing schemes than their desktop counterparts.

**XGA (extended graphics array)**  A type of PC video display circuit (and adapter) first introduced by IBM on October 30, 1990, that supports text and graphics. Text is supported at a maximum resolution of 132×60 characters in 16 colors with a character box of 8×6 pixels. Graphics are supported at a maximum resolution of 1024×768 pixels in 256 (from a palette of 262,144) colors or 640×480 pixels in 65,536 colors. The XGA outputs an analog signal with a horizontal scanning frequency of 31.5KHz or 35.52KHz and supports analog color or analog monochrome displays. Also used to refer generically to any adapter or display capable of 1024×768 resolution.

**XML (Extensible Markup Language)**  A standard for creating and sharing data and data formats over the Internet and other networks. XML, like HTML, uses markup tags to control the page, but XML tags control both appearance and the uses of the data and can be extended with new tags created by any XML user. See also W3C.

**XMM (extended memory manager)**  A driver that controls access to extended memory on 286 and later processor systems. HIMEM.SYS is an example of an XMM that comes with DOS and Windows 9x.

**XModem**  A file-transfer protocol—with error checking—developed by Ward Christensen in the mid-1970s and placed in the public domain. Designed to transfer files between machines running the CP/M operating system and using 300bps or 1,200bps modems. Until the late 1980s, because of its simplicity and public-domain status, XModem remained the most widely used microcomputer file-transfer protocol. In standard XModem, the transmitted blocks are 128 bytes. 1KB-XModem is an extension to XModem that increases the block size to 1,024 bytes. Many newer file-transfer protocols that are much faster and more accurate than XModem have been developed, such as YModem and ZModem.

**XMS (extended memory specification)**  A Microsoft-developed standard that provides a way for real-mode applications to access extended memory in a controlled fashion. The XMS standard is available from Microsoft.

**XON/XOFF**  Standard ASCII control characters used to tell an intelligent device to stop or resume transmitting data. In most systems, pressing Ctrl+S sends the XOFF character. Most devices understand Ctrl+Q as XON; others interpret the pressing of any key after Ctrl+S as XON.
Y-connector  A Y-shaped splitter cable that divides a source input into two output signals.

Y-mouse  A family of adapters from P.I. Engineering that enables a single mouse port to drive two devices. P.I. Engineering also makes the Y-see adapter for dual monitors and the Y-key adapter for dual keyboards.

Yellow Book  The standard used by CD-ROM. Multimedia applications most commonly use the Yellow Book standard, which specifies how digital information is to be stored on the CD-ROM and read by a computer. Extended architecture (XA) is currently an extension of the Yellow Book that enables the combination of various data types (audio and video, for example) onto one track in a CD-ROM. Without XA, a CD-ROM can access only one data type at a time. Many CD-ROM drives are now XA capable.

Yellow Book standards  See CD-ROM.

YModem  A file-transfer protocol first released as part of Chuck Forsberg's YAM (yet another modem) program. An extension to XModem designed to overcome some of the limitations of the original. Enables information about the transmitted file, such as the filename and length, to be sent along with the file data and increases the size of a block from 128 bytes to 1,024 bytes. YModem-batch adds the capability to transmit batches, or groups, of files without operator interruption. YModemG is a variation that sends the entire file before waiting for an acknowledgment. If the receiving side detects an error midstream, the transfer is aborted. YModemG is designed for use with modems that have built-in error-correcting capabilities.

Z-buffering  A 3D graphics technique used to determine which objects in a 3D scene will be visible to the user and which will be blocked by other objects. Z-buffering displays only the visible pixels in each object.

Zero wait states  See wait states.

ZIF (zero insertion force)  Sockets that require no force for the insertion of a chip carrier. Usually accomplished through movable contacts, ZIF sockets are used by 486, Pentium, Pentium Pro, and other socketed processors (including the latest Pentium 4 and AMD Athlon and Duron models).

ZIP (zigzag inline package)  A DIP package that has all leads on one edge in a zigzag pattern and mounts in a vertical plane.

Zip drive  An external drive manufactured by Iomega that supports 100MB or 250MB magnetic media on a 3 1/2" removable drive.

Zip file  A file created using PKZIP, WinZip, or a compatible archiving program.

Zipping  The process of creating a PKZIP or WinZip-compatible archive file. See also unzipping.

ZModem  A file-transfer protocol commissioned by Telenet and placed in the public domain. Like YModem, it was designed by Chuck Forsberg and developed as an extension to XModem to overcome the inherent latency when using Send/Ack-based protocols, such as XModem and YModem. It is a streaming, sliding-window protocol.

Zoned recording  In hard drives, one way to increase the capacity of a hard drive is to format more sectors on the outer cylinders than on the inner ones. Zoned recording splits the cylinders into groups called zones, with each successive zone having more and more sectors per track, moving out from the inner radius of the disk. All the cylinders in a particular zone have the same number of sectors per track.

Zoomed video  A direct video bus connection between the PC-Card adapter and a mobile system's VGA controller, enabling high-speed video displays for videoconferencing applications and MPEG decoders.
Key Vendor Contact Information

Use this vendor quick reference chart to locate primary contact information for vendors mentioned in this book. Be sure to refer to the vendor database included on the DVD accompanying this book. This database contains detailed contact information and descriptions of services and is keyword searchable.

