Introduction

The Configuring Windows Devices exam (70-697) is separated into nine sets of objectives. This book contains nine chapters that clearly detail what those objectives are and the content that you can expect to see on the exam. Because each chapter covers a part of the exam you should concentrate on one chapter at a time and complete the thought experiments and review questions. This book covers the general, high-level knowledge you need to know to answer questions regarding why and when you might actually perform tasks relating to the exam objectives.

Prior to taking the exam you should fully prepare to the best of your ability and we assume that you have some practical experience supporting Windows devices within the workplace. You are also probably reading this book as part of your final preparations and that you feel almost ready to take the exam.

In this book we have included how-to steps and walkthroughs whenever we feel that they are useful and we hope that you will perform the tasks on your system or within a virtual machine to crystalize your knowledge. Throughout the book there are numerous notes and links to resources on the Internet which should add even more depth to your preparation. We expect that Windows 10 will evolve constantly, through Windows upgrades and you should always supplement your learning with practical experience obtained by using the latest build of the operating system as there are always new things to learn and fresh challenges to master.

This book covers every exam objective, but it does not cover every exam question. Only the Microsoft exam team has access to the exam questions themselves and Microsoft regularly adds new questions to the exam, making it impossible to cover specific questions. You should consider this book a supplement to your relevant real-world experience and other study materials. If you encounter a topic in this book that you do not feel completely comfortable with, use the links you'll find in text to find more information and take the time to research and study the topic. Great information is available on MSDN, TechNet, and in blogs and forums.

Microsoft certifications

Microsoft certifications distinguish you by proving your command of a broad set of skills and experience with current Microsoft products and technologies. The exams and corresponding certifications are developed to validate your mastery of critical competencies as you design and develop, or implement and support, solutions with Microsoft products and technologies both on-premises and in the cloud. Certification brings a variety of benefits to the individual and to employers and organizations.

MORE INFO ALL MICROSOFT CERTIFICATIONS

For information about Microsoft certifications, including a full list of available certifications, go to <http://www.microsoft.com/learning>.

Acknowledgments

I would like to thank Karen Szall for the opportunity to write for Microsoft Press again, and Jason Kellington, my co-author for the valuable insights during the early stages of the writing process. This book is dedicated to Annette and Tommy, Annette has been a rock during the summer. Mwah!

-Andrew

Many thanks to Karen Szall and the great team at Microsoft Press, and to my co-author Andrew Bettany for your tireless work and preparation of this book. It has truly been a pleasure. To my wife and boys: The pages penned herein would not be possible without your support, patience, and love. Thank you.

-Jason

Free ebooks from Microsoft Press

From technical overviews to in-depth information on special topics, the free ebooks from Microsoft Press cover a wide range of topics. These ebooks are available in PDF, EPUB, and Mobi for Kindle formats, ready for you to download at:

<http://aka.ms/mspressfree>

Check back often to see what is new!

Microsoft Virtual Academy

Build your knowledge of Microsoft technologies with free expert-led online training from Microsoft Virtual Academy (MVA). MVA offers a comprehensive library of videos, live events, and more to help you learn the latest technologies and prepare for certification exams. You'll find what you need here:

<http://www.microsoftvirtualacademy.com>

Errata, updates, & book support

We've made every effort to ensure the accuracy of this book and its companion content. You can access updates to this book—in the form of a list of submitted errata and their related corrections—at:

<http://aka.ms/ER697/errata>

If you discover an error that is not already listed, please submit it to us at the same page.

If you need additional support, email Microsoft Press Book Support at *mspinput@microsoft.com*.

Please note that product support for Microsoft software and hardware is not offered through the previous addresses. For help with Microsoft software or hardware, go to *<http://support.microsoft.com>*.

We want to hear from you

At Microsoft Press, your satisfaction is our top priority, and your feedback our most valuable asset. Please tell us what you think of this book at:

<http://aka.ms/tellpress>

The survey is short, and we read every one of your comments and ideas. Thanks in advance for your input!

Stay in touch

Let's keep the conversation going! We're on Twitter: *<http://twitter.com/MicrosoftPress>*.

Preparing for the exam

Microsoft certification exams are a great way to build your resume and let the world know about your level of expertise. Certification exams validate your on-the-job experience and product knowledge. Although there is no substitute for on-the-job experience, preparation through study and hands-on practice can help you prepare for the exam. We recommend that you augment your exam preparation plan by using a combination of available study materials and courses. For example, you might use the Exam ref and another study guide for your “at home” preparation, and take a Microsoft Official Curriculum course for the classroom experience. Choose the combination that you think works best for you.

Note that this Exam Ref is based on publicly available information about the exam and the author’s experience. To safeguard the integrity of the exam, authors do not have access to the live exam.

This page intentionally left blank

Manage identity

Identity is an important concept in Windows, and the Manage Identity objective domain will test your understanding of how identities are managed in Windows to provide users with a consistent and secure environment. You'll also need to know how to support Windows Store and Office 365 apps, install apps into images, and support authentication and permissions mechanisms in Windows.

Objectives in this chapter:

- Objective 1.1: Support Windows Store and cloud apps
- Objective 1.2: Support authentication and authorization

IMPORTANT
*Have you read
page xix?*

It contains valuable information regarding the skills you need to pass the exam.

Objective 1.1: Support Windows Store and cloud apps

This objective covers supporting and installing apps from a variety of sources, including Windows Store, Microsoft Office 365, and Windows Intune. You'll see how to use a Microsoft account to synchronize app and Windows settings across multiple devices. You'll also see how to install apps into Windows Imaging Format (WIM) images, and manage the installation and availability of apps, including sideloading and deep linking.

This objective covers how to:

- Integrate Microsoft account and personalization settings
- Install and manage software with Microsoft Office 365 and Windows Store apps
- Sideload apps into online and offline images
- Sideload apps by using Microsoft Intune
- Deep link apps by using Microsoft Intune

Integrate Microsoft account and personalization settings

Using a Microsoft account with Windows 10 is the simplest and quickest way for users to maintain a consistent environment across multiple devices. Windows 10 can use a Microsoft account to save Personalization settings to the cloud and synchronize those settings across

devices including PCs, laptops, tablets, and smartphones. In Windows 10, you can associate a Microsoft account with two separate account types:

- **Local account** A local account is stored in the local Security Account Manager (SAM) database on a Windows 10 computer.
- **Domain account** A domain account is stored in the Active Directory Domain Services (AD DS) database on a domain controller. Domain accounts can be used to authenticate a user on Windows computers joined to the domain.

A Microsoft account can provide settings synchronization across local and domain accounts. For example, a user might associate his Microsoft account with a local account on his home computer and a domain account at work. With this configuration, the user can have settings like Internet Explorer favorites or app configuration settings remain consistent regardless of which computer he is signed in to.

Associating a Microsoft account with a local or domain account

You can associate a Microsoft account with a local or domain account from the Your Account page in the Settings app.

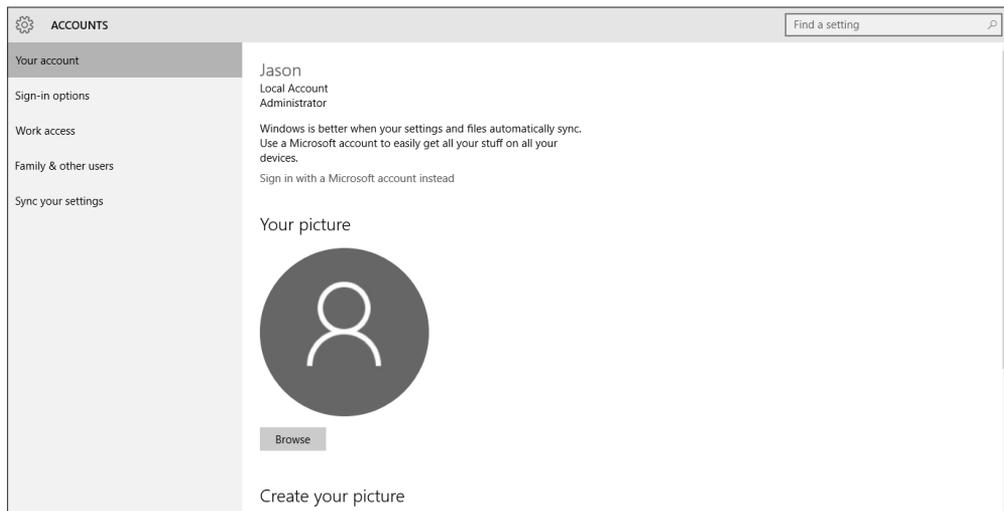

FIGURE 1-1 The Your Account page in the Settings app

To associate a Microsoft account with a local Windows account, complete the following steps:

1. From the Desktop, click the Start button, and then click Settings.
2. In the Settings app, click Accounts.

3. In the left pane of the Accounts page, click Your Account.
4. In the Your Account page, click Sign In With A Microsoft Account Instead.
5. Enter your Microsoft account user name and password, and then click Signin.
6. You will be asked to verify your identity to be able to associate the account.
7. After verification, click Switch To Start Using Your Microsoft Account to sign in to Windows.

To associate a Microsoft account with a domain account, complete the following steps:

1. When logged in with a domain account, from the Desktop, click the Start button, and then click Settings.
2. In the Settings app, click Accounts.
3. On the Accounts page, click Your Account.
4. In the Your Account box, click Sign In With A Microsoft Account.
5. On the Connect To A Microsoft Account On This PC page, select the PC settings you want to sync with the domain, and then click Next. The options are:
 - Start Screen
 - App Data
 - Appearance
 - Language Preferences
 - Desktop Personalization
 - Ease Of Access
 - Apps
 - Other Windows Settings
 - Passwords
 - Web Browser
6. Enter your Microsoft account user name and password, and then click Next.
7. You will be asked to verify your identity to continue associating the account.
8. After verification, click Connect to associate your Microsoft account with your domain account.

Configuring Microsoft account synchronization settings

Users can change which items they opt to synchronize by using a Microsoft account. Users can access the options in the Settings app from the Sync Your Settings section of the Accounts page (see Figure 1-2).

