Because a typical disc can hold a maximum of 74 minutes of data, and each second contains 75 blocks of 2,048 bytes each, you can calculate the absolute maximum storage capacity of a CD-ROM at 681,984,000 bytes—rounded as 682MB (megabytes) or 650MiB (mebibytes). Table 13.3 shows the structure and layout of each sector on a CD-ROM on which data is stored.

Table 13.3 CD-ROM Sector Information and Capacity

Each Data Sector (Mode 1):	74-Minute	80-Minute
Q+P parity bytes	784	784
Subcode bytes	98	98
Sync bytes	12	12
Header bytes	8	8
ECC/EDC bytes	284	284
Data bytes	2,048	2,048
Bytes/sector RAW (unencoded)	3,234	3,234

Table 13.3 Continued

Each Data Sector (Mode 1):	74-Minute	80-Minute
Actual CD-ROM Data Capacity:		
B	681,984,000	737,280,000
KiB	666,000	720,000
KB	681,984	737,280
MiB	650.39	703.13
MB	681.98	737.28

B = Byte (8 bits)
KB = Kilobyte (1,000 bytes)
KiB = Kibibyte (1,024 bytes)
MB = Megabyte (1,000,000 bytes)
MiB = Mebibyte (1,048,576 bytes)
ECC = Error correction code
EDC = Error detection code

This information assumes the data is stored in Mode 1 format, which is used on virtually all data discs. You can learn more about the Mode 1/Mode 2 formats in the section on the Yellow Book and XA standards later in this chapter.

With data sectors, you can see that out of 3,234 actual bytes per sector, only 2,048 are actual CD-ROM user data. Most of the 1,186 other bytes are used for the intensive error detection and correction schemes to ensure error-free performance.

Data Encoding on the Disc

The final part of how data is actually written to the CD is very interesting. After all 98 frames are composed for a sector (whether audio or data), the information is then run through a final encoding process called EFM (eight to fourteen modulation). This scheme takes each byte (8 bits) and converts it into a 14-bit value for storage. The 14-bit conversion codes are designed so that there are never less than 2 or more than 10 adjacent 0 bits. This is a form of Run Length Limited (RLL) encoding called RLL 2,10 (RLL x,y where x = the minimum and y = the maximum run of 0s). This is designed to prevent long strings of 0s, which could more easily be misread, as well as to limit the minimum and maximum frequency of transitions actually placed on the recording media. With as few as 2 or as many as 10 0 bits separating 1 bits in the recording, the minimum distance between 1s is three bit time intervals (usually referred to as 3T) and the maximum spacing between 1s is 11 time intervals (11T).

Because some of the EFM codes start and end with a 1 or more than five 0s, three additional bits called *merge bits* are added between each 14-bit EFM value written to the disc. The merge bits usually are 0s but might contain a 1 if necessary to break a long string of adjacent 0s formed by the adjacent 14-bit EFM values. In addition to the now 17-bits created for each byte (EFM plus merge bits), a 24-bit sync word (plus 3 more merge bits) is added to the beginning of each frame. This results in a total of 588 bits (73.5 bytes) actually being stored on the disc for each frame. Multiply this for 98 frames per sector and you have 7,203 bytes actually being stored on the disc to represent each sector. A 74-minute disc, therefore, really has something like 2.4GB of actual data being written, which after being fully decoded and stripped of error correcting codes and other information, results in about 682MB (650MiB) of actual user data.

The calculations for EFM encoded frames and sectors are shown in Table 13.4.

Table 13.4 EFM Encoded Data Calculations

EFM-Encoded Frames:	74-Minute	80-Minute
Sync word bits	24	24
Subcode bits	14	14
Data bits	336	336
Q+P parity bits	112	112
Merge bits	102	102
EFM bits per frame	588	588
EFM Encoded Sectors:		
EFM bits per sector	57,624	57,624
EFM bytes per sector	7,203	7,203
Total EFM data on disc (MB)	2,399	2,593

B = Byte (8 bits)
KB = Kilobyte (1,000 bytes)
KiB = Kibibyte (1,024 bytes)
MB = Megabyte (1,000,000 bytes)
MiB = Mebibyte (1,048,576 bytes)
EFM = Eight to fourteen modulation

To put this into perspective, see Table 13.5 for an example of how familiar data would actually be encoded when written to a CD. As an example, I'll use the letters "N" and "O" as they would be written on the disk. Table 13.5 shows the digitally encoded representations of these letters.

Table 13.5 EFM Data Encoding on a CD

Character	"N"	"O"
ASCII decimal code	78	79
ASCII hexadecimal code	4E	4F
ASCII binary code	01001110	01001111
EFM code	00010001000100	00100001000100

ASCII = American Standard Code for Information Interchange
EFM = Eight to fourteen modulation

Figure 13.5 shows how the encoded data would actually appear as pits and lands stamped into a CD.

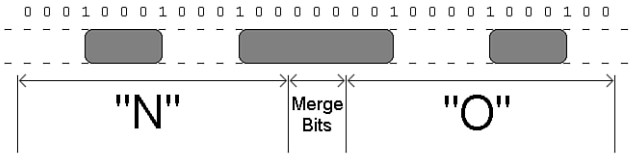

Figure 13.5 EFM data physically represented as pits and lands on a CD.

The edges of the pits are translated into the binary 1 bits. As you can see, each 14-bit grouping is used to represent a byte of actual EFM encoded data on the disc, and each 14-bit EFM code is separated by three merge bits (all 0s in this example). The three pits produced by this example are 4T (4 transitions), 8T, and 4T long. The string of 1s and 0s on the top of the figure represent how the actual data would be read; note that a 1 is read wherever a pit-to-land transition occurs. It is interesting to note that this drawing is actually to scale, meaning the pits (raised bumps) would be about that long and wide relative to each other. If you could use a microscope to view the disc, this is what the word "NO" would look like as actually recorded.

CD Drive Speed

When a drive seeks out a specific data sector or musical track on the disc, it looks up the address of the data from a table of contents contained in the lead-in area and positions itself near the beginning of this data across the spiral, waiting for the right string of bits to flow past the laser beam.

Because CDs originally were designed to record audio, the speed at which the drive reads the data had to be constant. To maintain this constant flow, CD-ROM data is recorded using a technique called *constant linear velocity (CLV)*. This means that the track (and thus the data) is always moving past the read laser at the same speed, which originally was defined as 1.3 meters per second. Because the track is a spiral that is wound more tightly near the center of the disc, the disc must spin at various rates to maintain the same track linear speed. In other words, to maintain a CLV, the disk must spin more quickly when reading the inner track area than when reading the outer track area. The speed of rotation in a 1x drive (1.3 meters per second is considered 1x speed) varies from 540rpm when reading the start (inner part) of the track down to 212rpm when reading the end (outer part) of the track.

In the quest for greater performance, drive manufacturers began increasing the speeds of their drives by making them spin more quickly. A drive that spins twice as fast was called a 2x drive, one that spins four times faster was called 4x, and so on. This was fine until about the 12x point, where drives were spinning discs at rates from 2,568rpm to 5,959rpm to maintain a constant data rate. At higher speeds than this, it became difficult to build motors that could change speeds (spin up or down) as quickly as necessary when data was read from different parts of the disc. Because of this, most drives rated faster than 12x spin the disc at a fixed rotational, rather than linear speed. This is termed *constant angular velocity (CAV)* because the angular velocity (or rotational speed) remains a constant.

CAV drives are also generally quieter than CLV drives because the motors don't have to try to accelerate or decelerate as quickly. A drive (such as most rewritables) that combines CLV and CAV technologies is referred to as *Partial-CAV* or *P-CAV*. Most writable drives, for example, function in CLV mode when burning the disc and in CAV mode when reading. Table 13.6 compares CLV and CAV.

Table 13.6 CLV Versus CAV Technology Quick Reference

	CLV (Constant Linear Velocity)	CAV (Constant Angular Velocity)
Speed of CD rotation:	Varies with data position on CD—faster on inner tracks than on outer tracks	Constant
Data transfer rate:	Constant	Varies with data position on CD— faster on outer tracks than on inner tracks
Average noise level:	Higher	Lower

CD-ROM drives have been available in speeds from 1x up to 56x and beyond. Most nonrewritable drives up to 12x were CLV; most drives from 16x and up are CAV. With CAV drives, the disc spins at a constant speed, so track data moves past the read laser at various speeds, depending on where the data is physically located on the CD (near the inner or outer part of the track). This also means that CAV drives read the data at the outer edge (end) of the disk more quickly than data near the center (beginning). This allows for some misleading advertising. For example, a 12x CLV drive reads data at 1.84MB/sec no matter where that data is on the disc. On the other hand, a 16x CAV drive reads data at speeds up to 16x (2.46MB/sec) on the outer part of the disc, but it also reads at a much lower speed of only 6.9x (1.06MB/sec) when reading the inner part of the disc (that is the part they don't tell you). On average, this would be only 11.5x, or about 1.76MB/sec. In fact, the average is actually overly optimistic because discs are read from the inside (slower part) out, and an average would relate only to reading completely full discs. The real-world average could be much less than that.

What this all means is that on average the 12x CLV drive would be noticeably faster than the 16x drive, and faster than even a 20x drive! Remember that all advertised speeds on CAV drives are only the maximum transfer speed the drive can achieve, and it can achieve that only when reading the very outer (end) part of the disc.

Table 13.7 contains data showing CD-ROM drive speeds along with transfer rates and other interesting data.