Troubleshooting Index

This special index is designed to help you find solutions to problems—fast. Whether your system is beeping at startup, you're getting the dreaded blue screen of death, or you can't hear your rocket launcher blasts in your latest Unreal Tournament Deathmatch, this index will help you find solutions, quickly and relatively painlessly.

## Troubleshooting Index

<table>
<thead>
<tr>
<th>Technology</th>
<th>Symptom</th>
<th>Cause</th>
<th>Solution</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floppy drive</td>
<td>File copying error after copying a few files with long filenames to the floppy disk.</td>
<td>Root directory fills up due to use of multiple directory entries by each long filename.</td>
<td>Create a folder on the floppy disk and copy files with long filenames into the folder.</td>
<td>1327</td>
</tr>
<tr>
<td>Floppy drive</td>
<td>Disk access light stays on continuously after system is started.</td>
<td>One end of floppy cable is reversed.</td>
<td>Change reversed end of floppy cable, verifying pin 1 to pin 1.</td>
<td>833</td>
</tr>
<tr>
<td>Hard disk</td>
<td>Can’t access full capacity of hard drive over 8.4GB.</td>
<td>BIOS is out-of-date.</td>
<td>Upgrade Flash BIOS.</td>
<td>384</td>
</tr>
<tr>
<td>Hard disk</td>
<td>Can’t access full capacity of hard drive over 8.4GB.</td>
<td>BIOS is out-of-date, and BIOS upgrade is not available.</td>
<td>Install an add-on BIOS card with EDD support.</td>
<td>530</td>
</tr>
<tr>
<td>Hard disk</td>
<td>Can’t use UDMA drives at full speed.</td>
<td>BIOS is out-of-date.</td>
<td>Upgrade Flash BIOS.</td>
<td>384</td>
</tr>
<tr>
<td>Hard disk</td>
<td>IDE drive not ready errors during startup.</td>
<td>Drive not spinning up fast enough at startup.</td>
<td>Enable or increase hard disk predelay time.</td>
<td>402</td>
</tr>
<tr>
<td>Hard disk</td>
<td>Can’t use drive capacity beyond 528MB.</td>
<td>LBA mode not enabled in BIOS.</td>
<td>Enable LBA mode.</td>
<td>402</td>
</tr>
<tr>
<td>Hard disk</td>
<td>Storing small file uses up a large amount of space on drive.</td>
<td>Files smaller than an allocation unit (cluster) still use an entire allocation unit.</td>
<td>Convert drive to FAT32 or NTFS to be more efficient if possible; remove outdated files from system to save space.</td>
<td>1326</td>
</tr>
<tr>
<td>Hard disk</td>
<td>Your 40GB hard disk can’t be formatted by Windows 2000 or Windows XP as a single drive with FAT32.</td>
<td>These versions can format up to 32GB only, but can read larger drives.</td>
<td>Prepare drive with third-party utility such as PartitionMagic or use NTFS.</td>
<td>1303</td>
</tr>
<tr>
<td>Hard disk</td>
<td>Large numbers of files ending in .CHK are found in root directory of drive.</td>
<td>.CHK files are created by SCANDISK or CHKDSK from lost allocation units.</td>
<td>Shut down system properly to avoid lost allocation units; test drive if problem persists; delete files to free up space.</td>
<td>1335</td>
</tr>
<tr>
<td>Hard drive</td>
<td>UDMA/66 or UDMA/100 drive runs at UDMA/33 on systems that support UDMA/66 or UDMA/100.</td>
<td>Incorrect cable might be in use.</td>
<td>Use 80-wire UDMA cable in place of normal 40-wire IDE cable.</td>
<td>506</td>
</tr>
<tr>
<td>Hard drive</td>
<td>System won’t boot after installing new IDE drive.</td>
<td>Cable might be reversed.</td>
<td>Make sure pin 1 on both ends of cable is connected to interfaces’ pin 1.</td>
<td>508</td>
</tr>
<tr>
<td>Hard drive</td>
<td>Can’t set IDE drives as master or slave when 80-wire cable is used.</td>
<td>80-wire cable supports cable select, not master/slave.</td>
<td>Install drives at correct locations on cable, and jumper both as Cable Select.</td>
<td>506</td>
</tr>
<tr>
<td>Hard drive</td>
<td>Can’t read contents of IDE drive over 528MB after moving it to a new system.</td>
<td>Drive geometry or translation not set correctly on new system.</td>
<td>Set correct Cyl-Hd-Sectors setting for drive and LBA or Ext CHS translation.</td>
<td>517</td>
</tr>
<tr>
<td>Hard drive</td>
<td>BIOS recognizes full capacity of drive over 8.4GB, but operating system will not.</td>
<td>Some operating systems aren’t designed to use drives over 8.4GB.</td>
<td>Upgrade or patch your operating system to achieve compliance.</td>
<td>530</td>
</tr>