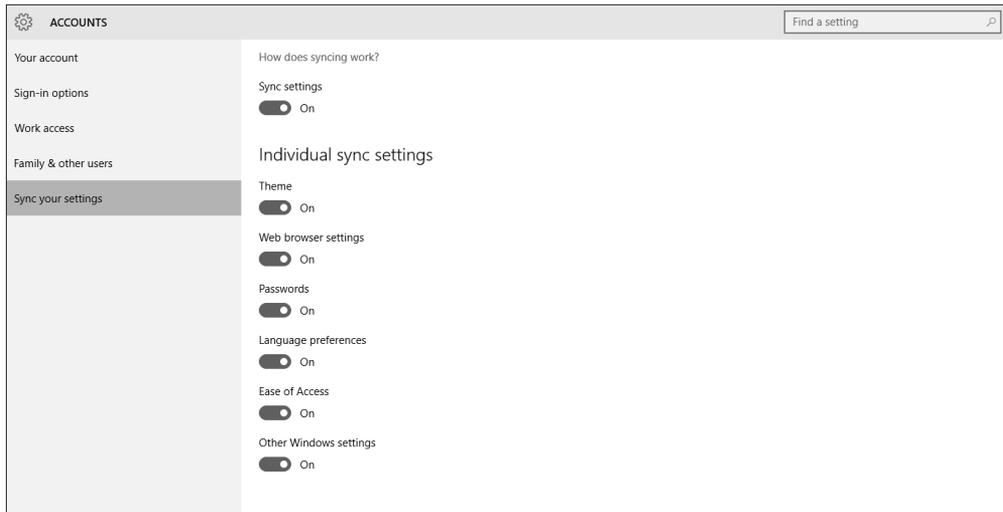

FIGURE 1-2 The Sync Your Settings section in the Settings app

Configuring Microsoft account settings by using Group Policy

Network administrators can incorporate Microsoft accounts into the workplace to help users transfer what they've configured with their domain accounts between computers by using a Microsoft account. Network administrators can also disable the ability to associate Microsoft accounts by setting limitations in Group Policy. This section looks at the Group Policy options for controlling the association of Microsoft accounts.

The Group Policy setting used to disable Microsoft account use is named Accounts: Block Microsoft Accounts, and the setting is found in Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options (see Figure 1-3). You can choose from three different settings:

- **The policy is disabled** If you disable or do not configure this policy, users will be able to use Microsoft accounts with Windows.
- **Users can't add Microsoft accounts** If you select this option, users will not be able to create new Microsoft accounts on this computer, switch a local account to a Microsoft account, or connect a domain account to a Microsoft account. This is the preferred option if you need to limit the use of Microsoft accounts in your enterprise.
- **Users can't add or log on with Microsoft accounts** If you select this option, existing Microsoft account users will not be able to log on to Windows. Selecting this option might make it impossible for an existing administrator on this computer to log on and manage the system.

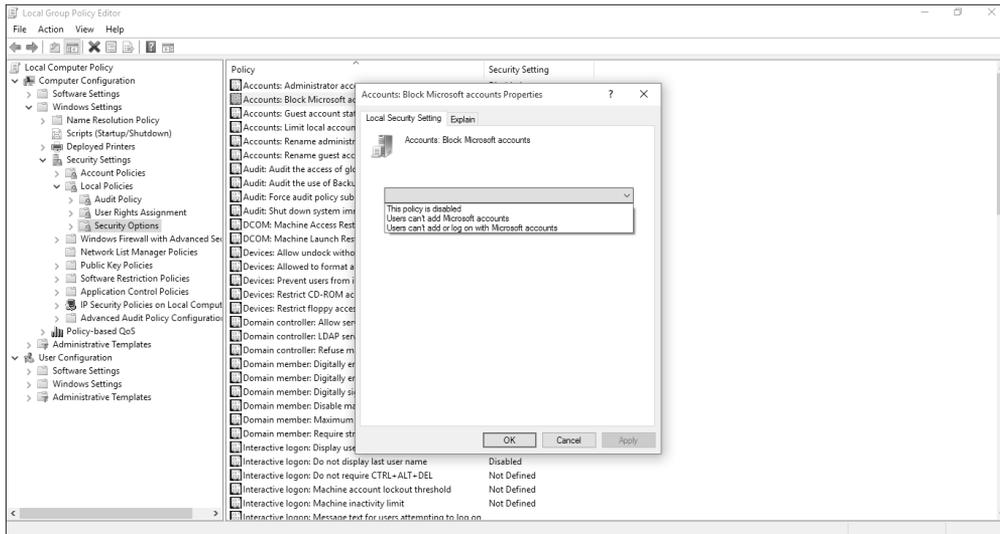

FIGURE 1-3 The Accounts: Block Microsoft Accounts Properties dialog box in Local Group Policy Editor

Install and manage software

While you can install apps using conventional methods, such as choosing Add/Remove Programs in Control Panel, or removable media, you can also perform cloud-based software installation by using Windows Store or Microsoft Office 365.

Installing apps by using Microsoft Office 365

Microsoft Office 365 is Microsoft Office in the cloud, accessible via a user-based paid subscription. Because it's cloud-based, users can access the Microsoft Office products that are licensed to them on up to five compatible devices.

Office 365 updates are applied automatically. There's no need for software maintenance tasks, such as installing updates or upgrading versions, so enterprise administrators don't need to worry about updating devices manually. However, they're still in control of updates and can decide how and when these will be provided to users. Administrators can also decide where users' data should be stored: on the on-premises data servers of a company, in private cloud-based storage, in the public cloud, or a combination of these.

Office 365 is software as a service (SaaS). With SaaS, the user is provided a software product that they can use and consume, on demand. An organization might choose a SaaS product like Office 365 to reduce maintenance and installation workloads, reduce licensing costs, or simplify the organization software portfolio. SaaS products like Office 365 also offer the benefit of access to apps and saved documents from any location or computer, provided an Internet connection is available.

MORE INFO EXPLORING OFFICE 365

This Exam Ref focuses on installing Office 365 components. However, there is much more to Office 365, including conferencing, email, secure file sharing, and website hosting. You can learn more about Office 365 at <https://products.office.com/en-ca/business/explore-office-365-for-business>.

CONFIGURING OFFICE 365

You can obtain a free trial subscription to Office 365 Business Premium by visiting the following link: https://portal.office.com/Signup/Signup.aspx?OfferId=467eab54-127b-42d3-b046-3844b860bebf&dl=O365_BUSINESS_PREMIUM&culture=en-US&country=US&ali=1&alo=1&lc=1033#0. After signing up, you can perform the initial configuration steps on the Office 365 Admin Center page, pictured in Figure 1-4.

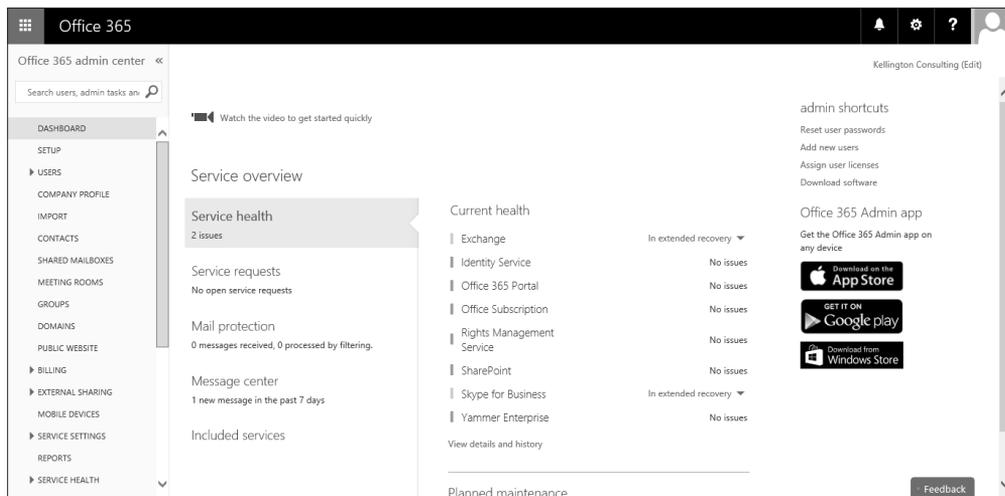

FIGURE 1-4 The Office 365 Admin Center page

After signing up, you can access the Office 365 Admin Center at <https://portal.microsoftonline.com/admin/default.aspx>.

INSTALLING OFFICE FROM THE OFFICE 365 PORTAL

You can configure several settings that control the ability to install Office apps from Office 365 Admin Center. From the User Software page under Service Settings in Office 365 Admin Center, you can select the applications that you will enable users to install, one of the options being Office And Skype For Business. If this option is selected, users can install Office on their computers by completing the following steps:

1. Open a web browser and navigate to <https://portal.microsoftonline.com>.
2. Sign in with the appropriate user name and password.
3. From the Office 365 portal page, click Install Now.

4. Click Run to start the installation, click Yes to continue, and click Next to start the wizard.
5. Select No Thanks to not send updates to Microsoft, and then click Accept.
6. Click Next on the Meet OneDrive page.
7. Click Next to accept defaults, select No Thanks, and then click All Done.

DEPLOYING OFFICE

You can also deploy Office in the enterprise using methods other than the self-service method explained above. The Office Deployment tool enables you to configure information about which language(s) to download, which architecture to use, where the software deployment network share is located, how updates are applied after Office is installed, and which version of the software to install. Deployment methods include Group Policy, startup scripts, or Microsoft System Center Configuration Manager.

Managing software by using Office 365

You can manage all aspects of the Office 365 environment from Office 365 Admin Center. The admin center contains configuration and management pages for all the different features that affect Office app installation:

- **Dashboard** This page provides a view of overall service health, including Office-related components. It also contains shortcuts to administrative tasks, such as Reset User Passwords and Add New Users.
- **Users** From this page, you can add, remove, and edit user accounts that are part of the Office 365 environment. You can also configure Active Directory synchronization and configure authentication methods and requirements.
- **Domains** From this page, you can manage and add domains used by Office 365.
- **Service Settings** There are several pages available under the Service Settings menu, including Updates, User Software, Passwords, Rights Management, and Mobile.
- **Tools** This page includes several important configuration and readiness tools for Office, including:
 - Office 365 health, readiness, and connectivity checks
 - Office 365 Best Practices Analyzer
 - Microsoft Connectivity Analyzer

IMPORTANT OFFICE 365 FEATURES

There are other important features of Office 365 that you need to consider in preparation for the exam. While these topics are not covered in great detail, they might appear as supporting information for a scenario or question on the exam.