Vibration problems can cause high-speed drives to drop to lower speeds to enable reliable reading of CD-ROMs. Your CD-ROM can become unbalanced, for example, if you apply a small paper label to its surface to identify the CD or affix its serial number or code for easy reinstallation. For this reason, many of the faster CD and DVD drives come with autobalancing or vibration-control mechanisms to overcome these problems. The only drawback is that if they detect a vibration, they slow down the disc, thereby reducing the transfer rate performance.

TrueX Technology

Extremely fast drives are usually CAV drives due to limitations in the rotational speeds achievable. Even with CAV, a 56x rated drive would rotate at nearly 12,000rpm and the data would be moving at nearly 163 miles per hour past the laser on the outer part of the track! Rather than try to spin discs even faster for higher reading speeds, a company called Zen Research has developed a technology called TrueX (also called Multibeam), which uses multiple laser beams to achieve constant high transfer rates (reading speeds) without the limitations of CAV. Currently, this technology is licensed by several companies, although Kenwood has been the primary promoter and manufacturer of TrueX drives and has released drives in 42x, 52x, 62x, and 72x models, which have benchmarked as the fastest CD-ROM drives available.

Table 13.7 CD-ROM Drive Speeds and Transfer Rates

Column 1	Column 2	Column 3	Column 4	Column 5	Column 6
Advertised CD-ROM Speed (Max. if CAV)	Time to Read 74-minute CD if CLV	Time to Read 80-minute CD if CLV	Transfer Rate (Bytes/sec) (Max. if CAV)	Actual CD-ROM Speed Minimum if CAV	Minimum Transfer Rate if CAV (Bytes/sec)
1x	74.0	80.0	153,600	0.4x	61,440
2x	37.0	40.0	307,200	0.9x	138,240
4x	18.5	20.0	614,400	1.7x	261,120
6x	12.3	13.3	921,600	2.6x	399,360
8x	9.3	10.0	1,228,800	3.4x	522,240
10x	7.4	8.0	1,536,000	4.3x	660,480
12x	6.2	6.7	1,843,200	5.2x	798,720
16x	4.6	5.0	2,457,600	6.9x	1,059,840
20x	3.7	4.0	3,072,000	8.6x	1,320,960
24x	3.1	3.3	3,686,400	10.3x	1,582,080
32x	2.3	2.5	4,915,200	13.8x	2,119,680
40x	1.9	2.0	6,144,000	17.2x	2,641,920
48x	1.5	1.7	7,372,800	20.7x	3,179,520
50x	1.5	1.6	7,680,000	21.6x	3,317,760
52x	1.4	1.5	7,987,200	22.4x	3,440,640
56x	1.3	1.4	8,601,600	24.1x	3,701,760

Each of the columns in Table 13.7 are explained here:

Column 1 indicates the advertised drive speed. This is a constant speed if the drive is CLV (most 12x and lower) or a maximum speed only if CAV.

Columns 2 and 3 indicate how long it would take to read a full disc if the drive was CLV. For CAV drives, those figures would be longer because the average read speed is less than the advertised speed. The fourth column indicates the data transfer rate, which for CAV drives would be a maximum figure only when reading the end of a disc.

Columns 3–6 indicate the actual minimum "x" speed for CAV drives, along with the minimum transfer speed (when reading the start of any disc) and an optimistic average speed (true only when reading a full disc; otherwise, it would be even lower) in both "x" and byte-per-second formats.

TrueX drives use a diffraction grating to split a single beam into seven beams reading seven tracks simultaneously to improve the transfer rate while maintaining a slower rotational speed that reduces noise and vibration. Drives with TrueX technology are among the fastest CD-ROM drives on the market, capable of sustaining near-CLV performance at high reading speeds consistently no matter where they are reading on the disc.

The net effect is that the reading speed is consistently higher than equivelant speed CAV drives, and yet the TrueX drives spin at a slower rotational speed. For example, a 52x CAV drive performs from about 22x at the start of a disc to 52x at the end, whereas a 52x TrueX drive performs at about 45x at the start of a disc to 52x at the end. This results in a much higher average performance level that is nearly consistent with CLV drives.

Column 7	Column 8	Column 9	Column 10	Column 11	Column 12
Average CD-ROM Speed if CAV	Average Transfer Rate if CAV (Bytes/sec)	Maximum Linear Speed (m/sec)	Maximum Linear Speed (mph)	Rotational Speed Min. if CLV Max. if CAV (rpm)	Rotational Speed Max. if CLV (rpm)
0.7x	107,520	1.3	2.9	214	497
1.5x	222,720	2.6	5.8	428	993
2.9x	437,760	5.2	11.6	856	1,986
4.3x	660,480	7.8	17.4	1,284	2,979
5.7x	875,520	10.4	23.3	1,712	3,973
7.2x	1,098,240	13.0	29.1	2,140	4,966
8.6x	1,320,960	15.6	34.9	2,568	5,959
11.5x	1,758,720	20.8	46.5	3,425	7,945
14.3x	2,196,480	26.0	58.2	4,281	9,931
17.2x	2,634,240	31.2	69.8	5,137	11,918
22.9x	3,517,440	41.6	93.1	6,849	15,890
28.6x	4,392,960	52.0	116.3	8,561	19,863
34.4x	5,276,160	62.4	139.6	10,274	23,835
35.8x	5,498,880	65.0	145.4	10,702	24,828
37.2x	5,713,920	67.6	151.2	11,130	25,821
40.1x	6,151,680	72.8	162.8	11,986	27,808

Columns 7–8 indicate the maximum linear speeds the drive will attain, in both meters per second and miles per hour. CLV drives maintain those speeds everywhere on the disc, whereas CAV drives reach those speeds only on the outer part of a disc.

Columns 9–12 indicate the rotational speeds of a drive. The first of those shows how fast the disc spins when reading the start of a disc; this would apply to either CAV or CLV drives. For CAV drives, that figure is constant no matter where on the disc it is reading. The last column shows the maximum rotational speed if the drive were a CLV type. Because most drives over 12x are CAV, those figures are mostly theoretical for the 16x and faster drives.

Another drawback is that there have been some compatibility problems with different types of media, causing most drive manufacturers to prefer more conventional means of increasing speeds. Instead of TrueX, most are now moving to Z-CLV (zoned CLV) or P-CAV (partial CAV) designs, which help to increase average performance while keeping rotational speeds under control.

Compact Disc and Drive Formats

After Philips and Sony created the Red Book CD-DA format discussed earlier in the chapter, they began work on other format standards that would allow CDs to store computer files, data, and even video and photos. These standards control how the data is formatted so that the drive can read it, and additional file format standards can then control how the software and drivers on your PC can be

designed to understand and interpret the data properly. Note that the physical format and storage of data on the disc as defined in the Red Book was adopted by all subsequent CD standards. This refers to the encoding and basic levels of error correction provided by CD-DA discs. The other "books" specify primarily how the 2,352 bytes in each sector are to be handled, what type of data can be stored, how it should be formatted, and more.

All the official CD standard books and related documents can be purchased from Philips for $100–$150 each. See the Philips licensing site at `http://www.licensing.philips.com` for more information.

Table 13.8 describes the various standard CD formats, which are discussed in more detail in the following sections.

Table 13.8 Compact Disc Formats

Format	Name	Introduced	Notes
Red Book	CD-DA (compact disc digital audio)	1980 - by Philips and Sony	• The original CD audio standard on which all subsequent CD standards are based.
Yellow Book	CD-ROM (compact disc read-only memory)	1983 - by Philips and Sony	• Specifies additional ECC and EDC for data in several sector formats, including Mode 1 and Mode 2.
Green Book	CD-i (compact disc-interactive)	1986 - by Philips and Sony	• Specifies an interactive audio/video standard for nonPC-dedicated player hardware (now mostly obsolete) and discs used for interactive presentations. • Defines Mode 2, Form 1 and Mode 2, Form 2 sector formats along with interleaved MPEG-1 video and ADPCM audio.
CD-ROM XA	CD-ROM XA (extended architecture)	1989 - by Philips, Sony, and Microsoft	• Combines Yellow Book and CD-i to bring CD-i audio and video capabilities to PCs.
Orange Book	CD-R (recordable) and CD-RW (rewritable)	1989 - by Philips and Sony (Part I/II); 1996 - by Philips and Sony (Part III)	• Defines single session, multisession, and packet writing on recordable discs. • Part I—CD-MO (magneto-optical, withdrawn). • Part II—CD-R (recordable). • Part III—CD- RW (rewritable).
Photo-CD	CD-P	1990 - by Philips and Kodak	• Combines CD-ROM XA with CD-R multisession capability in a standard for photo storage on CD-R discs.
White Book	Video CD	1993 - by Philips, JVC, Matsushita, and Sony	• Based on CD-i and CD-ROM XA. It stores up to 74 minutes of MPEG-1 video and ADPCM digital audio data.
Blue Book	CD EXTRA (formerly CD-Plus or enhanced music)	1995 - by Philips and Sony	• Multisession format for stamped discs; used by musical artists to incorporate videos, liner notes, and other information on audio CDs.

Red Book—CD-DA

The Red Book introduced by Philips and Sony in 1980 is the father of all compact-disc specifications because all other "books" or formats are based on the original CD-DA Red Book format. The Red Book specification includes the main parameters, audio specification, disc specification, optical stylus, modulation system, error correction system, and control and display system. The latest revision of the Red Book is dated May 1999.

For more information on the original Red Book format, see the section "CDs: A Brief History" earlier in this chapter.