<td>------</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Can’t read CD-R or CD-RW disc on a CD-ROM drive, but only on a CD-R/CD-RW drive.</td>
<td>CD probably was created with packet-writing software and not closed before being removed.</td>
<td>Return CD-R or CD-RW disc to original system and close session.</td>
<td>730</td>
</tr>
<tr>
<td>Optical drives</td>
<td>CD-ROM disc can be read by 32-bit Windows but not by DOS.</td>
<td>CD was created using the UDF (packet-writing) standard.</td>
<td>Use standard mastering software instead of DirectCD to create CDs for use with DOS.</td>
<td>738</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Drive runs very slowly or has read errors.</td>
<td>CD lens might be dirty or dusty.</td>
<td>Use a CD lens cleaner, or install a drive with a self-cleaning lens.</td>
<td>758, 790</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Can’t read CD-RW media on an older drive.</td>
<td>Drives that aren’t MultiRead compliant can’t read CD-RW media (usually slower than 24x speed).</td>
<td>Replace drive with a MultiRead-compatible CD-ROM or DVD drive or a CD-RW drive.</td>
<td>766</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Can’t read CD-RW media on MultiRead CD-ROM drive.</td>
<td>Compatible UDF reader might not be installed.</td>
<td>Install UDF reader from CD-RW disc or by downloading reader from software vendor.</td>
<td>790</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Can’t write to a 10x or faster CD-RW disc in a 4x CD-RW drive.</td>
<td>10x and faster media meets the High-Speed or Ultra-Speed Rewritable standard; not supported by 2x and 4x CD-RW drives.</td>
<td>Use 2x or 4x media for interchange between 10x or faster and 2x/4x CD-RW drives.</td>
<td>766</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Can’t write to CD-RW or DVD-RW 1x media.</td>
<td>Media might not be formatted.</td>
<td>Format media with UDF packet-writing software before use.</td>
<td>792</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Can’t write to CD-RW or DVD-RW 1x media.</td>
<td>Media formatted with different UDF program.</td>
<td>Use same UDF packet-writing software to format media and write to media.</td>
<td>792</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Can’t write to CD-RW or DVD-RW 1x media.</td>
<td>Media might not be correctly identified.</td>
<td>Eject and reinsert media to force redetection.</td>
<td>792</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Can’t write to CD-RW or DVD-RW 1x media.</td>
<td>UDF packet-writing software might not support drive.</td>
<td>Contact software vendor for an update.</td>
<td>792</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Can’t write to CD-RW or DVD-RW 1x media.</td>
<td>Disc might have been formatted with Windows XP’s own CD-writing software.</td>
<td>Erase media with Windows XP’s CD-writing software and reformat with preferred UDF solution.</td>
<td>792</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Can’t write to CD-RW or DVD-RW 1x media.</td>
<td>Drive firmware might be out-of-date.</td>
<td>Update firmware.</td>
<td>793</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Can’t read CD-RW media on a CD-ROM drive.</td>
<td>Media might be damaged.</td>
<td>Reinstall media in original drive; repair media if necessary with UDF packet-writing software utilities.</td>
<td>793</td>
</tr>
<tr>
<td>Optical drives</td>
<td>CD-RW or rewritable DVD drive writes to some types of media more slowly than others.</td>
<td>Drive firmware might not be fully compatible with media type in use.</td>
<td>Download and install the latest firmware for the drive.</td>
<td>793</td>
</tr>
<tr>
<td>Optical drives</td>
<td>DVD-RW drive is not compatible with 4x DVD-RW media.</td>
<td>Drive firmware was designed before 4x media was introduced.</td>
<td>Download and install the latest firmware for drive and use only 2x media until update is installed.</td>
<td>793</td>
</tr>
<tr>
<td>Optical drives</td>
<td>Cannot install new drive firmware.</td>
<td>Drive is being controlled by other software.</td>
<td>Disable CD-writing software before performing firmware update.</td>

API (application programming interface)
APIC (advanced programmable interrupt controller)
APM (Advanced Power Management)
APS (analogue protection system)
ARLL (advanced run length limited)
ASPI (Advanced SCSI Programming Interface)
AT (Advanced Technology)
ATA (AT Attachment)
ATAPI (AT Attachment Packet Interface)
ATF (auto tracking following)
AWG (American Wire Gauge)

B

BASIC (beginner's all-purpose symbolic instruction code)
BBSs (bulletin board systems)
BBUL (bumpless build-up layer)
BEDO RAM (burst extended data out RAM)
BF (bus frequency)

BiCMOS (bipolar complementary metal-oxide semiconductor)
BIOS (basic input/output system)
BLER (block error rate)
BOOTP (bootstrap protocol)
BRI (basic rate interface)
BSOD (blue screen of death)
BTB (branch target buffer)
BURN-Proof (Buffer Under-Run error Proof)