- **Click-to-Run** You can configure a click-to-run installation of Office that enables a streamed installation process, which gives almost instant access to Office desktop ap-

plications, rather than the traditional installation method that requires the user to wait for the entire installation process to complete before using any Office applications.

- **Windows PowerShell** You can use Windows PowerShell to manage Office 365. You need to be familiar with the common Office 365 management cmdlets. You can find out more about Office 365 management using Windows PowerShell here: <https://technet.microsoft.com/en-us/library/dn568031.aspx>.

Installing apps by using the Windows Store

The Windows Store is the standard source for Windows 10 apps, and the most common method for installing those apps. The Windows Store is installed by default on all Windows 10 computers.

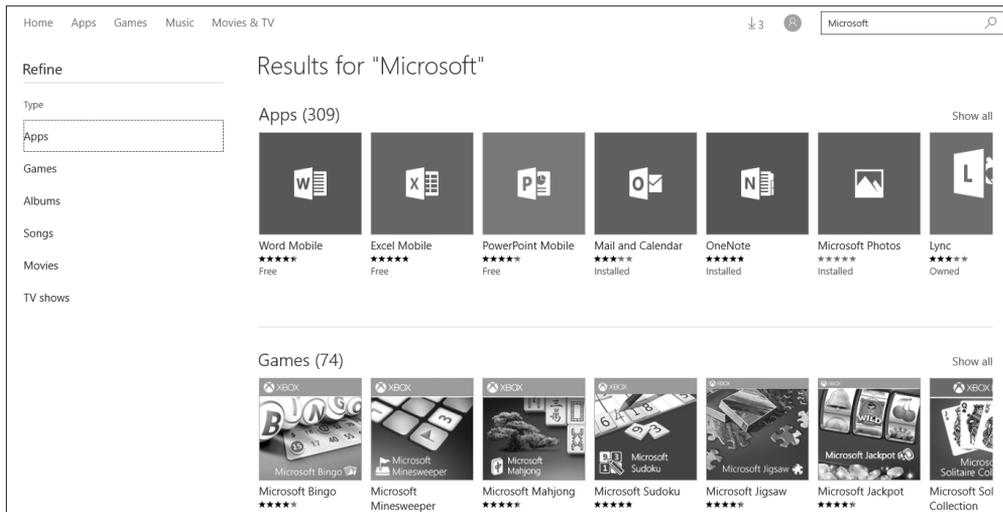

FIGURE 1-5 The Windows Store

There are several aspects of the Windows Store that you need to be aware of for the exam:

- The Windows Store is the primary repository and source for apps that are created and made available to the public, as a free trial or paid app.
- Users must have a Microsoft account associated with their local or domain account in order to download any apps from the Windows Store.
- Windows Store apps designed for Windows 10 are universal apps. They will function on Windows 10 computers, tablets, and mobile phones or smart devices, as well as Xbox.
- Windows Store apps are limited to 10 devices per Microsoft account. A user can install an app on up to 10 devices that are associated with his or her Microsoft account.
- Apps designed for non-public use—that is, for a specific organization—can be submitted through the Windows Store and be made available only to members of the organization.

MORE INFO WINDOWS STORE APPS VS. WINDOWS DESKTOP APPS

This objective domain covers only Windows Store apps. Desktop apps, which appear and behave much like traditional Windows programs, are covered in Chapter 8.

To install a Windows Store app, open the Windows Store while logged in to Windows with a Microsoft account. You can navigate the Windows Store by browsing the categories provided at the top of the window, or by using the Search toolbar, also at the top of the window. After you've located the app you want to install, click Install on the app page. The app installs in the background, and you are notified when the installation is complete. Installed apps are available from the Start menu, by clicking All Apps, or by typing the name of the app in the Search field. You can also pin apps to the Start menu or taskbar to make them easier to access.

DISABLING ACCESS TO THE WINDOWS STORE

By default, the Windows Store is accessible to all users who have a Microsoft account associated with their local or domain account. Access to the Windows Store can be disabled by using Group Policy. You might disable access for a number of reasons, including controlling apps that are available on certain computers, such as kiosk or terminal computers, satisfying legal or compliance-related requirements, or ensuring that only approved applications of your organization are installed on Windows computers.

To disable access to the Windows Store, open either the Local Group Policy Editor, or Group Policy Management on a domain controller for domain policy. Within Group Policy, navigate to the following location: Computer Configuration\Administrative Templates\Windows Components\App Package Deployment. Change the setting for Allow All Trusted Apps To Install to Disabled.

EXAM TIP

Changes to Group Policy do not take place until a Group Policy refresh occurs. By default, this is every 90 minutes. To force a refresh, you can run **gpupdate /force** from the command prompt.

Sideload apps into offline and online images

Organizations sometimes create their own apps. These apps have the same characteristics as the apps you find in the Windows Store (which aren't desktop apps). As noted earlier, enterprise administrators can make these apps available publicly if they want to go through the Windows Store certification process, or they can make them available to their enterprise users through a process known as sideloading.

Enabling sideloading in Windows 10

By default, the sideloading option in Windows 10 is disabled. To enable sideloading, you need to use a Group Policy setting. To configure Group Policy so that computers can accept and install sideloaded apps that you created for your organization, navigate to Computer Configuration/ Administrative Templates/ Windows Components/ App Package Deployment. Double-click Allow All Trusted Apps To Install. When this setting is enabled, any line of business (LOB) Windows Store app, signed by a Certification Authority (CA) that the computer trusts, can be installed.

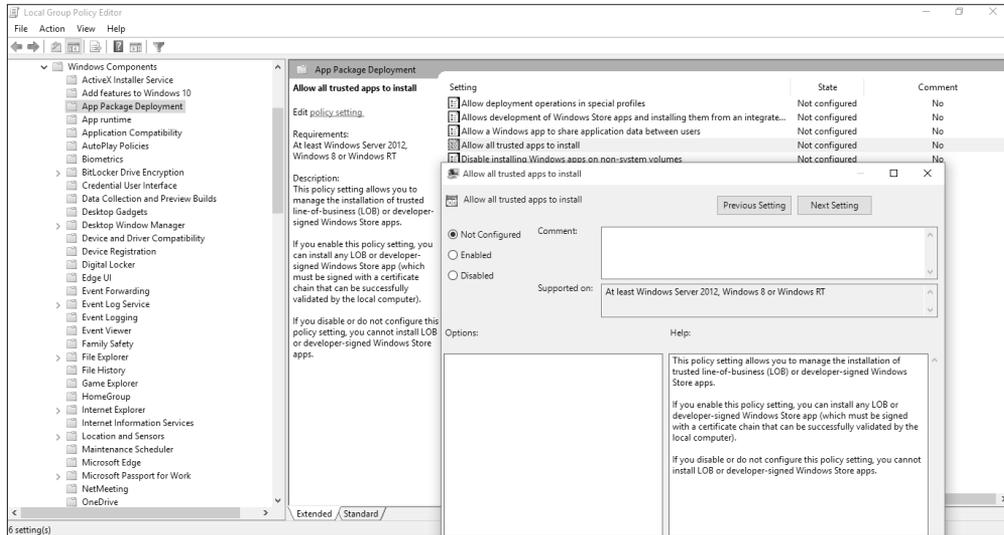

FIGURE 1-6 Group Policy setting Allow All Trusted Apps To Install

Sideloaded an app

After sideloading is enabled in Group Policy, you can sideload the app using the AppX Windows PowerShell module and the associated cmdlets. To manually sideload an app for the currently logged in user, perform the following steps from a Windows PowerShell prompt:

1. Type **Import-module appx**. Press Enter.
2. Type **Add-appxpackage "path and name of the app"** to add the app. Press Enter. Table 1-1 shows the available AppX cmdlets. If you need to add app dependencies, the command should look more like this: **Add-appxpackage C:\MyApp.appx DependencyPath C:\appplus.appx**.

The app installs, and then is available to the user. This needs to be done for each user if multiple users share a single computer.

EXAM TIP

Some exam questions require you to solve a problem with more than one Windows component or tool. For example, you might be asked how you would deploy an app to all client computers in a domain and configure the app to access network resources. The answer will likely include applying a specific Group Policy Object (Allow All Trusted Apps To Install) and using a Windows PowerShell cmdlet (such as `add-appxpackage`).

The AppX module for Windows PowerShell includes several cmdlets that you can use to install and manage LOB Windows Store apps.

Table 1-1 Cmdlets in the AppX module for Windows PowerShell

Cmdlet	Description
<code>Add-AppxPackage</code>	To add a signed app package to a single user account
<code>Get-AppxLastError</code>	To review the last error reported in the app package installation logs
<code>Get-AppxLog</code>	To review the app package installation log
<code>Get-AppxPackage</code>	To view a list of the app packages installed for a user profile
<code>Get-AppxPackageManifest</code>	To read the manifest of an app package
<code>Remove-AppxPackage</code>	To remove an app package from a user account

If you want to sideload the apps to multiple computers, use Deployment Image Servicing and Management (DISM) cmdlets. You can use DISM commands to manage app packages in a Windows image. When you use DISM to provision app packages, those packages are added to a Windows image, and are installed for the desired users when they next log on to their computers.

You need to be familiar with the DISM syntax when servicing a Windows image, whether a computer is offline or online. Table 1-2 lists a few cmdlets to keep in mind.

Table 1-2 Cmdlets in the AppX module for Windows PowerShell

Cmdlet	Description
<code>DISM.exe {/Image:<path_to_image_directory> /Online} [dism_global_options] {servicing_option} [<servicing_argument>]</code>	To service a Windows image with DISM
<code>DISM.exe /Image:<path_to_image_directory> [/Get-ProvisionedAppxPackages /Add-ProvisionedAppxPackage /Remove-ProvisionedAppxPackage /Set-ProvisionedAppxDataFile]</code>	To service an app package (.appx or .appxbundle) for an offline image
<code>DISM.exe /Online [/Get-ProvisionedAppxPackages /Add-ProvisionedAppxPackage /Remove-ProvisionedAppxPackage /Set-ProvisionedAppxDataFile]</code>	To service an app package (.appx or .appxbundle) for a running operating system

Other command-line service options include `/Get-ProvisionedAppxPackages`, `/FolderPath`, `/PackagePath`, `/LicensePath`, and `/Add-ProvisionedAppxPackage`. Becoming familiar with these is very important because you'll likely be tested on them. You can learn about all available commands and options at <http://technet.microsoft.com/en-US/library/hh824882.aspx>. Review this article and make sure that you can make sense of commands you might come across, perhaps one that looks like:

```
Dism /Online /Add-ProvisionedAppxPackage /FolderPath:C:\Test\Apps\MyUnpackedApp /SkipLicense
```

Or it looks like this:

```
Dism /Image:C:\test\offline /Add-ProvisionedAppxPackage /FolderPath:c:\Test\Apps\MyUnpackedApp /CustomDataPath:c:\Test\Apps\CustomData.xml
```

Sideload apps by using Microsoft Intune

You can use Microsoft Intune to sideload apps via the cloud and make them available to any authorized, compatible device that's connected to the Internet. The following list outlines the high-level steps that you need to complete to sideload an app using Microsoft Intune.