Yellow Book—CD-ROM

The Yellow Book was first published by Philips, Sony, and Microsoft in 1983 and has been revised and amended several times since. The Yellow Book standard took the physical format of the original CD-DA, or Red Book, standard and added another layer of error detection and correction to enable data to be stored reliably. It also added additional synchronization and header information to enable sectors to be more accurately located. Yellow Book specifies two types of sectoring—called Mode 1 (with error correction) and Mode 2—which offer different levels of error detection and correction schemes. Some data (computer files, for example) can't tolerate errors. However, other data, such as a video image or sound, can tolerate minor errors. By using a mode with less error correction information, more data can be stored, but with the possibility of uncorrected errors.

In 1989, the Yellow Book was issued as an international standard by the ISO as *ISO/IEC 10149, Data Interchange on Read-Only 120mm Optical Discs (CD-ROM)*. The latest version of the Yellow Book is dated May 1999.

Green Book—CD-i

The Green Book was published by Philips and Sony in 1986. CD-i is much more than just a disc format; instead it is a complete specification for an entire interactive system consisting of custom hardware (players) designed to be connected to a television, software designed to deliver video and audio together with user interactivity in real time, and the media and format. A CD-i player is actually a dedicated computer usually running a variant on the Motorola 68000 processor line, as well as a customized version of the Microware OS/9 Real Time Operating System.

CD-i enables both audio and video to share a disc and enables the information to be interleaved so as to maintain synchronization between the pictures and sounds. To fit both audio and video in the same space originally designed for just audio, compression was performed. The video was compressed using the Moving Picture Experts Group-1 (MPEG-1) compression standard, whereas the audio was compressed with adaptive differential pulse code modulation (ADPCM). ADPCM is an audio encoding algorithm that takes about half the space for the same quality of standard PCM, and even less if quality is reduced by lowering the sampling rate or bits per sample. Using ADPCM, up to 8 hours of stereo or 16 hours of mono sound can fit on one CD. The "differential" part of ADPCM refers to the fact that it records the differences between one signal and the next (using only 4-bit numbers), which reduces the total amount of data involved. ADPCM audio can be interleaved with video in CD-i (and CD-ROM XA) applications.

The Yellow Book defines two CD-ROM sector structures, called Mode 1 and Mode 2. The Green Book (CD-i) refines the Mode 2 sector definition by adding two forms, called Mode 2, Form 1 and Mode 2, Form 2. The Mode 2, Form 1 sector definition uses ECC and allows for 2,048 bytes of data storage like the Yellow Book Mode 1 sectors, but it rearranged things slightly to use the 8 formerly unused (blank or 0) bytes as a subheader containing additional information about the sector. The Mode 2, Form 2 definition drops the ECC and allows 2,324 bytes for data. Without the ECC, only video or audio

information should be stored in Form 2 sectors because that type of information can tolerate minor errors.

Media or titles available for CD-i include all manner of educational and training applications, games, encyclopedias, karaoke, and movies. Note that CD-i discs can't be "played" on PCs. In fact, because the files are in an OS/9 file format, your PC won't even be capable of seeing the files on the disc! Even so, drivers have been written that can be installed and will enable viewing the files, and one enterprising individual has even written a CD-i emulator called CD-iCE that emulates a CD-i player and thus enables CD-i applications to be run. You can find out more about the CD-iCE emulator at `http://www.emuhq.com/cdi`.

Today, the CD-i format is largely obsolete. The last revision of the standard was produced in May 1994. Philips sold off its entire consumer CD-i catalogue to Infogrames Multimedia in 1998, which now owns the rights for virtually all consumer CD-i titles ever produced. Philips made a final run of CD-i players in 1999, and it is doubtful any new ones will ever be produced. The legacy of CD-i lives on in the other formats that use specifications originally devised for CD-i, such as the Mode 2, Form 1 and Form 2 sector structures found in CD-XA and the MPEG-1 video format later used in the White Book (CD-Video).

CD-ROM XA

CD-ROM XA originally was defined in 1989 by Philips, Sony, and Microsoft as a supplement to the Yellow Book. CD-ROM XA brings some of the features originally defined in the Green Book (CD-i) to the Yellow Book (CD-ROM) standard, especially for multimedia use. CD-ROM XA adds three main features to the Yellow Book standard. The first consists of the CD-i-enhanced sector definitions (called forms) for the Mode 2 sectors; the second is a capability called interleaving (mixing audio and video information); and the third is ADPCM for compressed audio. The latest version of the CD-ROM XA standard was released in May 1991.

Interleaving

CD-ROM XA drives can employ a technique known as *interleaving*. The specification calls for the capability to encode on disc whether the data directly following an identification mark is graphics, sound, or text. Graphics can include standard graphics pictures, animation, or full-motion video. In addition, these blocks can be interleaved, or interspersed, with each other. For example, a frame of video can start a track followed by a segment of audio, which would accompany the video, followed by yet another frame of video. The drive picks up the audio and video sequentially, buffering the information in memory and then sending it along to the PC for synchronization.

In short, the data is read off the disc in alternating pieces and then synchronized at playback so that the result is a simultaneous presentation of the data. Without interleaving, the drive would have to read and buffer the entire video track before it could read the audio track and synchronize the two for playback.

Sector Modes and Forms

Mode 1 is the standard Yellow Book CD sector format with ECC and EDC to enable error-free operation. Each Mode 1 sector is broken down as shown in Tables 13.9 and 13.10.

Table 13.9 Yellow Book Mode 1 Sector Format Breakdown

Yellow Book (CD-ROM) sectors (Mode 1):	
Q+P parity bytes	784
Subcode bytes	98
Sync bytes	12
Header bytes	4
Data bytes	2,048
EDC bytes	4
Blank (0) bytes	8
ECC bytes	276
Bytes/sector RAW (unencoded)	3,234

Table 13.10 Yellow Book (CD-ROM) Mode 1 Sector Format

Sync	Header	User Data	EDC	Blank	ECC
12	4	2,048	4	8	276

In the original Yellow Book, Mode 2 was defined as a sector without any ECC or EDC. Unfortunately, Mode 1 (which had ECC and EDC) couldn't be mixed with Mode 2 sectors on the same track (program or song). To enable data with and without error detection and correction in a single track, new sector format subsets for Mode 2 sectors were added in the Green Book (CD-i) and subsequently adopted in the CD-ROM XA extensions. This enabled information that would not tolerate errors (such as programs or computer data) to be interleaved or mixed within the same track with information that would tolerate errors (such as audio or video data). These variations on Mode 2 include Form 1 and Form 2 sectors. Each Mode 2, Form 1 sector is broken down as shown in Tables 13.11, 13.12, 13.13, and 13.14.

Table 13.11 Green Book Mode 1 Sector Format Breakdown

Green Book/CD-ROM XA sectors (Mode 2, Form 1):	
Q+P parity bytes	784
Subcode bytes	98
Sync bytes	12
Header bytes	4
Subheader bytes	8
Data bytes	2,048
EDC bytes	4
ECC bytes	276
Bytes/sector RAW (unencoded)	3,234

Table 13.12 Green Book/CD-ROM XA (Yellow Book Extensions) Mode 2, Form 1 Sector Format

Sync	Header	Subheader	User Data	EDC	ECC
12	4	8	2,048 bytes	4	276

Table 13.13 Green Book Mode 2 Sector Format Breakdown

Green Book/CD-ROM XA sectors (Mode 2, Form 2):	
Q+P parity bytes	784
Subcode bytes	98
Sync bytes	12
Header bytes	4
Subheader bytes	8
Data bytes	2,324
EDC bytes	4
Bytes/sector RAW (unencoded)	3,234

Table 13.14 Green Book/CD-ROM XA (Yellow Book Extensions) Mode 2, Form 2 Sector Format

Sync	Header	Subheader	User Data	EDC
12	4	8	2,324 bytes	4

Both Mode 2 sector formats add a subheader field that identifies the type of information (such as audio or video) carried in the user data field. The Form 2 sector lacks the ECC of the Form 1 sector and increases the size of the user data field instead. This type of sector is for storing audio or video data that can tolerate errors.

Because they don't use any third-level error correction, CD-ROMs that use the Mode 2, Form 2 sector format (such as MPEG video CDs) can hold more user information than other CD-ROM types in the same number of sectors and as a result also have a higher data transfer rate of 174.3KB/sec instead of the standard 153.6KB/sec. Note that Form 2 sectors are never used to store data or program files because errors can't be tolerated in that type of information. In that case, the Mode 2, Form 1 sector format would be used.

For a drive to be truly XA compatible, the audio data written in Form 2 sectors on the disc as audio must be ADPCM audio—specially compressed and encoded audio. This requires that the drive or the SCSI controller have a signal processor chip that can decompress the audio during the synchronization process.

Some earlier drives were called XA-ready, which meant they were capable of Mode 2, Form 1 and Form 2 reading but did not incorporate the ADPCM chip. This is not a significant shortcoming, however, because only certain multimedia titles use the ADPM encoding (with interleaved audio and

video). The main benefit XA brought to the table was the additional sector modes and forms taken from the Green Book.

Orange Book

The Orange Book defines the standards for recordable CDs and originally was announced in 1989 by Philips and Sony. The Orange Book comes in three parts: Part I describes a format called CD-MO (magneto-optical), which was to be a rewritable format but was withdrawn before any products really came to market; Part II (1989) describes CD-R; and Part III (1996) describes CD-RW. Note that originally CD-R was referred to as CD-WO (write-once), and CD-RW originally was called CD-E (erasable).

The Orange Book Part II CD-R design is known as a WORM (write once read mostly) format. After a portion of a CD-R disc is recorded, it can't be overwritten or reused. Recorded CD-R discs are Red Book and Yellow Book compatible, which means they are readable on conventional CD-DA or CD-ROM drives. The CD-R definition in the Orange Book Part II is divided into two volumes. Volume 1 defines recording speeds of 1x, 2x, and 4x the standard CD speed; the last revision, dated December 1998, is 3.1. Volume 2 defines recording speeds up to 48x the standard CD speed. The latest version released, 1.2, is dated April 2002.