C

CAB (cabinet file)
CAM (common access method)
CAM ATA (Common Access Method AT Attachment)
CAP (carrierless amplitude/phase)
CAS (column address strobe)
CAT (category)
CATV (community access television)
CCITT (Comite Consultatif International Telephonique et Telegraphique)
CD (compact disc)
CD-DA (compact disc digital audio)
CD-MO (compact disc magneto-optical)
CD-R (compact disc-recordable)
CD-ROM (compact disc read-only memory)
CD-RW (compact disc-rewritable)
CDMA (code-division multiple access)
CDSL (consumer DSL)
CERN (Conseil Européen pour la Recherche Nucléaire, or European Organisation for Nuclear Research)
CF (compact flash)
CFCs (chlorofluorocarbons)
CGA (color graphics adapter)
CHAP (Challenge-Handshake Authentication Protocol)
CHS (cylinder head sector)
CIRC (cross-interleave Reed-Solomon code)
CISC (complex instruction set computer)
CLKMUL (clock multiplier)
CLV (constant linear velocity)
CMYK (cyan magenta yellow black)
CNR (Communications and Networking Riser)
COC (chip on ceramic)
CPU (central processing unit)
CRC (cyclical redundancy checking)
CRT (cathode-ray tube)
CS (cable select)
CS (central switch)
CSA (Canadian Standards Agency)
CSEL (cable select)
CSMA/CD (carrier sense multiple access/collision detect)
CSS (contact start stop)
CSS (content scramble system)
CTFT (color thin film transistor)
DAC (digital-to-analog converter)
DAE (digital audio extraction)
DASD (direct access storage device)
DASP (drive action/slave present)
DAT (digital audio tape)
db (decibel)
DBB (dynamic bass boost)
DBR (DOS boot record)
DCC (direct cable connection)
DDMA (Distributed DMA)
DDR SDRAM (double data rate SDRAM)
DDS (digital data storage)
DDWG (Digital Display Working Group)
DFP (digital flat panel)
DFT (drive fitness test)
DIB (dual independent bus)
DIMM (dual inline memory module)
DIN (Deutsches Institut für Normung e.V.)
DIP (dual inline package)
DIVX (Digital Video Express)
DLT (digital linear tape)
DMA (direct memory access)
DMM (digital multimeter)
DMT (discrete multitone)
DOCSIS (data over cable service interface specifications)
DOS (disk operating system)
DPMI (DOS protected mode interface)
DPMS (display power-management signaling)
DRAM (dynamic RAM)
DSK (Dvorak simplified keyboard)
DSL (digital subscriber line)
DSLAM (DSL access multiplier)
DSP (digital signal processor)
DSTN (Double-layer SuperTwist Nematic) LCD
DVD (digital versatile disc)
DVD-R (DVD-recordable)
DVD+RW (DVD phase change rewritable)
DVI (Digital Video Interface)

E
EAX (environmental audio extensions)
ECC (error correction code)
ECP (enhanced capabilities port)
EDD (enhanced disk drive)
EDO RAM (extended data out RAM)
EEPROM (electronically erasable programmable ROM)
EFM (eight to fourteen modulation) data encoding
EFS (encrypted file system)
EGA (enhanced graphics adapter)
EIDE (Enhanced IDE)
EISA (Extended Industry Standard Architecture)
ELF (extremely low frequency)
EMI (electromagnetic interference)
ENIAC (Electrical Numerical Integrator and Calculator)
EPIC (explicitly parallel instruction computing)
EPP (Enhanced Parallel Port)
EPROM (erasable programmable ROM)
ESD (electrostatic discharge)

F
FAP (Fair Access Policy)
FAQ (frequently asked questions)
FAT (file allocation table)
FC-PGA (flip-chip pin grid array)
FCC (Federal Communications Commission)
FDDI (Fiber Distributed Data Interface)
FDIV (floating-point divide)
FIC (flex interconnect cable)
FIFO (first in first out)
FM (Frequency modulation)
FPM DRAM (Fast Page Mode DRAM)
FPT (forced perfect termination)
FPU (floating point unit)
FSB (front-side bus)
FSK (frequency-shift keying)
FST (flat square tube)
FTP (file transfer protocol)
FUD (fear, uncertainty, and doubt)
FWH (Firmware hub)
Acronyms

G
GB (gigabyte)
GHz (gigahertz)
GiB (gigabyte bytes)
GMCH (graphics memory controller hub)
GMR (giant magnetoresistive)
GPA (graphics performance accelerator)

H
HAN (home area network)
HD-ROM (high-density read-only memory)
HDA (head disk assembly)
HDD (hard disk drive)
HDTV (high-definition television)
HER (hard error rate)
HFC (hybrid fiber/coax)
HFS (Hierarchical file system)
HID (Human interface device)
HLF (high-level formatting)
HMA (high memory area)
HP (Hewlett-Packard)
HPFS (High performance file system)
HRTF (Head-related transfer function)
HVD (High voltage differential)
Hz (Hertz)

I
I/O (input/output)
IC (integrated circuit)
ICH (Integrated controller hub)
iCOMP (Intel Comparative Microprocessor Performance)
ICS (Internet Connection Sharing)
IDE (Integrated Drive Electronics)
IEC (International Electrotechnical Commission)
IED (ID error detection)
IEEE (Institute of Electrical and Electronic Engineers)
IMA (Interactive Multimedia Association)
IMAPI (image mastering application program interface)
IML (Initial microcode load)
INCITS (InterNational Committee on Information Technology Standards)
IOS (input/output supervisor)
IP (Internet Protocol)
IPL (initial program load)
IPS (in-plane switching)
IPX (Internet network packet exchange)
IR (infrared)
IrDA (infrared data)
IRQ (interrupt request)
ISA (Industry Standard Architecture)
ISDN (Integrated Services Digital Network)
ISO (International Organization for Standardization)
ISP (Internet service provider)
ITU (International Telecommunication Union)