1. Add users and create groups, if applicable.
2. Upload the app to Microsoft Intune.
3. Choose the users, groups, computers, and devices that can download the app, and link them (user-to-device).
4. For the self-service model in this example, choose how to deploy the app. It can be available, or available and required.
5. Verify that the app is available in the Windows Intune Company Store, and use the Company Store to install the app on devices.

Adding a user and groups

You can add users and groups to assist you in deploying your app to the appropriate audience. In Figure 1-7, you can see the Groups page, where new users and groups can be added to Intune. If you are adding users to a group, the group must be created before the user can be added to the group.

FIGURE 1-7 The Microsoft Intune Groups page

Uploading an app to Microsoft Intune

You can upload an app from the Apps page of Microsoft Intune, as shown in Figure 1-8.

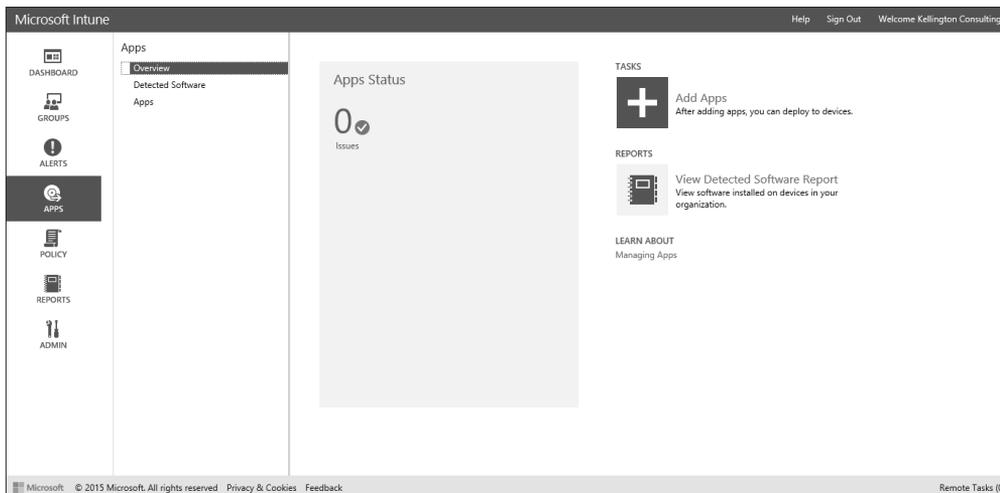

FIGURE 1-8 Uploading to the Microsoft Intune Apps page

To upload an app, complete the following steps:

1. On the Apps page, click Add Apps.
2. In the software setup window, select Windows app package as the software installer file type.
3. Click Browse, locate the .appx or .appxbundle file to upload, and then click Open.

4. Fill out the description information for the app.
5. Specify the architecture requirements.
6. Specify any rules to deal with previously installed apps.
7. Click Upload to upload the app to Microsoft Intune.

Once uploaded, the app will be available within the administration console to assign to users or groups (see Figure 1-9).

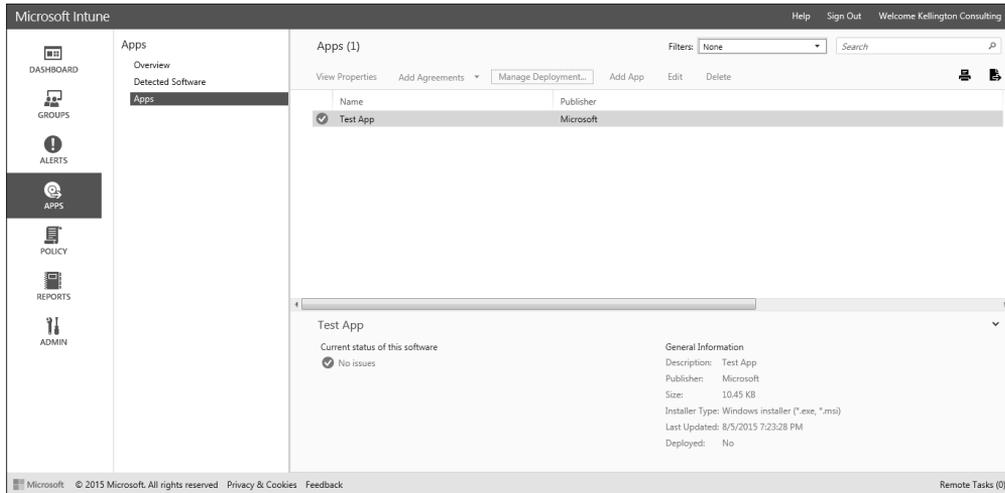

FIGURE 1-9 Available apps on the Apps page in the Microsoft Intune console

Choosing the users who can install the app

You can choose the users to whom the app is made available by selecting **Manage Deployment** on the Apps page, as shown in Figure 1-9. When you start the **Manage Deployment Wizard**, you will be prompted to choose one or more groups to which the app is assigned, as in Figure 1-10. You can choose to assign the apps to users or computers. You need to also choose the **Deployment Action** for the app, although there is only one option available for each group type. For computer groups, you need to choose **Required Install**, and for user groups, you need to choose **Available Install**. Once you've chosen your options, you can click **Finish** to complete the group assignment process.

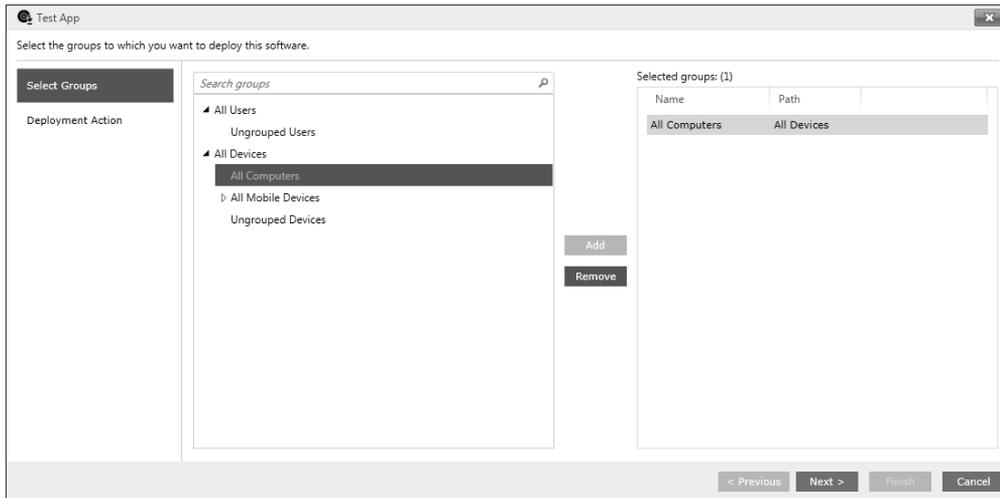

FIGURE 1-10 Choosing deployment groups

Installing the app from the Company Store

To install the app, your users will navigate to the Company Store page, and select the app from the Company Store page.

Deep link apps using Microsoft Intune

You can make Windows Store apps available to Windows RT users in your company portal by using Windows Intune as well as Configuration Manager. This section focuses on Windows Intune. You'll follow the same basic process as you did when deploying an app via the Installed Software option, but this time you choose External Link in the Add Software Wizard. Before you begin, decide which Windows Store app you want to deploy. For this example, choose OneDrive for Business.

The first part of the process requires you to obtain the link to the app you want to add to your company portal. To obtain the link for OneDrive for Business, follow these steps:

1. From the Start menu, type **Store**, and then click Store.
2. Search for Word Mobile, and then click it to access the installation page.
3. On the Word Mobile page, click Share.
4. In the Share area, click Mail.
5. The email contains the link. Send this link to yourself, copy the link, and paste it into Notepad, or otherwise make the link accessible for later.

The second part of the deep-linking process involves adding the app to Windows Intune:

1. Log on to the Microsoft Intune Administrator console.
2. Click the Apps tab, and then click Add Apps.

3. Wait for the Microsoft Intune Software Publisher to install, and then enter your Microsoft Intune credentials.
4. In the Microsoft Intune Software Publisher window, click Next.
5. On the Software setup page, select External link, and then type the link you copied in step 5 of the previous task into the URL field, and then click Next.
6. Carefully input the information to describe the software. What you input can be viewed by your employees. Click Next when finished.
7. Verify that the information is correct, and then click Upload.
8. After the upload is complete, click Close.

Thought experiment

Managing Microsoft Office in a small organization

In this thought experiment, apply what you've learned about this objective. You can find answers to these questions in the "Answers" section at the end of this chapter.

You manage a small business that has seven employees, and each employee has multiple devices that they use to perform work. You don't have an Active Directory domain. Sometimes the users are at the company, sometimes at home, and often in a hotel. Users don't always have Internet access.

Users complain that they can't always access their work documents and that when they use Microsoft Office on their devices, they get a different user experience on all of them. Their settings and preferences need to be reset repeatedly for each device as they change them. You want to resolve these problems (and others, including mandating Microsoft Office updates), but you don't have a lot of money to spend.

1. What should you set up to resolve all these issues, all without incurring a substantial expense?
2. Where would you store the users' data?
3. If you want to delegate some of the responsibilities for managing your solution, what types of administrator would you create to manage support tickets?

Objective summary

- You can integrate users' Microsoft accounts into your organization to enable synchronization of settings between multiple devices.
- You can manage apps by using Office 365, DISM, and Microsoft Intune.
- You can configure Group Policy to manage apps, manage access to the Windows Store, and enable sideloading.
- You can sideload apps to enable LOB apps without making them available through the Windows Store.