The Orange Book Part III describes CD-RW. As the name implies, CD-RW enables you to erase and overwrite information in addition to reading and writing. The Orange Book Part III CD-RW definition is broken into three volumes. Volume 1 defines recording speeds of 1x, 2x, and 4x times the standard CD speed; the latest version, 2.0, is dated August 1998. Volume 2 (high-speed) defines recording speeds from 4x to 10x standard CD speed; the latest version, 1.1, is dated June 2001. Volume 3 (ultra-speed) defines recording speeds from 8x to 32x; the latest version, 0.5, is dated April 2002.

Besides the capability to record on CDs, the most important feature instituted in the Orange Book specification is the capability to perform multisession recording.

Multisession Recording

Before the Orange Book specification, CDs had to be written as a single session. A *session* is defined as a lead-in, followed by one or more tracks of data (or audio), followed by a lead-out. The lead-in takes up 4,500 sectors on the disc (1 minute if measured in time or about 9.2MB worth of data). The lead-in also indicates whether the disc is multisession and what the next writable address on the disc is (if the disc isn't closed). The first lead-out on a disc (or the only one if it is a single session or Disk At Once recording) is 6,750 sectors long (1.5 minutes if measured in time or about 13.8MB worth of data). If the disc is a multisession disc, any subsequent lead-outs are 2,250 sectors long (0.5 minutes in time or about 4.6MB worth of data).

A multisession CD has multiple sessions, with each individual session complete from lead-in to lead-out. The mandatory lead-in and lead-out for each session do waste space on the disc. In fact, 48 sessions would literally use up all of a 74-minute disc even with no data recorded in each session! Therefore, the practical limit for the number of sessions you can record on a disc would be much less than that.

CD-DA and older CD-ROM drives couldn't read more than one session on a disc, so that is the way most pressed CDs are recorded. The Orange Book allows multiple sessions on a single disc. To allow this, the Orange Book defines three main methods or modes of recording:

- Disk-at-Once (DAO)
- Track-at-Once (TAO)
- Packet Writing

Disc-at-Once

Disc-at-Once means pretty much what it says: It is a single- session method of writing CDs in which the lead-in, data tracks, and lead-out are written in a single operation without ever turning off the writing laser; then the disc is closed. A disc is considered closed when the last (or only) lead-in is fully written and the next usable address on the disc is not recorded in that lead-in. In that case, the CD recorder is incapable of writing any further data on the disc. Note that it is not necessary to close a disc to read it in a normal CD-ROM drive, although if you were submitting a disc to a CD duplicating company for replication, most require that it be closed.

Track-at-Once

Multisession discs can be recorded in either Track-at-Once (TAO) or Packet Writing mode. In Track-at-Once recording, each track can be individually written (laser turned on and off) within a session, until the session is closed. Closing a session is the act of writing the lead-out for that session, which means no more tracks can be added to that session. If the disc is closed at the same time, no further sessions can be added either.

The tracks recorded in TAO mode are typically divided by gaps of 2 seconds. Each track written has 150 sectors of overhead for run-in, run-out, pre-gap, and linking. A CD-R/RW drive can read the tracks even if the session is not closed, but to read them in a CD-DA or CD-ROM drive, the session must be closed. If you intend to write more sessions to the disc, you can close the session and not close the disc. At that point, you could start another session of recording to add more tracks to the disc. The main thing to remember is that each session must be closed (lead-out written) before another session can be written or before a normal CD-DA or CD-ROM drive can read the tracks in the session.

Packet Writing

Packet writing is a method whereby multiple writes are allowed within a track, thus reducing the overhead and wasted space on a disc. Each packet uses 4 sectors for run-in, 2 for run-out, and 1 for linking. Packets can be of fixed or variable length, but most drives and packet-writing software use a fixed length because dealing with file systems that way is much easier and more efficient.

With packet writing, you use the Universal Disk Format (UDF) version 1.5 or later file system, which enables the CD to be treated essentially like a big floppy drive. That is, you can literally drag and drop files to it, use the copy command to copy files onto the disc, and so on. The packet-writing software and UDF file system manage everything. If the disc you are using for packet writing is a CD-R, every time a file is overwritten or deleted, the file seems to disappear, but you don't get the space back on the disc. Instead, the file system simply forgets about the file. If the disc is a CD-RW, the space is indeed reclaimed and the disc won't be full until you literally have more than the limit of active files stored there.

Unfortunately, Windows versions up through Windows XP don't support packet writing or the UDF file system directly, so drivers must be loaded to read packet-written discs and a packet-writing application must be used to write them. Fortunately, though, these typically are included with CD-RW drives. One of the most popular packet-writing programs is DirectCD from Roxio. You can even download a universal UDF reader application from Roxio for free that enables you to read UDF 1.5 (packet-written) discs on any CD-ROM or CD-RW drive.

Note

Windows XP also has limited CD-RW support in the form of something called IMAPI (image mastering application program interface), which enables data to be temporarily stored on the hard drive (staged) before being written to the CD in one session. Additional sessions can be written to the same disc, but a 50MB overhead exists for each session. This gives

some of the appearance of packet writing, but it is not really the same thing. To read packet-written discs in the UDF 1.5 or later format, you must install a UDF reader just as with previous versions of Windows.

When you remove a packet-written disc from the drive, the packet-writing software first asks whether you want the files to be visible to normal CD-ROM drives. If you do then the session must be closed. Even if the session is closed, you can still write more to the disc later, but there is an overhead of wasted space every time you close a session. If you are going to read the disc in a CD-RW drive, you don't have to close the session because it will be capable of reading the files even if the session isn't closed.

A newer standard called Mount Rainier adds even more capability to packet writing and is one of the most important developments in CD and DVD drives. With Mount Rainier, packet writing can become an official part of the operating system and the drives can support the defect management necessary to make them usable as removable storage in the real world. For more information, see the section "Mount Rainier" later in this chapter.

Note

Microsoft has released updates for Windows XP that add native support for the Mount Rainier standard, which supports full drag-and-drop packet writing through CD-MRW drives as well as DVD+MRW drives.

Photo CD

First announced back in 1990 but not available until 1992, Photo CD is a standard for CD-R discs and drives to store photos. You simply drop off a roll of film at a participating Kodak developer, and they digitize and store the photos on a specially formatted CD-R disc called a Photo CD, which you can then read on virtually any CD-ROM drive connected to a PC running the appropriate software. Originally, Kodak sold Photo CD "players" designed to display the photos to a connected TV, but these have since been dropped in favor of simply using a PC with software to decode and display the photos.

Perhaps the main benefit Photo CD has brought to the table is that it was the first CD format to use the Orange Book Part II (CD-R) specification with multisession recordings. Additionally, the data is recorded in CD-ROM XA Mode 2, Form 2 sectors so more photo information could be stored on the disc.

Using the Photo CD software, you can view your photographs at any one of several resolutions and manipulate them using standard graphics software packages.

When you drop off your roll of film, the Kodak developers produce prints as they normally do. After prints are made, they scan the prints with ultra-high-resolution scanners. To give you an idea of the amount of information each scan carries, one color photograph can take 15MB–20MB of storage. The compressed, stored images are then encoded onto special writable CDs, and the finished product is packaged and shipped back to your local developer for pickup. Some developers can do the scanning on-site.

Photo CD Disc Types

The images on the disc are compressed and stored using Kodak's own PhotoYCC encoding format, which includes up to six resolutions for each image, as shown in Table 13.15. Kodak has defined several types of Photo CD discs to accommodate the needs of various types of users. The Photo CD Master disc is the standard consumer format and contains up to 100 photos in all the resolutions shown in the table except for base x64.

Table 13.15 Photo CD Resolutions

Base	Resolution (pixels)	Description
/16	128×192	Thumbnail
/4	256×384	Thumbnail
x1	512×768	TV resolution
x4	1,024×1,536	HDTV resolution
x16	2,048×3,072	Print size
x64	4,096×6,144	Pro Photo CD master only

The various resolutions supply you with images appropriate for various applications. If, for example, you wanted to include a Photo CD image on a Web page, you would choose a low-resolution image. A professional photographer shooting photos for a print ad would want to use the highest resolution possible.

The Pro Photo CD Master disc is intended for professional photographers using larger film formats, such as 70mm, 120mm, or 4"×5". This type of disc adds an even higher-resolution image (4,096×6,144 pixels) to those already furnished on the Photo CD Master disc. Because of this added high-resolution image, this type of disc can hold anywhere from 25 to 100 images, depending on the film format.

The Photo CD Portfolio disc is designed for interactive presentations that include sound and other multimedia content. The high-resolution images that take up the most space are not necessary here, so this type of disc can contain up to 700 images, depending on how much other content is included.

Multisession Photo CDs

One breakthrough of the Photo CD concept is that each of the disc types is capable of containing multiple sessions. Because the average consumer wouldn't usually have enough film processed to fill an entire disc, you can bring back your partially filled CDs each time you have more film to develop. A new session can then be added to your existing CD until the entire disc is filled. You pay less for the processing because a new CD is not necessary, and all your images are stored on a smaller number of discs.

Any XA-compliant or XA-ready CD-ROM drive can read the multiple sessions on a Photo CD disc, and even if your drive is not multisession capable, it can still read the first session on the disc. If this is the case, you must purchase a new disc for each batch of film you process, but you can still take advantage of Photo CD technology.