J–K
JPEG (Joint Photographic Experts Group)
Kb (kilobit) 1,000 bits
KB (kilobyte) 1,000 bytes
KHz (kilohertz)
Kib (kibibit) 1,024 bits
KiB (kibibyte) 1,024 bytes
KVAR (kilovolt-amperes-reactive)
KVM (keyboard, video, mouse)
KW/KVA (working power/apparent power)

L
L1 (Level 1)
L2 (Level 2)
LAN (local area network)
LBA (logical block address)
LCD (liquid crystal display)
LED (light-emitting diode)
LIF (Low Insertion Force)
LIM (Lotus Intel Microsoft)
LLF (low-level formatting)
LPT (line printer)
LTO (Linear tape-open)
LVD (Low voltage differential)

M
MAU (media access unit or media attachment unit)
Mb (megabit) 1,000,000 bits
MB (megabyte) 1,000,000 bytes
MBR (master boot record)
MC (microcartridge)
MCA (MicroChannel Architecture)
MCH (memory controller hub)
MCM (multichip module)
MFM (modified frequency modulation)
MFT (master file table)
MHz (megahertz)
Mib (mebibit) 1,048,576 bits
MiB (mebibyte) 1,048,576 bytes
MIC (Memory in cassette)
MIDI (Musical Instrument Digital Interface)
MMC (MultiMediaCard)
MMU (memory management unit)
MMX (multimedia extensions or matrix math extensions)
MNP (Microcom Network Protocol)
MO (magneto-optical modem (modulator/demodulator)
MOV (metal-oxide varistor)
MPEG (Motion Picture Experts Group)
MPS (Multiprocessor Specification)
MR (Mircloid Research)
MRH-R (memory repeater hub RDRAM-based)
MRH-S (memory repeater hub SDRAM-based)
MS (Microsoft)
MS-DOS (Microsoft disk operating system)
MSAU (multistation access unit)
MTBF (mean time between failures)
MTH (Memory translator hub)
MTTF (Mean time to failure)
MVA (multidomain vertical alignment)

NAS (network attached storage)
NDP (numeric data processor)
NEAT (New Enhanced AT)
NetBEUI (NetBIOS Extended User Interface)
NetBIOS (network basic input/output system)
NIC (network interface card)
NiCd (nickel cadmium)
NiFe (nickel ferrite)
NiMH (nickel metal hydride)
NMI (nonmaskable interrupt)
NRTC (National Rural Telecommunications Cooperative)
NRZ (non-return to zero)
NTFS (New Technology File System)
NTSC (National Television System Committee)
NVRAM (nonvolatile RAM)

OLGA (organic land grid array)
OS (operating system)
OSI (open systems interconnection)
OSO (overscan operation)
OSTA (Optical Storage Technology Association)
OTP (one-time programmable)
OTP (opposite track path)

P
p-Si (low-temperature polysilicon)
PAC (PCI/AGP Controller)
PAC (pin array cartridge)
PAL (phase alternate line)
PARD (periodic and random deviation)
PC-DOS (personal computer disk operating system)
PCA (power calibration area)
PCI (Peripheral Component Interconnect)
PCMCIA (Personal Computer Memory Card International Association)
PDF (portable document format)
PFA (predictive failure analysis)
PFC (power factor correction)
PGA (pin grid array)
PH (PCI controller hub)
PK (parity inner)
PIIX (PCI ISA IDE Xcelerator)
PIO (programmed input/output)
PLCC (plastic leaded chip carrier)
PLGA (plastic land grid array)
PMA (power memory area)
PnP (Plug and Play)
PO (parity outer)
PoP (point of presence)
POP3 (Post Office Protocol 3)
POST (power on self test)
POTS (plain old telephone service)
PPD (parallel presence detect)
PPD file (postscript printer description file)
PPGA (plastic pin grid array)
PPPI (Programmable Peripheral Interface)
PQFP (plastic quad flat pack)
PRI (primary rate interface)
PRML (Partial-Response Maximum-Likelihood)
PROM (programmable ROM)
PSK (phase-shift keying)
PTP (parallel track path)
Q
QAM (quadrature amplitude modulation)
QEGA (quantum extended graphics array)
QFE (quick fix engineering)
QoS (quality of service)

R
RAB (RAID Advisory Board)
RAID (redundant array of independent disks)
RAM (random access memory)
RAMDAC (Random Access Method of Accounting and Control)
RMDAC (RAM digital-to-analog converter)
RBOC (regional Bell operating company)
RDRAM (Rambus DRAM)
RF (radio frequency)
RFI (radio-frequency interference)
RGB (red green blue)
RIAA (Recording Industry Association of America)
RIMM (Rambus inline memory module)
RISC (reduced instruction set computer)
RLL (run length limited)
RNG (random number generator)
ROM (read-only memory)
RPC (regional playback control)
RRIP (Rock Ridge Interchange Protocol)
RTC (real-time clock)
RTC/NVRAM (real-time clock/nonvolatile memory)