Objective review

Answer the following questions to test your knowledge of the information in this objective. You can find the answers to these questions and explanations of why each answer choice is correct or incorrect in the “Answers” section at the end of this chapter.

- 1.** Where can you configure a Group Policy that restricts the use of Microsoft accounts for a specific group of users in an Active Directory domain?
 - A.** In the Group Policy Management Editor window, by expanding Computer Configuration/ Policies/ Windows Settings/ Security Settings/ Local Policies/ Security Options
 - B.** In the Group Policy Management Editor window, by expanding Computer Configuration/ Policies/ Windows Settings/ Security Settings/ Local Policies/ User Rights Assignment
 - C.** In the Local Group Policy Editor, by navigating to Computer Configuration/ Windows Settings/ Security Settings/ Local Policies/ Security Options
 - D.** In the Local Group Policy Editor, by navigating to Computer Configuration/ Windows Settings/ Security Settings/ Local Policies/ User Rights Assignment
- 2.** Where can users associate a Microsoft account with a domain account?
 - A.** Users can't do this. Only administrators can perform this task in Active Directory Users And Computers on a domain controller.
 - B.** In the Settings app, on the Accounts page
 - C.** In the Group Policy Management Editor by expanding Computer Configuration/ Policies/ Windows Settings/ Local Policies/ Security
 - D.** In the Settings app, on the Personalization page.
- 3.** Which of the following can you manage in the Office 365 Admin Center?
 - A.** Active Directory synchronization
 - B.** Valid, expired, and assigned licenses
 - C.** User password, including resetting
 - D.** All of the above
 - E.** B and C only
- 4.** Which of the following tools and technologies can help you sideload LOB apps for computers in your organization?
 - A.** DISM
 - B.** Windows PowerShell
 - C.** Configuration Manager
 - D.** Microsoft Intune
 - E.** All of the above
 - F.** Only C and D

5. Which Group Policy setting do you have to enable before you can sideload apps in Windows 10?
 - A. None
 - B. Allow All Trusted Apps To Install
 - C. Allow Development Of Windows Store Apps
 - D. Block Microsoft Accounts
6. True or false: You can create a required installation for an app in Microsoft Intune, which will automatically install on devices.
 - A. True
 - B. False
7. Which of the following describes the purpose of deep linking an app?
 - A. To make specific Windows Store apps available through the company portal
 - B. To force the installation of apps on Windows 10 computers
 - C. To add LOB apps to the Windows Store
 - D. None of the Above

Objective 1.2: Support authentication and authorization

Users need to be authenticated to access a computer or network before they can be authorized to access the resources on it. Windows 10 supports several authentication mechanisms and methods, and different ways to manage accounts. This chapter will help you to understand the important concepts needed to support Windows 10 authentication and authorization.

This objective covers how to:

- Support user authentication, including multi-factor authentication, certificates, virtual smart cards, picture passwords, and biometrics
- Support workgroup, homegroup, and domain membership, including Secure Channel, account policies, credential caching, and Credential Manager
- Know when to use a local account versus a Microsoft account
- Configure Workplace Join
- Configure Windows Hello

Support user authentication

User authentication can come in many forms in Windows 10. You need to understand the various methods for authentication as well as the different mechanisms for managing and supporting authentication.

Understanding multi-factor authentication

Multifactor authentication requires two (or more) types of authentication to gain access to a device or network. Most often, one type is a password, and the other is something else, such as a smart card, fingerprint, or digital certificate. This section focuses a little more on certificates as a means of achieving authentication, but this book has covered this topic in various places, and you need to review those entries when you can (for the most part, certificates have been associated with apps, because apps must be signed to ensure that they can be trusted).

A digital certificate is issued by a Certificate Authority (CA), such as Verisign or Active Directory Certificate Services (AD CS) in Windows Server 2012 R2. The certificate can be used to provide proof that the identity asking for authentication is trusted and true, and that the identity offering it is also trusted and authentic. Authentication with certificates involves a public key and a private key that can be matched to provide that authentication. If no match occurs, no authentication is provided. You can learn more about Certificate Authorities at <http://technet.microsoft.com/en-us/library/cc732368.aspx>.

AD CS can issue and manage public key infrastructure (PKI) in a domain, provide public key cryptography and the ability to create digital certificates, and offer digital signature capabilities. For the purposes here, AD CS provides authentication by associating certificate keys with computers, users, and device accounts on a network. This is called binding.

For the exam, you might be asked how to enable users to access a network resource and be given a specific scenario. A scenario that includes AD CS will note that the network has its own PKI infrastructure. You need to understand that the required certificates must be available to the computer and the user, and they need to be stored in the proper location for authentication to be granted. Client certificates are stored in the Personal certificate store for the applicable user account on the client computer. Computer accounts need trusted root certificates to be stored in the Trusted Root Certification Authorities store, again on the client computer.

You can explore many other certificate folders as well. To view these stores on a local computer, type **certmgr.msc** in a Run dialog box, and click OK. Open this console and review the available certificate folders before moving on. Figure 1-11 shows a local computer, not connected to a domain, and the related Personal certificates. Typically, you'll see more certificates than those present in the example.

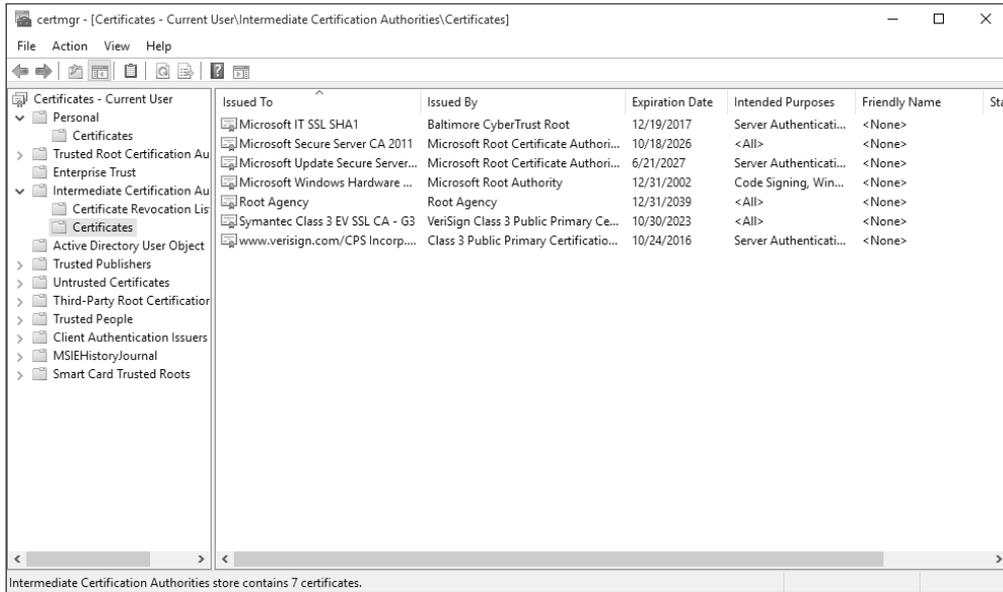

FIGURE 1-11 The Certmgr console

Understanding virtual smart cards

A virtual smart card works in the same general manner as a physical smart card does, but doesn't require a connected or installed smart card reader. Instead, the virtual smart card works with a Trusted Platform Module (TPM) chip, which protects the virtual card information through encryption, installed on the computer. As with other more advanced security options, you'll need a PKI domain infrastructure, complete with certificates and the ability to create and manage them, to incorporate this technology. Virtual smart cards offer the following:

- Authentication protection
- Confidentiality of the machine and its contents
- Private keys for security
- Encrypted card information that can't be mined or removed (that is, it can't be exported)
- Protection from rogue software that attacks at startup
- Multi-factor protection (smart card and PIN)

To use virtual smart cards, you need to meet more requirements than when you opt to use physical ones. These requirements include, but aren't limited to the following:

- Computers must be running Windows 8 or higher and Windows Server 2012 or higher.
- A compatible TPM must be installed on those computers that adhere to TPM 1.2 or higher standards.
- A limit of ten smart cards (virtual or physical) can be used on a single computer.

- The PIN and the PIN Unlock Key must be a minimum of eight characters. These can include numbers, letters, and special characters.

One very important command that you need to understand for the exam is `Tpmvscmgr.exe`, the command-line tool you use to configure a virtual smart card. You can use the command locally or remotely. Parameters you can use include `Create` and `Delete`. Examples include `/name` (the name of the smart card), `/admin key` (administrator key), `/PIN` (the PIN), `/generate` (to create the files in storage necessary for the card to function), and others listed at <http://technet.microsoft.com/en-us/library/dn593707.aspx>.

To configure a virtual smart card environment from scratch in a domain, you need to follow these steps:

1. Create a certificate template, a sixteen-step process performed on a Windows server in a domain that's installed with and running a CA, as outlined at http://technet.microsoft.com/en-us/library/dn579260.aspx#BKMK_Step1.

2. Create the virtual TPM smart card, a four-step process that uses the `Tpmvscmgr.exe` command with parameters, as outlined at http://technet.microsoft.com/en-us/library/dn579260.aspx#BKMK_Step2.

```
tpmvscmgr.exe create /name tpmvsc /pin default /adminkey random /generate
```

3. Enroll the certificate on the TPM virtual smart card, a six-step process, by using the `Certmgr.msc` console to add the certificate to the Personal store, as outlined at http://technet.microsoft.com/en-us/library/dn579260.aspx#BKMK_Step3.

MORE INFO VIRTUAL SMART CARDS

Learn more about virtual smart cards and be sure to explore the additional links on the left side of this page at <http://technet.microsoft.com/en-us/library/dn593708.aspx>.

To configure a Windows 10 virtual smart card on a stand-alone computer if you have the required technology and credentials available, follow these steps:

1. Open an elevated command prompt.
2. Type **tpm.msc**.
3. Verify that a compatible TPM can be found that's at least a TPM 1.2 or later. If you receive an error instead, but are sure a compatible module is available, enable it in the system BIOS before continuing.
4. Close the TPM management console.
5. At the command prompt, enter:

```
TpmVscMgr create /name MyVSC /pin default /adminkey random /generate
```

To provide a custom PIN value when creating the virtual smart card, use `/pin prompt` instead.