Kodak provides software that enables you to view the Photo CD images on your PC and licenses a Photo CD import filter to the manufacturers of many desktop publishing, image-editing, and paint programs. Therefore, you can modify your Photo CD images using a program such as Adobe Photoshop and integrate them into documents for printing or electronic publication with a page layout program such as Adobe PageMaker.

Picture CD

Although Kodak still offers Photo CD services, the high cost has led to limited popularity. Kodak now offers the simpler Picture CD service. Unlike Photo CD, Picture CD uses the industry-standard JPEG file format. It uses a CD-R, with up to 40 images stored at a single medium-resolution scan of 1,024×1,536 pixels. This resolution is adequate for 4"×6" and 5"×7" prints. The images can also be made available via Kodak PhotoNet, where the same images are posted online and can be downloaded. In addition, Kodak has a service called Picture Disk that stores up to 28 images on a 1.44MB floppy disk at a resolution of 400×600, suitable for screensavers and slide shows.

The software provided with Picture CD enables the user to manipulate images with various automatic or semiautomatic operations, but unlike Photo CD, the standard JPEG (JPG) file format used for storage enables any popular image-editing program to work with the images without conversion. Although the image quality of Picture CD isn't as high as with Photo CD, the much lower price of the service should make it far more popular with amateur photographers.

White Book—Video CD

The White Book was introduced in 1993 by Philips, JVC, Matsushita, and Sony. It is based on the Green Book (CD-i) and CD-ROM XA standards and allows for storing up to 74 minutes of MPEG-1 video and ADPCM digital audio data on a single disc. The latest version was released in April 1995.

You can think of video CDs as a sort of poor man's DVD format, although the picture and sound quality can actually be quite good—certainly better than VHS or most other videotape formats. You can play video CDs on virtually any PC with a CD-ROM drive using the free Windows Media Player (other media player applications can be used as well). They also can be played on most DVD players and even some game consoles, such as the Playstation (with the correct options). Video CDs are an especially big hit with people who travel with laptop computers, and the prerecorded discs are much cheaper than DVD—many cost as little as $5.

Blue Book—CD EXTRA

Manufacturers of CD-DA media were looking for a standard method to combine both music and data on a single CD. The intention was for a user to be able to play only the audio tracks in a standard audio CD player while remaining unaware of the data track. However, a user with a PC or dedicated combination audio/data player could access both the audio and data tracks on the same disc.

The fundamental problem with nonstandard mixed-mode CDs is that if or when an audio player tries to play the data track, the result is static that could conceivably damage speakers and possibly hearing if the volume level has been turned up. Various manufacturers originally addressed this problem in different ways, resulting in a number of confusing methods for creating these types of discs, some of which still allowed the data tracks to be accidentally "played" on an audio player. In 1995, Philips and Sony developed the CD EXTRA specification, as defined in the Blue Book standard. CDs conforming to this specification usually are referred to as CD EXTRA (formerly called CD Plus or CD Enhanced Music) discs and use the multisession technology defined in the CD-ROM XA standard to separate the audio and data tracks. These are a form of stamped multisession disc. The audio portion of the disc can consist of up to 98 standard Red Book audio tracks, whereas the data track typically is composed of XA Mode 2 sectors and can contain video, song lyrics, still images, or other multimedia content. Such discs can be identified by the CD EXTRA logo, which is the standard CD-DA logo with a plus sign to the right. Often the logo or markings on the disc package are overlooked or somewhat obscure, and you might not know that an audio CD contains this extra data until you play it in a CD-ROM drive.

A CD EXTRA disc normally contains two sessions. Because audio CD players are only single-session capable, they play only the audio session and ignore the additional session containing the data. A CD-ROM drive in a PC, however, can see both sessions on the disc and access both the audio and data tracks.

Note

Many artists have released audio CDs in the CD EXTRA format that include things such as lyrics, video, artist bio, photos, and so on in data files on the disc. *Tidal* by Fiona Apple (released in 1996) was one of the first CD EXTRA discs from Sony Music. There have been many CD EXTRA releases since then. For examples of other CD EXTRA discs, including current releases, see `http://www.cdextra.com`.

CD-ROM File Systems

Manufacturers of early CD-ROM discs required their own custom software to read the discs. This is because the Yellow Book specification for CD-ROM details only how data sectors—rather than audio sectors—can be stored on a disc and did not cover the file systems or deal with how data should be stored in files and how these should be formatted for use by PCs with different operating systems. Obviously, noninterchangeable file formats presented an obstacle to the industry-wide compatibility for CD-ROM applications.

In 1985–1986, several companies got together and published the High Sierra file format specification, which finally enabled CD-ROMs for PCs to be universally readable. That was the first industry-standard CD-ROM file system that made CD-ROMs universally usable in PCs. Today several file systems are used on CDs, including

- High Sierra
- ISO 9660 (based on High Sierra)
- Joliet
- UDF (Universal Disk Format)
- Mac HFS (Hierarchical File Format)
- Rock Ridge

Not all CD file system formats can be read by all operating systems. Table 13.16 shows the primary file systems used and which operating systems support them.

Table 13.16 CD File System Formats

CD File System	DOS/Win 3.x	Win 9x/Me	Win NT/2000/XP	Mac OS
High Sierra	Yes	Yes	Yes	Yes
ISO 9660	Yes	Yes	Yes	Yes
Joliet	Yes[1]	Yes	Yes	Yes[1]
UDF	No	Yes[2]	Yes[2]	Yes[2]
Mac HFS	No	No	No	Yes
Rock Ridge	Yes[1]	Yes[1]	Yes[1]	Yes[1]

1. A short name, such as (SHORTN~1.TXT), will be shown in place of long filenames.

2. Only if a third-party UDF reader is installed.

Note

The Mac HFS and Unix Rock Ridge file systems are not supported by PC operating systems such as DOS or Windows and therefore are not covered in depth here.

High Sierra

To make CD-ROM discs readable on all systems without having to develop custom file systems and drivers, it was in the best interests of all PC hardware and software manufacturers to resolve the CD-ROM file format standardization issue. In 1985, representatives from TMS, DEC, Microsoft, Hitachi, LaserData, Sony, Apple, Philips, 3M, Video Tools, Reference Technology, and Xebec met at

what was then called the High Sierra Hotel and Casino in Lake Tahoe, Nevada, to create a common logical format and file structure for CD-ROMs. In 1986, they jointly published this standard as the "Working Paper for Information Processing: Volume and File Structure of CD-ROM Optical Discs for Information Exchange (1986)." This standard was subsequently referred to as the High Sierra format.

This agreement enabled all drives using the appropriate driver (such as MSCDEX.EXE supplied by Microsoft with DOS) to read all High Sierra format discs, opening the way for the mass production and acceptance of CD-ROM software publishing. Adoption of this standard also enabled disc publishers to provide cross-platform support for their software and easily manufacture discs for DOS, Unix, and other operating system formats. Without this agreement, the maturation of the CD-ROM marketplace would have taken years longer and the production of CD-ROM-based information would have been stifled.

The High Sierra format was submitted to the International Organization for Standardization (ISO). Two years later (in 1988), with several enhancements and changes, it was republished as the ISO 9660 standard. ISO 9660 was not exactly the same as High Sierra, but all drivers that would read High Sierra–formatted discs were quickly updated to handle both ISO 9660 and the original High Sierra format on which it was based.

For example, Microsoft wrote the MSCDEX.EXE (Microsoft CD-ROM extensions) driver in 1988 and licensed it to CD-ROM hardware and software vendors to include with their products. It wasn't until 1993 when MS-DOS 6.0 was released that MSCDEX was included with DOS as a standard feature. MSCDEX enables DOS to read ISO 9660–formatted (and High Sierra–formatted) discs. This driver works with the AT Attachment Packet Interface (ATAPI) or Advanced SCSI Programming Interface (ASPI) hardware-level device driver that comes with the drive. Microsoft built ISO 9660 and Joliet file system support directly into Windows 95 and later, with no additional drivers necessary.

ISO 9660

The ISO 9660 standard enabled full cross compatibility among different computer and operating systems. ISO 9660 was released in 1988 and was based on the work done by the High Sierra group. Although based on High Sierra, ISO 9660 does have some differences and refinements. It has three levels of interchange that dictate the features that can be used to ensure compatibility with different systems.

ISO 9660 Level 1 is the lowest common denominator of all CD file systems and is capable of being read by almost every computer platform, including Unix and Macintosh. The downside of this file system is that it is very limited with respect to filenames and directories. Level 1 interchange restrictions include

- Only uppercase characters A–Z, numbers 0–9, and the underscore (_) are allowed in filenames.
- 8.3 characters maximum for the name.extension (based on DOS limits).
- Directory names are eight characters maximum (no extension allowed).
- Directories are limited to eight levels deep.
- Files must be contiguous.

Level 2 interchange rules have the same limitations as Level 1, except that the filename and extension can be up to 30 characters long (both added together, not including the . separator). Finally, Level 3 interchange rules are the same as Level 2 except that files don't have to be contiguous.

Note that Windows 95 and later versions enable you to use file and folder names up to 255 characters long, which can include spaces as well lowercase and many other characters not allowed in ISO 9660. To maintain backward compatibility with DOS, Windows 95 and later associate a short 8.3 format

filename as an alias for each file that has a longer name. These alias short names are created automatically by Windows and can be viewed in the Properties for each file or by using the `DIR` command at a command prompt. To create these alias names, Windows truncates the name to six (or fewer) characters followed by a tilde (~) and a number starting with 1 and truncates the extension to three characters. Other numbers are used in the first part if other files that would have the same alias when truncated already exist. For example, the filename `This is a.test` gets `THISIS~1.TES` as an alias.