S
SACD (super audio compact disc)
SAL (soft adjacent layer)
SASI (Shugart Associates System Interface)
SATA (Serial ATA)
SCAT (Single Chip AT)
SCMS (serial copy management system)
SCSI (small computer system interface)
SD (super density or secure digital)
SDRAM (synchronous DRAM)
SDSL (symmetrical DSL)
SE (single ended)
SEC (single edge contact)
SEC-DED (single-bit error-correction double-bit error detection)
SECC (Sequential Couleur Avec Memoire)
SER (single edge processor)
SER (soft error rate)
SGRAM (synchronous graphics RAM)
SIMM (single inline memory module)
SIPP (single inline pin package)
SiS (Silicon Integrated Systems)
SMART (Self-Monitoring Analysis and Reporting Technology)
SMI (system management interrupt)
SMM (system management mode)
SNR (signal-to-noise ratio)
SPD (serial presence detect)
SPDIF (Sony/Philips Digital Interface)
SPGA (staggered pin grid array)
SPI (SCSI Parallel Interface)
SPS (standby power supply)
SPSYNC (spindle synchronization)
SRAM (static RAM)
SSE (Streaming SIMD Extensions)
STP (shielded twisted pair)
SVGA (Super Video Graphics Array)
SWAP (Shared Wireless Access Protocol)
SXGA (Super Extended Graphics Array)

T
TAD (telephone answering device)
TAO (track-at-once)
TAPI (telephone application programming interface)
TCP (tape carrier packaging)
TCP/IP (Transmission Control Protocol/Internet Protocol)
TDMA (transparent DMA or time-division multiple access)
TFT (thin film transistor)
TIP (Trouble In Paradise)
TLB (translation lookaside buffer)
TPI (tracks per inch)
TSOP (thin small outline package)
TSR (terminate and stay resident)

U
UART (Universal Asynchronous Receiver/Transmitter)
UDF (Universal Disk Format)
UDMA (Ultra-DMA)
UI (user interface)
UL (Underwriters Laboratories)
UMA (unified memory architecture)
Acronyms

Y–Z
Y2K (year 2000)
ZBR (zoned-bit recording)
ZIF (zero insertion force)
ZV (zoomed video)

V
VAFC (VESA Advanced Feature Connector)
VBR (volume boot record)
VESA (Video Electronics Standards Association)
VESA VIP (Video Interface Port)
VFAT (virtual file allocation table)
VFC (video feature connector)
VGA (Video Graphics Array)
VID (voltage identification)
VIS (viewable image size)
VLF (very low frequency)
VLSI (very large scale integration)
VM (virtual machine)
VMC (VESA Media Channel)
VoIP (voice over IP)
VRM (voltage regular module)
VRT (voltage reduction technology)
VxD (virtual device driver)

W–X
W2K (Windows 2000)
WAN (wide area network)
WAP (Wireless Application Protocol)
WBR (wireless broadband router)
WEP (wired equivalent privacy)
Wi-Fi (Wireless Fidelity)
WORM (write once read many)
XA (extended architecture)
XGA (Extended Graphics Array)
XMS (Extended Memory Specification)
Symbols
-5V power sources, 1127-1128
-12V power sources, 1127-1128
.09-micron manufacturing, 79
.13-micron manufacturing, 79-80

Tired of trying to keep pace with an ever-changing hardware market? Wish you knew more about that new processor or chipset that was just released? Want to know what the world’s most renowned PC hardware authority has to say about a new technology?

If you answered “yes” to any of these questions, point your browser to

www.upgradingandrepairingpcs.com

Scott and Que have assembled this Web site to help you stay on top of an aggressive hardware market that can be confusing to the newbie and the hardware expert alike. Here, you'll find

- In-depth analysis of new technologies
- More than 3 hours of Upgrading and Repairing PCs video available in windows media Player format!
- Reviews of key technologies, hardware, and industry trends
- Frequently asked questions from readers just like you
- How-to videos with Scott Mueller
- A way to send your hardware questions directly to Scott
More knowledge from the PC hardware master!

For years, Scott Mueller has brought you the most complete, up-to-date information on PC hardware. Now, he has taken that formula for success and written two new books, covering today’s hottest topics in the manner you’ve grown to know and trust. Plus, a new edition of *Upgrading and Repairing Networks* is available now. Don’t miss the newest books in the *Upgrading and Repairing* line!

**Upgrading and Repairing Laptops**
ISBN: 0-7897-2800-1
1008 pp.
$49.99 USD
Available Fall 2003!

**Upgrading and Repairing Servers**
1408 pp.
$69.99 USD
Coming Spring 2004!

**Upgrading and Repairing Networks, Fourth Edition**
ISBN: 0-7897-2817-6
1312 pp.
$59.99 USD
On shelves now!
# Upgrading and Repairing PCs, 15th Edition

**Scott Mueller**

Thank you for making *Upgrading and Repairing PCs* by Scott Mueller the best-selling PC hardware repair book of all time. Please help us tailor the content of the next edition to best fit your needs by taking a few minutes to answer these questions and returning this self-addressed form. Your opinion counts!