Configuring a picture password

A picture password is a way to log on to a computer by using a series of three movements consisting of lines, circles, and/or taps. You can pick any picture you want. Picture passwords can't be used to log on to domains; they are used to log on to stand-alone computers only. Picture password combinations are limitless because the pictures that can be used are limitless. Although picture passwords are considered more secure for stand-alone computers than typing a PIN or password, a hacker can get into a device by holding the screen up to light to see where most of the gestures are (by following the smudges on the screen). This is especially true if the user touches the screen only to input the password and rarely uses touch for anything else.

You create a picture password (or a four-digit PIN) from the Settings app:

1. Open the Settings app, and then click Accounts.
2. Click Sign-in Options.
3. Under Picture Password, click Add.
4. Input your current password, and then click Choose Picture to browse to and select the picture to use.
5. Follow the instructions in the resulting wizard to configure the picture password.

Exploring biometrics

Biometrics, like picture passwords, provides infinite possibilities for securing a computer and can be used as part of a multi-factor authentication plan (using it on its own isn't recommended). Biometric options are generally configured by incorporating a person's fingerprint and using a fingerprint reader (you "enroll" the user when configuring this), but you can also use a person's face, eye, or even their voice.

Microsoft has made using biometrics easier than ever by including native support for biometrics through the Windows Biometric Framework (WBF), which includes an option in the Settings app for configuring the device on Windows 10 computers. Windows now also includes Group Policy settings related to biometrics, and you can enable or disable this feature as desired. You need to review the information at <http://technet.microsoft.com/en-us/library/dn344916.aspx>, and locate the available Group Policy settings, just in case. You can find Local Group Policy options here (and follow the same general path in Group Policy): Computer Configuration/ Administrative Templates/ Windows Components/ Biometrics/, as shown in Figure 1-12.

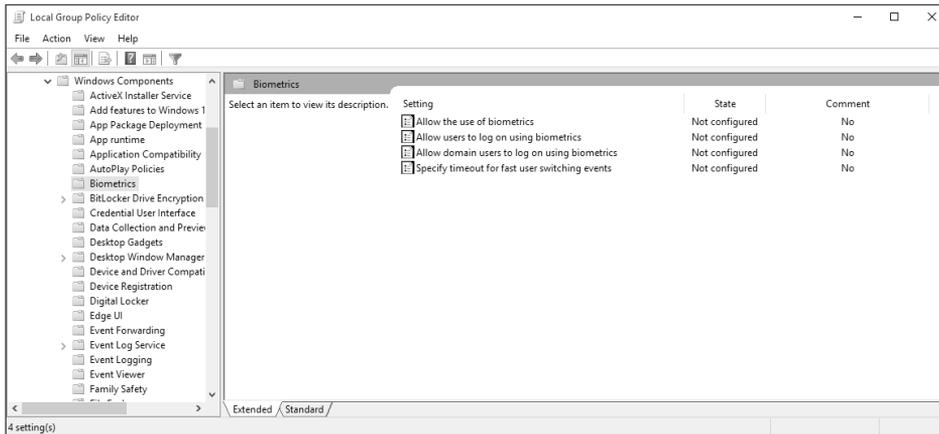

FIGURE 1-12 The Biometrics Group Policy settings

Support workgroup, homegroup, and domain membership

In this section, you'll review the differences between some similar technologies and network configurations, such as workgroup versus homegroup, workgroup versus domain, and credential caching versus Credential Manager.

Homegroups, workgroups, and domains

In almost all instances and scenarios, using a computer to complete tasks involves connecting to a network of some sort, even if it's just to access the Internet or to back up your work someplace other than your own PC. In homes, networked computers are often configured as homegroups. In a small business, the configuration is generally a workgroup. The purpose of both of these types of networks is frequently to share an Internet connection as well as files, folders, printers, and other resources. Domains are used in larger enterprises, which require more control and good protection of resource access. Domains are the only one of these three that employ AD DS to manage users, computers, and resources.

UNDERSTANDING HOMEGROUPS

A homegroup lets home users easily share documents, printers, and media with others on their private local network. This is the simplest kind of network sharing and is limited in what permissions and restrictions can be placed on the data shared. By default, all users that join a homegroup (only one per network) have read-only access to what's already shared by others. Users can reconfigure this, however, enabling both read and write access, if desired. When opting for a homegroup, users can:

- Create or join a homegroup from the prompt offered by Windows, assuming the network is configured as Private.

- Create or join a homegroup from the Network And Sharing Center, assuming the computers that want to join are running Windows 7, Windows 8, or Windows 10. Work through the applicable homegroup wizard to create or join a homegroup. Windows generates a random password other users will need to use to join.
- Share files from their original locations and their default libraries.
- Grant read-only or read/write access to the data they've shared.
- Limit access to only those network users who also have an account and password on their computers.
- Configure the same permissions for all network users, or set different permissions for individual users.

MORE INFO UNABLE TO CREATE A HOMEGROUP?

Creating a homegroup requires IPv6 to be installed on all of the computers in the homegroup. Computers within a homegroup must also be within 5 minutes of each other's system time in order for the homegroup to function properly. If you have problems with a homegroup, check for these two potential issues.

Because you can create and join a homegroup using a wizard, detailing the steps in this text isn't really necessary. However, you need to create a homegroup on your own local network and let other computers join it, just so that you are familiar with the process. Note that users might already be joined to a homegroup because Windows detects and will prompt you to join existing homegroups automatically during setup.

Understanding workgroups

In businesses where a little more control is required and a homegroup isn't the ideal configuration, a workgroup is used. A workgroup is a manual grouping of computers (almost any operating system will do, including Windows RT) that doesn't include an Active Directory domain controller, but still offers security options. A workgroup exists on a single network segment. Securing data here is a distributed concept similar to a homegroup; each user decides what to share, how to share it, and with whom to share. Note that Windows doesn't create a password for joining the workgroup, nothing is shared automatically by default (except possibly the Public folders), and users join the workgroup from the System Properties dialog box under the Computer Name tab (see Figure 1-13). Click Change in the System Properties dialog box, and then enter the workgroup name in the Computer Name/Domain Changes dialog box.

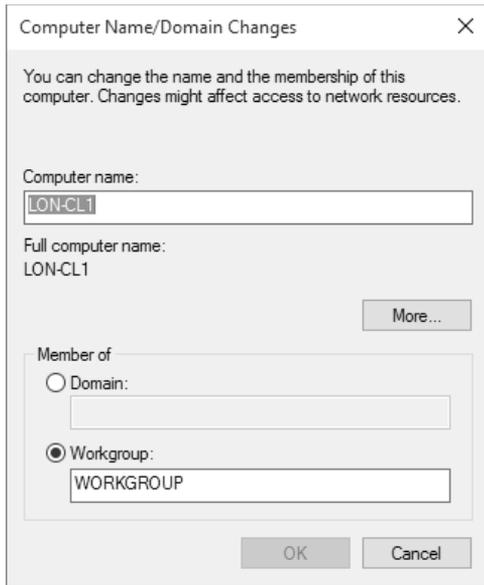

FIGURE 1-13 The Computer Name/Domain Changes dialog box

Because this section is about authorization, you need to consider that concept with regard to a workgroup. Users decide what to share, and then share it. The person who wants access to shared items must have an account on the sharing computer (or be given one). Accounts are stored in the Security Account Manager (SAM) database in the sharing computer. Because each computer maintains its own local database, users who need to access resources on multiple workgroup computers must be authenticated on each. The problem with this is that as the network grows, so does the amount of work required to maintain and manage these accounts.

Here is an overview of how authorization works:

1. The first time a user tries to access a shared resource, he or she is asked for a user name and password.
2. The user name and password that are entered must be from an approved account on the sharing computer and must be listed in the SAM database. The user can opt to have Windows remember the password for the next time.
3. The Local Security Authority (LSA) looks to the SAM database to see whether the account that was entered is valid.
4. If the account is valid, the user is granted access.
5. The same user who wants to access another shared resource on the same computer during the same session can do so without re-entering the password.
6. If this same user wants to access a shared resource on another computer in the workgroup, the process must be repeated.

UNDERSTANDING DOMAINS

Companies and enterprises configure networks as domains. You couldn't successfully manage 100 computers by using a homegroup or workgroup, so a domain is an obvious choice for enterprise networks.

Domains are configured with at least one AD DS domain controller that authenticates users centrally and secures network resources. These larger networks can contain additional servers that manage data storage, email, faxes, and printers; maintain database replications, and so on. Managing all resources as a whole is important to keeping everything secure and available for users, and enables a simpler management solution for administrators. A large enterprise can have more than one domain. When multiple domains exist, a Global Catalog is used to locate objects in other domains. Authentication in a domain is handled by AD DS, a database that contains objects, such as user accounts, computers, groups, and so on. In this case, a network administrator creates user accounts, almost always puts those accounts into groups, and then assigns the desired permissions to the group. This makes managing users simpler than trying to manage users one at a time, and it enables administrators to deal with newly hired or recently fired employees. The authentication process includes and uses the Kerberos v5 authentication protocol to identify the user or the host. The Kerberos Key Distribution Center (KDC) uses the domain-specific AD DS as its security account database. AD DS is required for default Kerberos implementations within the domain or forest. If you aren't familiar with Kerberos v5, the TechNet article "Kerberos Authentication Overview" at <http://technet.microsoft.com/en-us/library/hh831553.aspx> provides a good explanation of how this works and offers links to additional resources.

UNDERSTANDING COMPUTER AND USER AUTHENTICATION

The previous section discusses AD DS and authentication with regard to user accounts. Network administrators create these accounts, users input their account credentials to log on to the domain, and authentication is handled by the applicable AD DS server and Kerberos v5. Computers that join domains acquire a computer account automatically. Like user accounts, computer accounts are used to authenticate the computer to enable it to access network and domain resources. Each computer account must be unique. A user doesn't have to do anything to cause the computer to be authenticated. Note that computers have passwords that are automatically managed, and if a computer password on a client is out of sync with AD DS, then the computer can't authenticate.

Computer accounts are necessary for auditing, for control, and for grouping purposes. You can apply changes to computer accounts that affect whoever logs on to the computer, and not the individual users. For instance, you can force policies regarding the desktop appearance, how updates are applied, and so on, and those policies will affect the computer and anyone who uses it.

Administrators can manage computer accounts in the same way they can user accounts—by adding, deleting, resetting, and disabling them in the Active Directory Users And Computers snap-in.