This filename alias creation is independent of your CD drive, but it is important to know that if you create or write to a CD using the ISO 9660 format using Level 1 restrictions, the alias short names are used when recording files to the disc, meaning any long filenames will be lost in the process. In fact, even the alias short name will be modified because ISO 9660 Level 1 restrictions don't allow a tilde—that character is converted to an underscore in the names written to the CD.

The ISO 9660 data starts at 2 seconds and 16 sectors into the disc, which is also known as *logical sector 16 of track one*. For a multisession disc, the ISO 9660 data is present in the first data track of each session containing CD-ROM tracks. This data identifies the location of the volume area—where the actual data is stored. The system area also lists the directories in this volume as the volume table of contents (VTOC), with pointers or addresses to various named areas, as illustrated in Figure 13.6. A significant difference between the CD directory structure and that of a normal hard disk is that the CD's system area also contains direct addresses of the files within the subdirectories, allowing the CD to seek specific sector locations on the spiral data track. Because the CD data is all on one long spiral track, when speaking of tracks in the context of a CD, we're actually talking about sectors or segments of data along that spiral.

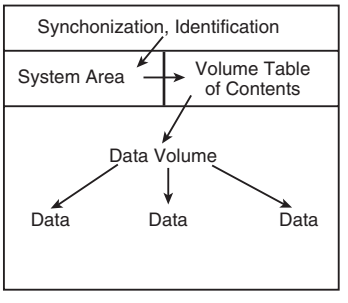

Figure 13.6 A diagram of basic ISO 9660 file organizational format.

To put the ISO 9660 format in perspective, the disc layout is roughly analogous to that of a floppy disk. A floppy disk has a system track that not only identifies itself as a floppy disk and reveals its density and operating system, but also tells the computer how it's organized (into directories, which are made up of files).

Joliet

Joliet is an extension of the ISO 9660 standard that Microsoft developed for use with Windows 95 and later. Joliet enables CDs to be recorded using filenames up to 64 characters long, including spaces and other characters from the Unicode international character set. Joliet also preserves an 8.3 alias for those programs that can't use the longer filenames.

In general, Joliet features the following specifications:

- File or directory names can be up to 64 Unicode characters (128 bytes) in length.
- Directory names can have extensions.

- Directories can be deeper than eight levels.
- Multisession recording is inherently supported.

Due to backward-compatibility provisions, systems that don't support the Joliet extensions (such as older DOS systems) should still be capable of reading the disc. However, it will be interpreted as an ISO 9660 format using the short names instead.

Note

A bit of trivia: "Chicago" was the code name used by Microsoft for Windows 95. Joliet is the town outside of Chicago where Jake was locked up in the movie *The Blues Brothers*.

Universal Disk Format

UDF is a relatively new file system created by the Optical Storage Technology Association (OSTA) as an industry-standard format for use on optical media such as CD-ROM and DVD. UDF has several advantages over the ISO 9660 file system used by standard CD-ROMs but is most noted because it is designed to work with packet writing, a technique for writing small amounts of data to a CD-R/RW disc, treating it much like a standard magnetic drive.

The UDF file system allows long filenames up to 255 characters per name. There have been several versions of UDF, with most packet-writing software using UDF 1.5 or later. Packet-writing software such as DirectCD from Roxio writes in the UDF file system. However, standard CD-ROM drives, drivers, or operating systems such as DOS can't read UDF-formatted discs. Recordable drives can read them, but regular CD-ROM drives must conform to the MultiRead specification (see the section "MultiRead Specifications," later in this chapter) to be capable of reading UDF discs.

After you are sure that your drive can read UDF, you must check the OS. Most operating systems can't read UDF natively—the support has to be added via a driver. DOS can't read UDF at all; however, with Windows 95 and later, UDF-formatted discs can be read by installing a UDF driver. Typically, such a driver is included with the software that comes with most CD-RW drives. If you don't have a UDF driver, you can download one for free from Roxio at `http://www.roxio.com`. The Roxio UDF Reader is included with DirectCD 3.0 and later. After the UDF driver is installed, you do not need to take any special steps to read a UDF-formatted disc. The driver will be in the background waiting for you to insert a UDF-formatted disc.

You can close a DirectCD for Windows disc to make it readable in a normal CD-ROM drive, which converts the filenames to Joliet format and causes them to be truncated to 64 characters.

Macintosh HFS

HFS is the file system used by the Macintosh OS. HFS can also be used on CD-ROMs; however, if that is done, they will not be readable on a PC. A hybrid disc can be produced with both Joliet and HFS or ISO 9660 and HFS file systems, and the disc would then be readable on both PCs and Macs. In that case, the system will see only the disc that is compatible, which is ISO 9660 or Joliet in the case of PCs.

Rock Ridge

The Rock Ridge Interchange Protocol (RRIP) was developed by an industry consortium called the Rock Ridge group. It was officially released in 1994 by the IEEE CD-ROM File System Format Working Group and specifies an extension to the ISO 9660 standard for CD-ROM that enables the recording of additional information to support Unix/POSIX file system features. Neither DOS nor Windows

include support for the Rock Ridge extensions. However, because it is based on ISO 9660, the files are still readable on a PC and the RRIP extensions are simply ignored.

Note

An interesting bit of trivia is that the Rock Ridge name was taken from the fictional Western town in the movie *Blazing Saddles*.

DVD

DVD stands for digital versatile disc and in simplest terms is a high-capacity CD. In fact, every DVD-ROM drive *is* a CD-ROM drive; that is, they can read CDs as well as DVDs (many DVD players can't read CD-R or CD-RW discs, however). DVD uses the same optical technology as CD, with the main difference being higher density. The DVD standard dramatically increases the storage capacity of, and therefore the useful applications for, CD-ROM-sized discs. A CD-ROM can hold a maximum of about 737MB (80-minute disc) of data, which might sound like a lot but is simply not enough for many up-and-coming applications, especially where the use of video is concerned. DVD discs, on the other hand, can hold up to 4.7GB (single layer) or 8.5GB (dual layer) on a single side of the disc, which is more than 11 1/2 times greater than a CD. Double-sided DVD discs can hold up to twice that amount, although you currently must manually flip the disc over to read the other side.

Up to two layers of information can be recorded to DVD discs, with an initial storage capacity of 4.7GB of digital information on a single-sided, single-layer disc—a disk that is the same overall diameter and thickness of a current CD-ROM. With Moving Picture Experts Group–standard 2 (MPEG-2) compression, that's enough to contain approximately 133 minutes of video, which is enough for a full-length, full-screen, full-motion feature film—including three channels of CD-quality audio and four channels of subtitles. Using both layers, a single-sided disc could easily hold 240 minutes of video or more. This initial capacity is no coincidence; the creation of DVD was driven by the film industry, which has long sought a storage medium cheaper and more durable than videotape.

Note

It is important to know the difference between the DVD-Video and DVD-ROM standards. DVD-Video discs contain only video programs and are intended to be played in a DVD player connected to a television and possibly an audio system. DVD-ROM is a data storage medium intended for use by PCs and other types of computers. The distinction is similar to that between an audio CD and a CD-ROM. Computers might be capable of playing audio CDs as well as CD-ROMs, but dedicated audio CD players can't use a CD-ROM's data tracks. Likewise, computer DVD drives can play DVD-video discs (with MPEG-2 decoding in either hardware or software), but DVD video players can't access data on a DVD-ROM.

The initial application for DVDs was as an upgrade for CDs as well as a replacement for prerecorded videotapes. DVDs can be rented or purchased like prerecorded VCR tapes, but they offer much higher resolution and quality with greater content. As with CDs, which initially were designed only for music, DVDs have since developed into a wider range of uses, including computer data storage and high-quality audio.

DVD History

DVD had a somewhat rocky start. During 1995, two competing standards for high-capacity CD-ROM drives were being developed to compete with each other for future market share. One standard, called Multimedia CD, was introduced and backed by Philips and Sony, whereas a competing standard, called the Super Density (SD) disk, was introduced and backed by Toshiba, Time Warner, and several

other companies. If both standards had hit the market as is, consumers as well as entertainment and software producers would have been in a quandary over which one to choose.

Fearing a repeat of the Beta/VHS situation that occurred in the videotape market, several organizations, including the Hollywood Video Disc Advisory Group and the Computer Industry Technical Working Group, banded together to form a consortium to develop and control the DVD standard. The consortium insisted on a single format for the industry and refused to endorse either competing proposal. With this incentive, both groups worked out an agreement on a single, new, high-capacity CD type disc in September of 1995. The new standard combined elements of both previously proposed standards and was called DVD, which originally stood for digital video disc, but has since been changed to digital versatile disc. The single DVD standard has avoided a confusing replay of the VHS versus Beta tape fiasco and has given the software, hardware, and movie industries a single, unified standard to support.

After agreeing on copy protection and other items, the DVD-ROM and DVD-Video standards were officially announced in late 1996. Players, drives, and discs were announced in January 1997 at the Consumer Electronics Show (CES) in Las Vegas, and the players and discs became available in March of 1997. The initial players were about $1,000 each. Only 36 movies were released in the first wave, and they were available only in seven cities nationwide (Chicago, Dallas, Los Angeles, New York, San Francisco, Seattle, and Washington, D.C.) until August 1997 when the full release began. After a somewhat rocky start (much had to do with agreements on copy protection to get the movie companies to go along, and there was a lack of titles available in the beginning), DVD has become an incredible success. It will continue to grow as DVD moves from a read-only to a fully rewritable consumer as well as computer device.