1. Does your job involve upgrading, repairing, building, or troubleshooting PCs on a regular basis?
   - [ ] Yes
   - [ ] No

2. Did you buy this book for personal or professional use?
   - [ ] Professional use
   - [ ] Personal use
   - [ ] Both

3. Have you purchased previous versions of this book?
   - [ ] Yes (list versions) ________________
   - [ ] No

4. If you are new to Scott's *Upgrading and Repairing PCs*, how did you first hear about it?
   - [ ] Friend
   - [ ] Web advertisement (list site) ________________
   - [ ] Colleague
   - [ ] Bookstore (list bookstore) ________________
   - [ ] School
   - [ ] TV (list program) ________________
   - [ ] Other (specify) ________________

5. Where did you buy this book?
   - [ ] Bookstore
   - [ ] Office club
   - [ ] Computer store
   - [ ] Warehouse club
   - [ ] Internet site (name of Web site) ________________
   - [ ] Consumer electronics store
   - [ ] Other __________ site ________________

6. Which of the following certifications have you earned or do you plan to earn in the next 6 months?
   - [ ] A+:
     - [ ] Have
     - [ ] Plan to have
   - [ ] MCSE:
     - [ ] Have
     - [ ] Plan to have
   - [ ] Network+:
     - [ ] Have
     - [ ] Plan to have
   - [ ] Cisco (any)
     - [ ] Have
     - [ ] Plan to have
   - [ ] Other __________
     - [ ] Have
     - [ ] Plan to have

7. What types of processors are in the computers that you currently use, upgrade, repair, build, or troubleshoot?
   - [ ] Intel Pentium 4
   - [ ] Intel Celeron
   - [ ] Intel Pentium III
   - [ ] Intel Pentium II
   - [ ] Intel Pentium M
   - [ ] Pentium MMX
   - [ ] Intel Pentium 4M
   - [ ] Intel Mobile Pentium III
   - [ ] Intel Mobile Pentium II
   - [ ] Intel Itanium 2
   - [ ] Intel Itanium
   - [ ] Intel Xeon
   - [ ] AMD Athlon 64
   - [ ] AMD Athlon XP
   - [ ] AMD Athlon
   - [ ] AMD K6
   - [ ] AMD K6 II
   - [ ] AMD Athlon MP
   - [ ] AMD Athlon
   - [ ] AMD Opteron
   - [ ] Other __________
   - [ ] 6x86MX
   - [ ] Pentium MMX
   - [ ] Pentium 4M
   - [ ] Pentium M
   - [ ] Pentium II
   - [ ] Pentium
   - [ ] itanium
   - [ ] Itanium
   - [ ] Xeon
   - [ ] Athlon
   - [ ] Athlon
   - [ ] K6
   - [ ] K6 II
   - [ ] Athlon MP
   - [ ] Other

8. Which of the following processor architectures do you prefer or recommend in your systems?
   - [ ] Socket 370 (Pentium III)
   - [ ] Socket 423 (Pentium 4)
   - [ ] Socket 478 (Pentium 4)
   - [ ] Socket 603 (Xeon)
   - [ ] Socket A (Socket 462)
   - [ ] Socket 754 (Athlon 64)
   - [ ] No Preference

9. What types of bus slots are in use in the systems you currently use, upgrade, repair, build, or troubleshoot?
   - [ ] AGP
   - [ ] AGP Pro
   - [ ] PCI Express
   - [ ] PCI
   - [ ] VL-Bus
   - [ ] EISA
   - [ ] MCA
   - [ ] 16-bit ISA
   - [ ] 8-bit ISA

10. What types of removable storage media are currently in use in the systems you use, upgrade, repair, build, or troubleshoot?
    - [ ] 1.44M floppy
    - [ ] 2.88M floppy
    - [ ] LS-120/240 SuperDisk
    - [ ] CD-RW
    - [ ] DVD+RW
    - [ ] DVD-RW (combo)
    - [ ] Magnetic Cartridge Media
    - [ ] Flash Memory (Sony Memory Stick, MultiMedia Cards, etc.)
    - [ ] Other __________

11. What type of hard drive interfaces are currently in use in the systems you use, upgrade, repair, build, or troubleshoot?
    - [ ] IDE (ATA-PIO modes)
    - [ ] IDE (ATA/33)
    - [ ] IDE (ATA/66)
    - [ ] IDE (ATA/100)
    - [ ] IDE (ATA/133)
    - [ ] Serial ATA
    - [ ] SCSI (any type)

12. What operating systems are currently in use in the systems you use, upgrade, repair, build, or troubleshoot?
    - [ ] MS/PC DOS 5 or earlier DOS versions
    - [ ] MS/PC DOS 6.x
    - [ ] Windows 95
    - [ ] Windows NT 3.5x
    - [ ] Windows NT 4
    - [ ] Windows 2000 Server
    - [ ] Windows XP Professional
    - [ ] Windows XP Home
    - [ ] Other_________
13. What troubleshooting, diagnostic, or configuration software do you use to upgrade, repair, build, or trouble-shoot PCs?