UNDERSTANDING SECURE CHANNEL

When applications need network or Internet access, you have to ensure that the connection is secure. This is especially true if you are transmitting data over an untrusted network. You can use Transport Layer Security (TLS)/Secure Sockets Layer (SSL) security to authenticate servers and client computers, and then use that to encrypt messages between them. These two protocols are included in the Secure Channel set of security protocols. TLS and SSL aren't interchangeable and SSL is the predecessor to TLS, but both protect against tampering and eavesdropping.

Secure Channel can authenticate an identity as well as provide a secure and private connection to another host by using encryption. It's also called Schannel and is mostly used for applications that require secure HTTP communications. Schannel is a Security Support Provider (SSP), and the TLS/SSL protocol uses a client/server model that's based on certificate authentication. This means you need to also have a PKI configured and available.

MORE INFO DISCOVERING SECURE CHANNEL

You can learn more about this feature on TechNet at <http://technet.microsoft.com/en-us/library/hh831381.aspx>.

EXPLORING ACCOUNT POLICIES

The weakest link when protecting computers that use a password as part of the authentication process is most often the password itself. The password could be nonexistent (not likely, especially with the advent of the Microsoft account for stand-alone computers), too short, too simple, too predictable, or the user might simply never change it. Often, users create and use the same password for multiple user IDs. This is a secondary weak link. To protect authentication in both workgroups and domains, you can create local policies and Group Policy Objects (GPOs) defining how passwords should be created, how often they can or must be changed, and what happens when a user fails to log on after attempting a specific number of times that you set. You can configure account policies in the Local Security Policy for a stand-alone computer or for computers in a workgroup, and in Group Policy for domains. In Local Security Policy, Account Policies is listed first. Click Account Policies, and then click Account Lockout Policy to see the options.

You can configure three account lockout policies, and in most instances they must be configured together:

- **Account Lockout Duration** If you've configured an account lockout threshold and if that threshold is met, this setting defines how long (in minutes) the user will be locked out of the computer. A setting of 5 to 15 minutes is common.
- **Account Lockout Threshold** You need to configure this to use the other options. This setting defines how many times a user can try to log on to the computer and fail, before being locked out.

- **Reset Account Counter After** This setting defines the number of minutes that must pass after a failed logon attempt before the failed logon attempt counter is reset to zero. If an account lockout threshold is defined, this must be less than or equal to the number of minutes set there.

EXPLORING CREDENTIAL MANAGER

Using user names and passwords is a common way to authenticate users. Windows 10 includes Credential Manager to help manage and maintain those passwords. Credential Manager saves the credentials that users enter when they use their own computers to access network servers and resources on local networks (Windows credentials), and can be used to back up and restore them. When prompted, users have to check the box Remember My Credentials, or else the credentials won't be saved. Credential Manager also offers Credential Locker, which saves user names and passwords associated with websites and Windows apps (Web Credentials). It saves all of these in an area called the Windows Vault.

NOTE SAVING CREDENTIALS

Credentials are saved in encrypted folders on the computer under the user's profile. Applications that support this feature, such as web browsers and Windows apps, can automatically offer up the correct credentials to other computers and websites during the sign-in process.

If the user name or password has been changed since the last time it was saved and access is unsuccessful, the user is prompted to type the new credentials. When access to the resource or website is successful, Credential Manager and Credential Locker overwrite what was there.

The saved user names and passwords follow users when they move from one computer to another in a workgroup or homegroup, presuming they log on with their Microsoft accounts. However, this feature isn't enabled on domains for security reasons. You can open Credential Manager from Control Panel. Figure 1-14 shows Credential Manager.

Here are a few more points to understand about Credential Manager:

- You can program Windows Store apps to use Credential Locker.
- Credential roaming requires the Microsoft account for synchronization.
- Credential roaming is enabled by default on non-domain joined computers, and it is disabled on domain-joined computers.
- Credential Locker supports seamless sign in by using Windows Store apps that use Web Authentication Broker and remember passwords for services, such as Twitter and LinkedIn.

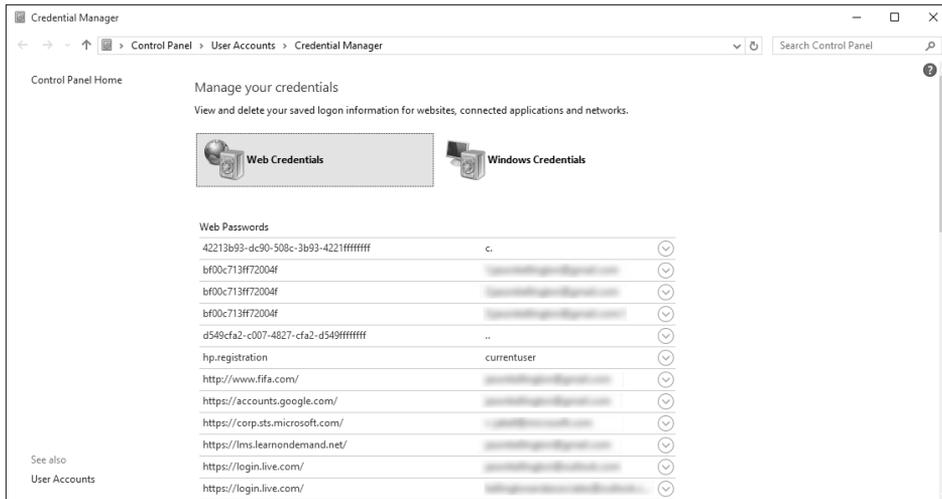

FIGURE 1-14 Credential Manager

Configure local accounts and Microsoft accounts

The Microsoft account enables users to sync settings to the cloud and to other computers that they log on to using that same Microsoft account. With a Microsoft account, users can also access their own cloud storage, called OneDrive. Windows 10 comes with the OneDrive app, which can be accessed from compatible applications, various web browsers, and File Explorer.

Users are prompted to create a Microsoft account when they set up their Windows 10-based computers. They can opt to do that, or they can decline and create a local account instead. A user might also create a local account if the computer can't access the Internet during setup (because they can't create or confirm the Microsoft account if no Internet access is available). Users generally opt to create a Microsoft account later, even if they start with a local account, because many apps are inaccessible if the user is logged on with a local account. Users also can't get apps from the Store without a Microsoft account.

After a Microsoft account is created, users don't need to be connected to the Internet to log on during subsequent sessions. The account information is cached locally. If an Internet connection isn't available, the last saved settings are also applied because they are also cached locally. You can switch from a local account to a Microsoft account from the Settings app.

A Microsoft account can be used in a domain, if it isn't restricted through Group Policy. If possible at your place of business, when connected, users will see the same desktop background, app settings, browser history, and so on that they see on their main computers at home (or in another office). Again, you can make the change through the Settings app. There, you'll opt to connect your Microsoft account and work through the setup process.

Configure Workplace Join

Personal devices have become part of the enterprise landscape, and if you don't already, at some point you need to be able to enable users to access network resources from them. This is how Workplace Join came about. Workplace Join enables users to have a single sign-on (SSO) experience and enables them to get to the resources they need. You can also manage and secure the devices. In Windows Server 2012 R2, you can use Workplace Join with Windows 8.1, Windows 10, and iOS devices.

Workplace Join uses the Device Registration Service (DRS), part of the Active Directory Federation Services (ADFS) role in Windows Server 2012 R2, to create a device object in AD DS and use a certificate to identify the device in the future. If you add Web Application Proxy, users can join your enterprise from any Internet-enabled location.

Various walkthrough guides are available on TechNet to help you use this technology to join devices. Here are two of those:

- "Walkthrough Guide: Workplace Join with a Windows Device": <https://technet.microsoft.com/en-us/library/dn280938.aspx>.
- "Walkthrough Guide: Workplace Join with an iOS Device": <https://technet.microsoft.com/en-us/library/dn280933.aspx>.

Configure Windows Hello

Windows Hello enables you to use a combination of optical recognition and fingerprint data to sign in to a Windows 10 computer, and authenticate to apps, enterprise content, and online authentication providers. Windows Hello is designed to be a user-friendly interface for configuring biometric authentication in Windows 10.

You can configure Windows Hello from the Settings app, in the Sign-in Options section of the Accounts page.

Thought experiment

Creating and configuring authentication solutions

In this thought experiment, apply what you've learned about this objective. You can find answers to these questions in the "Answers" section at the end of this chapter.

You've been asked to create and configure a multi-factor authentication solution that can be used to validate users in an enterprise domain. You've also been instructed to include digital certificates in that solution. Your client doesn't want to rely on a third party CA, and instead wants to use the Active Directory Certificate Services (AD CS) in Windows Server 2012 R2. Answer the following questions regarding this task.

1. The network currently doesn't include a PKI infrastructure. Will you need to add it?
2. Where will the client certificates you create be stored?
3. Where will the trusted root certificates you create be stored?
4. What command can you run, from a Run dialog box, on a client computer to view the certificates stored on that machine?

Objective summary

- Multi-factor authentication lets you further secure the authentication process with certificates, virtual smart cards, picture passwords, and biometrics, by requiring more than one method of authentication before access is granted.
- Different networks exist for different needs. Homegroups enable simple sharing for home networks; workgroups let you share and manage shared data in a non-domain setting; and domains are used by larger enterprises and include Active Directory Domain Services (AD DS) to secure and manage authentication.
- You can further secure authentication by including Secure Channel, account policies, credential caching, and Credential Manager to help control access and manage logon credentials.
- Local accounts are good for homegroups and workgroups, but now even those networks rely on Microsoft accounts for authorization management. Microsoft accounts can also be incorporated into domains to sync settings, such as desktop backgrounds.
- Workplace Join enables you to enroll and control mobile devices on your domain for the purpose of letting your users bring their own devices to work.
- Windows Hello enables configuration of facial and fingerprint recognition for use with the Windows 10 authentication process.

Objective review

Answer the following questions to test your knowledge of the information in this objective. You can find the answers to these questions and explanations of why each answer choice is correct or incorrect in the “Answers” section at the end of this chapter.