The organization that controls the DVD video standard is called the DVD Forum and was founded by 10 companies, including Hitachi, Matsushita, Mitsubishi, Victor, Pioneer, Sony, Toshiba, Philips, Thomson, and Time Warner. Since its founding in April 1997, more than 230 companies have joined the forum. Because it is a public forum, anybody can join and attend the meetings; the site for the DVD forum is `http://www.dvdforum.org`. Because the DVD Forum was unable to agree on a universal recordable format, its members who are primarily responsible for CD and DVD (Philips, Sony, and others) technology split off to form the DVD+RW Alliance in June 2000; their site is `http://www.dvdrw.org`. They have since introduced the DVD+RW format, which is by far the most flexible and backward-compatible recordable DVD format. DVD+RW will replace not only the VCR at home, but also both the CD-RW and floppy drives in your PC.

DVD Technology

DVD technology is similar to CD technology. Both use the same size (120mm diameter, 1.2mm thick, with a 15mm hole in the center) discs with pits and lands stamped in a polycarbonate base. Unlike a CD, though, DVDs can have two layers of recordings on a side and be double-sided as well. Each layer is separately stamped, and they are all bonded together to make the final 1.2mm-thick disc. The manufacturing process is largely the same, with the exception that each layer on each side is stamped from a separate piece of polycarbonate plastic and are then bonded together to form the completed disc. The main difference between CD and DVD is that DVD is a higher-density recording read by a laser with a shorter wavelength, focused more closely to the disc, which enables more information to be stored. Also, whereas CDs are single-sided and have only one layer of stamped pits and lands, DVDs can have up to two layers per side and can have information on both sides.

As with CDs, each layer is stamped or molded with a single physical track in a spiral configuration starting from the inside of the disc and spiraling outward. The disc rotates counterclockwise (as viewed from the bottom), and each spiral track contains pits (bumps) and lands (flat portions) just as on a CD. Each recorded layer is coated with a thin film of metal to reflect the laser light. The outer

layer has a thinner coating to allow the light to pass through to read the inner layer. If the disc is single-sided, a label can be placed on top; if it's double-sided, only a small ring near the center provides room for labeling.

Just as with a CD, reading the information back on a DVD is a matter of bouncing a low-powered laser beam off one of the reflective layers in the disc. The laser shines a focused beam on the underside of the disc, and a photosensitive receptor detects when the light is reflected back. When the light hits a land (flat spot) on the track, the light is reflected back; when the light hits a pit (raised bump), the phase differential between the projected and reflected light causes the waves to cancel and no light is reflected back.

The individual pits on a DVD are 0.105 microns deep and 0.4 microns wide. Both the pits and lands vary in length from about 0.4 microns at their shortest to about 1.9 microns at their longest (on single-layer discs).

Refer to the section "CD-ROM Technology," earlier in this chapter, for more information on how the pits and lands are read and converted into actual data, as well as how the drives physically and mechanically work.

DVD uses the same optical laser read pit and land storage that CDs do. The greater capacity is made possible by several factors, including the following:

- A 2.25 times smaller pit length (0.9–0.4 microns)
- A 2.16 times reduced track pitch (1.6–0.74 microns)
- A slightly larger data area on the disc (8,605–8,759 square millimeters)
- About 1.06 times more efficient channel bit modulation
- About 1.32 times more efficient error correction code
- About 1.06 times less sector overhead (2,048/2,352–2,048/2,064 bytes)

The DVD disc's pits and lands are much smaller and closer together than those on a CD, allowing the same physical-sized platter to hold much more information. Figure 13.7 shows how the grooved tracks with pits and lands are just over four times as dense on a DVD as compared to a CD.

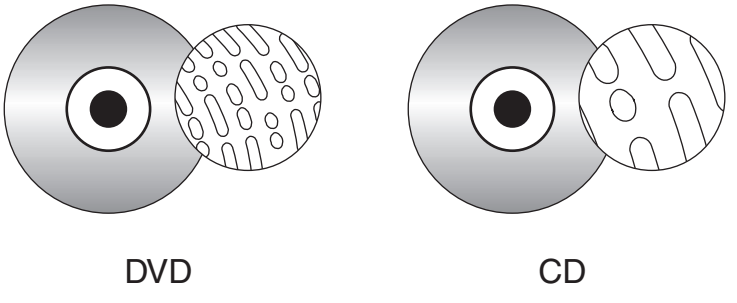

Figure 13.7 DVD data markings (pits and lands) versus those of a standard CD.

DVD drives use a shorter wavelength laser to read these smaller pits and lands. A DVD can have nearly double the initial capacity by using two separate layers on one side of a disc and double it again by using both sides of the disc. The second data layer is written to a separate substrate below the first layer, which is then made semireflective to enable the laser to penetrate to the substrate beneath it. By focusing the laser on one of the two layers, the drive can read roughly twice the amount of data from the same surface area.

DVD Tracks and Sectors

The pits are stamped into a single spiral track (per layer) with a spacing of 0.74 microns between turns, corresponding to a track density of 1,351 turns per millimeter or 34,324 turns per inch. This equates to a total of 49,324 turns and a total track length of 11.8km or 7.35 miles in length. The track is comprised of sectors, with each sector containing 2,048 bytes of data. The disc is divided into four main areas:

- *Hub clamping area*. The hub clamp area is just that, a part of the disc where the hub mechanism in the drive can grip the disc. No data or information is stored in that area.
- *Lead-in zone*. The lead-in zone contains buffer zones, reference code, and mainly a control data zone with information about the disc. The control data zone consists of 16 sectors of information repeated 192 times for a total of 3,072 sectors. Contained in the 16 (repeated) sectors is information about the disc, including disc category and version number, disc size and maximum transfer rate, disc structure, recording density, and data zone allocation. The entire lead-in zone takes up to 196,607 (2FFFFh) sectors on the disc. Unlike CDs, the basic structure of all sectors on a DVD are the same. The buffer zone sectors in the lead-in zone have all 00h (zero hex) recorded for data.
- *Data zone*. The data zone contains the video, audio, or other data on the disc and starts at sector number 196,608 (30000h). The total number of sectors in the data zone can be up to 2,292,897 per layer for single layer discs.
- *Lead-out (or middle) zone*. The lead-out zone marks the end of the data zone. The sectors in the lead-out zone all contain zero (00h) for data. This is called the middle zone if the disc is dual layer and is recorded in opposite track path (OPT) mode, in which the second layer starts from the outside of the disc and is read in the opposite direction from the first layer.

The center hole in a DVD is 15mm in diameter, so it has a radius of 7.5mm from the center of the disc. From the edge of the center hole to a point at a radius of 16.5mm is the hub clamp area. The lead-in zone starts at a radius of 22mm from the center of the disc. The data zone starts at a radius of 24mm from the center and is followed by the lead-out (or middle) zone at 58mm. The disc track officially ends at 58.5mm, which is followed by a 1.5mm blank area to the edge of the disc. Figure 13.8 shows these zones in actual relative scale as they appear on a DVD.

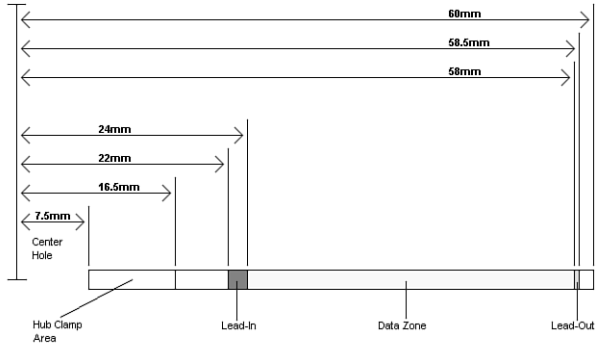

Figure 13.8 Areas on a DVD (side view).

Officially, the spiral track of a standard DVD starts with the lead-in zone and ends at the finish of the lead-out zone. This single spiral track is about 11.84 kilometers or 7.35 miles long. An interesting fact is that in a 20x CAV drive, when reading the outer part of the track, the data moves at an actual speed

of 156 miles per hour (251km/h) past the laser. What is more amazing is that even when the data is traveling at that speed, the laser pickup can accurately read bits (pit/land transitions) spaced as little as only 0.4 microns or 15.75 millionths of an inch apart!

DVDs come in both single- and dual-layer as well as single- and double-sided versions. The double-sided discs are essentially the same as two single-sided discs glued together back to back, but subtle differences do exist between the single- and dual-layer discs. Table 13.17 shows some of the basic information about DVD technology, including single- and dual-layer DVDs. The dual-layer versions are recorded with slightly longer pits, resulting in slightly less information being stored in each layer.