- PartitionMagic
- PC Doctor
- DisplayMate
- Tufftest
- Disk Manager
- Checkit
- Other

- DriveImage
- SiSoft Sandra
- PC Certify
- QA+
- Windows 98 System
- Information

- Partition Commander
- AMIDag Suite
- PC Technician
- PC Check
- Norton Utilities
- MicroScope

14. Please list the chapter numbers of the three chapters in this book that you found most useful:

- Most useful
- 2nd most useful
- 3rd most useful

15. Please list the chapter numbers of the three chapters in this book that you found least useful:

- Least useful
- 2nd least useful
- 3rd least useful

16. Please list any other upgrading, repairing, troubleshooting, or hardware configuration topics that are not covered in this book that you would like to see covered or that are covered that you would like to see covered in more detail:

17. What other books in the Scott Mueller Library do you plan on purchasing in the next 6 months?

- Upgrading and Repairing Networks, Fourth Edition
- Upgrading and Repairing PCs: Field Guide
- Upgrading and Repairing Laptops
- Upgrading and Repairing PCs, Video Training Course

- Yes
- No

19. If you have visited, what portions of the site do you find most useful or interesting?

- Videos
- Frequently Asked Questions
- Press releases and information about
- Ask Scott
- Monthly Technology Articles
- Scott's books

If you would agree to be contacted for follow-up surveys or questions regarding this book or other Que books, please fill in the following information. Otherwise, you can leave this blank:

License Agreement

By opening this package, you are agreeing to be bound by the following agreement:

You may not copy or redistribute the entire DVD as a whole. Copying and redistribution of individual software programs on the DVD is governed by terms set by individual copyright holders.

The installer and code from the author(s) are copyrighted by the publisher and the author(s). Individual programs and other items on the DVD are copyrighted or are under GNU license by their various authors or other copyright holders.

This software is sold as is without warranty of any kind, either expressed or implied, including but not limited to the implied warranties of merchantability and fitness for a particular purpose. Neither the publisher nor its dealers or distributors assumes any liability for any alleged or actual damages arising from the use of this program. (Some states do not allow for the exclusion of implied warranties, so the exclusion may not apply to you.)
Installing the DVD

The DVD accompanying this book is playable on both a standalone DVD player (DVD player attached to your television/home theater system) and a DVD drive installed in or connected to your PC.

Standalone DVD Video Players

To play the videos on this DVD, insert the DVD into your standalone DVD video player and navigate the menus using your DVD player’s remote, just as you would do with any DVD.

Note

The DVD is region-free. The extra features using Internet (Web) links are not active links; you must enter the specified URLs into your Web browser directly. Extra features and Windows Media Player–formatted videos are also available on Scott's Web site at www.upgradingandrepairingpcs.com.

PC-Based DVD Drives

To play the DVD video content, do the following:

1. Insert the DVD into your PC's DVD drive.
2. Run your previously installed DVD player application and select Play.
3. Navigate the DVD menus as you would any standard DVD video. Any Web links in the DVD Extras section must be manually entered into your browser.

Most DVD drives include a decoder/player application. If you do not currently have a DVD decoder/player installed on your system, you can do one of the following:

■ Play the disc in a standard set-top DVD player.
■ Use an existing DVD decoder with Windows Media Player 9 or later (visit www.microsoft.com/windows/windowsmedia).
■ Purchase a DVD decoder to use with Windows Media Player, such as the plug-in available from Cyberlink (www.gocyberlink.com/winxp_plugin/dvd_se).
■ Purchase a complete decoder/player combination, such as PowerDVD by CyberLink (www.gocyberlink.com), WinDVD by Intervideo (www.intervideo.com), or SoftDVD by MGI (www.mgisoft.com).

Here's how to access the Technical Reference files, previous editions of the book, and any other files on the DVD-ROM:

1. Insert the DVD into your PC's DVD drive.
2. Open My Computer.
3. Right-click the icon for the DVD drive containing the disc.
4. Select Explore.
5. Navigate through the folders and files just as if you were viewing files stored on your computer's hard drive.

Note

Many of the documents included in the Extras section of the DVD are in PDF format, which requires Adobe Acrobat to view. Acrobat is included free on the DVD, and updates to Acrobat can be found at www.adobe.com.

If you like the in-depth video content on this DVD, a longer 6-hour version with many more individual segments is available in my Upgrading and Repairing PCs Video Training Course. For more information on the full 6-hour Upgrading and Repairing PCs Video Training Course, see www.upgradingandrepairingpcs.com.

System Requirements for DVD-ROM Video

The minimum system configuration is as follows:

■ Intel Celeron/Pentium or AMD Duron/Athlon processor, 400MHz
■ Windows 98 Second Edition, Me, 2000, or XP
■ 64MB of RAM (Windows 2000 and XP require 128MB of RAM)
■ 4MB graphics card, 800×600 resolution, 16-bit color
■ Direct Sound–compatible sound card
■ 4X DVD-ROM drive (UDMA enabled)
■ Direct Show–compliant DVD decoder/player software installed
■ DirectX 7.0
■ Internet Explorer 5.0

Access to DVD Content Without a DVD Player or DVD Drive

If you do not have a set-top DVD player or DVD drive, you can still access all the files included on the DVD-ROM by visiting www.upgradingandrepairingpcs.com. To access these materials on the Web, follow these steps:

1. Remove the DVD from the package insert and note the password on the DVD label.
2. Visit www.upgradingandrepairingpcs.com and follow the DVD link from the home page.
3. Enter your password as included on the DVD label.
4. You can then download any of the files provided there, including Windows Media Player versions of the videos, multiple previous editions in PDF format, a hard drive specification database, a vendor database, and more.