1. Which two of the following Windows PowerShell commands can you use to manage a CA database?
 - A. Backup-CARoleService
 - B. Restore-CARoleService
 - C. Backup-CACertStore
 - D. Restore-CACertStore
2. Which two of the following technologies offer authentication protection, confidentiality of the machine and its contents, private keys for security, and encrypted card information that can't be mined or removed?
 - A. Physical smart card
 - B. A compatible TPM chip
 - C. Virtual smart card
 - D. A biometric fingerprint reader
 - E. BitLocker Drive Encryption
3. You create a homegroup on one computer and join it from another. This process goes smoothly. However, when you try to access data shared with the homegroup from the second computer, you can't. What's most likely the problem?
 - A. You aren't connected to the network.
 - B. You aren't using BitLocker Drive Encryption.
 - C. The time is configured incorrectly on the second computer.
 - D. You aren't running a compatible version of Windows.
4. Which of the following network types is a distributed concept, in which users manage their own data sharing?
 - A. Workgroup
 - B. Homegroup
 - C. Domain
 - D. Workgroup or domain

5. You want to secure communications over an untrusted network for applications that need Internet access. You want to use TLS and SSL to achieve this. Which of the following technologies offers this? Must the solution include a PKI infrastructure?
- A. VPN
 - B. Remote Desktop Services
 - C. Microsoft Application Virtualization (App-V)
 - D. Secure Channel
6. You are trying to configure Group Policy to set an account lockout duration when users try and fail to authenticate their computers after a specific number of events. The options are grayed out. Why?
- A. You must first configure the policy Account Lockout Threshold.
 - B. You must first configure the policy Reset Account Counter After.
 - C. You are trying to configure the policy for a workgroup computer, but these policies are available only in domains.
 - D. You are in the Group Security Policy console, but need to be in the Group Policy Editor.
7. Can Credential Manager and Credential Locker be used to store passwords for Windows Store apps? Can Credential Manager and Credential Locker be used to store passwords saved for local network resources?
- A. Yes
 - B. No
 - C. Yes
 - D. No
8. You want to enable your domain users to access the same desktop background, app settings, browser history, and so on that they see on their main computers at home (or in another office). What should you do?
- A. A Microsoft account would be optimal, but can't be used in a domain.
 - B. Let the users associate their Microsoft accounts with their domain accounts.
 - C. Use Workplace Join.
 - D. Incorporate a Web Application Proxy server into your network.

Answers

This section contains the solutions to the thought experiments and answers to the objective review questions in this chapter.

Objective 1.1: Thought experiment

1. Office 365
2. Most likely using the cloud, with options that enable the user to sync that data even when they aren't online
3. Billing; Global; Password; Service; User Management

Objective 1.1: Review

1. **Correct answer:** A
 - A. **Correct:** Options to restrict the use of Microsoft accounts for a group of users in a domain are in the Group Policy Management Editor window. Expand Computer Configuration/ Policies/ Windows Settings/ Security Settings/ Local Policies/ Security Options.
 - B. **Incorrect:** The User Rights Assignment node doesn't provide options for restricting Microsoft accounts.
 - C. **Incorrect:** To restrict a group of users in an Active Directory domain, you need to access Group Policy, not Local Group Policy.
 - D. **Incorrect:** To restrict a group of users in an Active Directory domain, you need to access Group Policy, not Local Group Policy. Also, User Rights doesn't offer the options you need.
2. **Correct answer:** B
 - A. **Incorrect:** Users can do this from their local computers.
 - B. **Correct:** This is the correct answer; from their local computers, in the Settings app, from the Accounts page.
 - C. **Incorrect:** You can't connect a Microsoft account using Group Policy.
 - D. **Incorrect:** This is achieved in the Settings app, but not from the Personalization page.
3. **Correct answer:** D
 - A. **Incorrect:** Active Directory synchronization is one of the things you can manage in the Office 365 Admin Center, but others are correct here.
 - B. **Incorrect:** Valid, expired, and assigned licenses are some of the things you can manage in the Office 365 Admin Center, but others are correct here.
 - C. **Incorrect:** User passwords, including resetting, is one of the things you can manage in the Office 365 Admin Center, but others are correct here.

- D. **Correct:** All of the above can be configured in the Office 365 Admin Center.
 - E. **Incorrect:** All the answers are correct, not just B and C.
4. **Correct answer:** E
- A. **Incorrect:** DISM is only one of the correct options listed.
 - B. **Incorrect:** Windows PowerShell is only one of the correct options listed.
 - C. **Incorrect:** Configuration Manager is only one of the correct options listed.
 - D. **Incorrect:** Windows Intune is only one of the correct options listed.
 - E. **Correct:** All of the above
 - F. **Incorrect:** "Only C and D" isn't correct because A and B are correct also.
5. **Correct answer:** B
- A. **Incorrect:** Special Group Policies are required.
 - B. **Correct:** Allow All Trusted Apps To Install is the required Group Policy setting that must be enabled.
 - C. **Incorrect:** Allow Development Of Windows Store Apps isn't the correct Group Policy setting to enable.
 - D. **Incorrect:** You should not block Microsoft accounts; you need to enable the Group Policy setting listed for answer B.
6. **Correct answer:** B
- A. **Incorrect:** You cannot make sideloaded apps mandatory and force their installation on clients by applying the applicable settings in Windows Intune.
 - B. **Correct:** This statement is false.
7. **Correct answer:** A
- A. **Correct:** You deep link apps to make Windows Store apps available through the company portal.
 - B. **Incorrect:** You do not use deep linking to force the installation of apps on Windows 10 computers.
 - C. **Incorrect:** You don't use deep linking to add LOB apps to the Windows Store. It's used to make Windows Store apps available through the company portal.
 - D. **Incorrect:** "None of the above" isn't correct. A is correct.

Objective 1.2: Thought experiment

1. Yes. AC CS in Windows Server 2012 requires an existing PKI infrastructure.
2. Client certificates are stored in the Personal certificate store for the applicable user account on the client computer.
3. Trusted root certificates are stored in the Trusted Root Certification Authorities store on the client computer.
4. Certmgr.msc can be used to open the Certmgr window.

Objective 1.2: Review

1. **Correct answers:** A and B
 - A. **Correct:** Backup-CARoleService is the correct command for backing up the CA database.
 - B. **Correct:** Restore-CARoleService is the correct command for restoring the CA database.
 - C. **Incorrect:** This isn't a valid Windows PowerShell command.
 - D. **Incorrect:** This isn't a valid Windows PowerShell command.
2. **Correct answers:** B and C
 - A. **Incorrect:** A physical smart card can be removed.
 - B. **Correct:** The solution here requires a compatible TPM chip and a virtual smart card.
 - C. **Correct:** The solution here requires a compatible TPM chip and a virtual smart card.
 - D. **Incorrect:** A biometric fingerprint reader doesn't offer private keys for security.
 - E. **Incorrect:** BitLocker Drive Encryption is used to protect data on the drive and isn't for authentication purposes.
3. **Correct answer:** C
 - A. **Incorrect:** If you've joined the homegroup, you are connected to the network.
 - B. **Incorrect:** BitLocker Drive Encryption isn't required to join a homegroup.
 - C. **Correct:** The time is configured incorrectly on the second computer.
 - D. **Incorrect:** If you have joined the homegroup, you are running a compatible version of Windows.
4. **Correct answers:** A and B
 - A. **Correct:** A workgroup uses a distributed method for sharing data.
 - B. **Correct:** A homegroup uses a distributed method for sharing data.
 - C. **Incorrect:** A domain uses a centralized method of sharing and managing data and uses AD DS for authentication and user access.
 - D. **Incorrect:** Although a workgroup is a distributed sharing method, a domain isn't.

- 5. Correct answer: D**
- A. Incorrect:** A VPN enables users to access your local network when they are away from the office. VPNs might use PPTP or L2TP to secure the connection.
 - B. Incorrect:** Remote Desktop Services enables users to access session-based desktops, virtual machine-based desktops, or applications from both within a network and from the Internet.
 - C. Incorrect:** App-V enables the application to run in a virtualized environment without having to install or configure it on the local machine.
 - D. Correct:** Secure Channel is a Security Support Provider (SSP), and the TLS/SSL protocol uses a client/server model that's based on certificate authentication. It does require a PKI infrastructure.
- 6. Correct answer: A**
- A. Correct:** You need to first configure the policy Account Lockout Threshold to state how many times a user can try to authenticate before additional measures are taken.
 - B. Incorrect:** The policy Reset Account Counter After is optional.
 - C. Incorrect:** These policies are available in both workgroups and domains.
 - D. Incorrect:** The Group Security Policy console is the appropriate place to create these policies.
- 7. Correct answer: C**
- A. Incorrect:** Credential Manager can store Windows Store passwords as well as local ones.
 - B. Incorrect:** Credential Manager can store Windows Store passwords as well as those input for local resources.
 - C. Correct:** Credential Manager can store Windows Store passwords as well as passwords for local resources.
 - D. Incorrect:** Credential Manager can store both Windows Store passwords and local user passwords.
- 8. Correct answer: B**
- A. Incorrect:** A Microsoft account can be used in a domain if it isn't restricted through Group Policy.
 - B. Correct:** Enable the user to associate their own Microsoft account to achieve this.
 - C. Incorrect:** Workplace Join enables users to connect to your domain with their own personal devices.
 - D. Incorrect:** If you add Web Application Proxy, users can join your enterprise from any Internet-enabled location by using a device you've allowed using Workplace Join.

About the authors

ANDREW BETTANY is a Microsoft Most Valuable Professional (MVP), recognized for his Windows expertise, and author of several publications including Windows exam certification prep and Microsoft official training materials. As leader of the IT Academy at the University of York, UK and Microsoft Certified Trainer, Andrew delivers learning and consultancy to businesses on a number of technical areas including Windows deployment and troubleshooting. He

has created and manages the "IT Masterclasses" series of short intensive technical courses, www.itmasterclasses.com and is passionate about helping others learn technology. He is a frequent speaker and proctor at TechEd and Ignite conferences worldwide. In 2011 and 2013 he delivered classes in earthquake-hit Haiti to help the community rebuild their technology skills. Very active on social media, having co-founded Queuedit.com, as Social Media Management tool, Andrew can be found on LinkedIn, Facebook, and Twitter. He lives in a village just outside of the beautiful city of York in Yorkshire (UK)

JASON KELLINGTON MCT, MCSE, MCITP, MCTS, is a consultant, trainer, and author living in beautiful, cold northern Canada with his wife and two boys. Jason has spent time as an engineer, developer, administrator, and educator during his 15+ years in IT. His consulting and training practice specialize in enterprise infrastructure deployment as well as data management and business intelligence. He has assisted in the development of

several projects with Microsoft Press and Microsoft Learning.