Table 13.17 DVD Technical Parameters

DVD Type:	Single-Layer	Dual-Layer
1x read speed (m/sec)	3.49	3.84
Laser wavelength (nm)	650	650
Numerical aperture(lens)	0.60	0.60
Media refractive index	1.55	1.55
Track (turn) spacing (um)	0.74	0.74
Turns per mm	1,351	1,351
Turns per inch	34,324	34,324
Total track length (m)	11,836	11,836
Total track length (feet)	38,832	38,832
Total track length (miles)	7.35	7.35
Media bit cell length (nm)	133.3	146.7
Media byte length (um)	1.07	1.17
Media sector length (mm)	5.16	5.68
Pit width (um)	0.40	0.40
Pit depth (um)	0.105	0.105
Min. nominal pit length (um)	0.40	0.44
Max. nominal pit length (um)	1.87	2.05
Lead-in inner radius (mm)	22	22
Data zone inner radius (mm)	24	24
Data zone outer radius (mm)	58	58
Lead-out outer radius (mm)	58.5	58.5
Data zone width (mm)	34	34
Data zone area (mm2)	8,759	8,759
Total track area width (mm)	36.5	36.5

Table 13.17 Continued

DVD Type:	Single-Layer	Dual-Layer
Max. rotating speed 1x CLV (rpm)	1,515	1,667
Min. rotating speed 1x CLV (rpm)	570	627
Track revolutions (data zone)	45,946	45,946
Track revolutions (total)	49,324	49,324
Data zone sectors per layer per side	2,292,897	2,083,909
Sectors per second	676	676
Media data rate (mbits/sec)	26.15625	26.15625
Media bits per sector	38,688	38,688

Interface data rate (mbits/sec)	11.08	11.08
Interface data bits per sector	16,384	16,384
Interface data bytes per sector	2,048	2,048
Track time per layer (minutes)	56.52	51.37
Track time per side (minutes)	56.52	102.74
MPEG-2 video per layer (minutes)	133	121
MPEG-2 video per side (minutes)	133	242

B = Byte (8 bits)
KB = Kilobyte (1,000 bytes)
KiB = Kibibyte (1,024 bytes)
MB = Megabyte (1,000,000 bytes)
MiB = Mebibyte (1,048,576 bytes)
GB = Gigabyte (1,000,000,000 bytes)
GiB = Gibibyte (1,073,741,824 bytes)
m = meters
mm = millimeters (thousandths of a meter)
mm2 = square millimeters
um = micrometers = microns (millionths of a meter)
nm = nanometers (billionths of a meter)
rpm = revolutions per minute
ECC = Error correction code
EDC = Error detection code
CLV = Constant linear velocity
CAV = Constant angular velocity

As you can see from the information in Table 13.17, the spiral track is divided into sectors that are stored at the rate of 676 sectors per second. Each sector contains 2,048 bytes of data.

When being written, the sectors are first formatted into data frames of 2,064 bytes: 2,048 are data, 4 bytes contain ID information, 2 bytes contain ID error detection (IED) codes, 6 bytes contain copyright information, and 4 bytes contain EDC for the frame.

The data frames then have ECC information added to convert them into ECC frames. Each ECC frame contains the 2,064-byte data frame plus 182 parity outer (PO) bytes and 120 parity inner (PI) bytes, for a total of 2,366 bytes for each ECC frame.

Finally, the ECC frames are converted into physical sectors on the disc. This is done by taking 91 bytes at a time from the ECC frame and converting them into recorded bits via 8 to 16 modulation. This is where each byte (8 bits) is converted into a special 16-bit value, which is selected from a

table. These values are designed using an RLL 2,10 scheme, which is designed so that the encoded information never has a run of less than 2 or more than 10 0 bits in a row. After each group of 91 bytes is converted via the 8 to 16 modulation, 320 bits (4 bytes) of synchronization information is added. After the entire ECC frame is converted into a physical sector, 4,836 total bytes are stored.

Table 13.18 shows the sector, frame, and audio data calculations.

Table 13.18 DVD Data Frame, ECC Frame, and Physical Sector Layout and Information

DVD Data Frame:	
Identification data (ID) bytes	4
ID error detection code (IED) bytes	2
Copyright info (CI) bytes	6
Data bytes	2,048
Error detection code (EDC)	4
Data frame total bytes	2,064
DVD ECC Frame:	
Data frame total bytes	2,064
Parity outer (PO) bytes	182
Parity inner (PI) bytes	120
ECC frame total bytes	2,366
DVD Media Physical Sectors:	
ECC frame bytes	2,366
8 to 16 modulation bits	37,856
Synchronization bits	832
Total encoded media bits/sector	38,688
Total encoded media bytes/sector	4,836
Original data bits/sector	16,384
Original data bytes/sector	2,048
Ratio of original to media data	2.36

Unlike CDs, DVDs do not use subcodes and instead use the ID bytes in each data frame to store the sector number and information about the sectors.

Handling Errors

DVDs use more powerful error correcting codes than were first devised for CDs. Unlike CDs, which have different levels of error correction depending on whether audio/video or data is being stored, DVDs treat all information equally and apply the full error correction to all sectors.

The main error correcting in DVDs takes place in the ECC frame. Parity outer (column) and parity inner (row) bits are added to detect and correct errors. The scheme is simple and yet very effective. The information from the data frames is first broken up into 192 rows of 172 bytes each. Then, a polynomial equation is used to calculate and add 10 PI bytes to each row, making the rows now 182 bytes each. Finally, another polynomial equation is used to calculate 16 PO (Parity Outer) bytes for each column, resulting in 16 bytes (rows) being added to each column. What started out as 192 rows of 172 bytes becomes 208 rows of 182 bytes with the PI and PO information added.

The function of the PI and PO bytes can be explained with a simple example using simple parity. In this example, 2 bytes are stored (01001110 = N, 01001111 = O). To add the error correcting information, they are organized in rows, as shown in the following:

	Data bits
	1 2 3 4 5 6 7 8
Byte 1	0 1 0 0 1 1 1 0
Byte 2	0 1 0 0 1 1 1 1

Then, 1 PI bit is added for each row, using odd parity. This means you count up the 1 bits: In the first row there are 4, so the parity bit is created as a 1, making the sum an odd number. In the second row, the parity bit is a 0 because the sum of the 1s was already an odd number. The result is as follows:

	Data bits	PI
	1 2 3 4 5 6 7 8	
Byte 1	0 1 0 0 1 1 1 0	1
Byte 2	0 1 0 0 1 1 1 1	0

Next, the parity bits for each column are added and calculated the same as before. In other words, the parity bit will be such that the sum of the 1s in each column is an odd number. The result is as follows:

	Data bits	PI
	1 2 3 4 5 6 7 8	
Byte 1	0 1 0 0 1 1 1 0	1
Byte 2	0 1 0 0 1 1 1 1	0
PO	1 1 1 1 1 1 1 0	1

Now the code is complete, and the extra bits are stored along with the data. So, instead of just the 2 bytes being stored, 11 addition bits are stored for error correction. When the data is read back, the error correction bit calculations are repeated and they're checked to see whether they are the same as before. To see how it works, let's change one of the data bits (due to a read error) and recalculate the error correcting bits as follows:

	Data bits		
	1 2 3 4 5 6 7 8		PI
Byte 1	0 1 0 0 1 0 1 0		0
Byte 2	0 1 0 0 1 1 1 1		0
PO	1 1 1 1 1 0 1 0		1

Now, when you compare the PI and PO bits you calculated after reading the data to what was originally stored, you see a change in the PI bit for byte (row) 1 and in the PO bit for bit (column) 6. This identifies the precise row and column where the error was, which is at byte 1 (row 1), bit 6 (column 6). That bit was read as a 0, and you now know it is wrong, so it must have been a 1. The error correction circuitry then simply changes it back to a 1 before passing it back to the system. As you can see, with some extra information added to each row and column, error correction codes can indeed detect and correct errors on-the-fly.

Besides the ECC frames, DVDs also scramble the data in the frames using a bit-shift technique and also interleave parts of the ECC frames when they are actually recorded on the disc. These schemes serve to store the data somewhat out of sequence, preventing a scratch from corrupting consecutive pieces of data.

DVD Capacity (Sides and Layers)

Four main types of DVD discs are available, categorized by whether they are single- or double-sided, and single- or dual-layered. They are designated as follows:

- *DVD-5 - 4.7GB Single-Side, Single-Layer.* A DVD-5 is constructed from two substrates bonded together with adhesive. One is stamped with a recorded layer (called Layer 0), and the other is blank. An aluminum coating typically is applied to the single recorded layer.
- *DVD-9 - 8.5GB Single-Side, Dual-Layer.* A DVD-9 is constructed of two stamped substrates bonded together to form two recorded layers for one side of the disc, along with a blank substrate for the other side. The outer stamped layer (0) is coated with a semitransparent gold coating to both reflect light if the laser is focused on it and pass light if the laser is focused on the layer below. A single laser is used to read both layers; only the focus of the laser is changed.
- *DVD-10 - 9.4GB Double-Side, Single-Layer.* A DVD-10 is constructed of two stamped substrates bonded together back to back. The recorded layer (Layer 0 on each side) usually is coated with aluminum. Note that these discs are double-sided; however, drives have a read laser only on the bottom, which means the disc must be removed and flipped to read the other side.
- *DVD-18 - 17.1GB Double-Side, Dual-Layer.* A DVD-18 combines both double layers and double sides. Two stamped layers form each side, and the substrate pairs are bonded back to back. The outer layers (Layer 0 on each side) are coated with semitransparent gold, whereas the inner layers (Layer 1 on each side) are coated with aluminum. The reflectivity of a single-layer disc is 45%–85%, and for a dual-layer disc the reflectivity is 18%–30%. The automatic gain control (AGC) circuitry in the drive compensates for the different reflective properties.

Figure 13.9 shows the construction of each of the DVD disc types.

Note that although Figure 13.9 shows two lasers reading the bottom of the dual-layer discs, in actual practice only one laser is used. Only the focus is changed to read the different layers.

Dual-layer discs can have the layers recorded in two ways: either OTP or parallel track path (PTP). OTP minimizes the time needed to switch from one layer to the other when reading the disc. When reaching the inside of the disc (end of Layer 0), the laser pickup remains in the same location—it merely moves toward the disc slightly to focus on Layer 1. When written in OTP mode, the lead-out zone toward the outer part of the disc is called a middle zone instead.

Discs written in PTP have both spiral layers written (and read) from the inside out. When changing from Layer 0 to Layer 1, PTP discs require the laser pickup to move from the outside (end of the first layer) back to the inside (start of the second layer), as well as for the focus of the laser to change. Virtually all discs are written in OTP mode to make the layer change quicker.

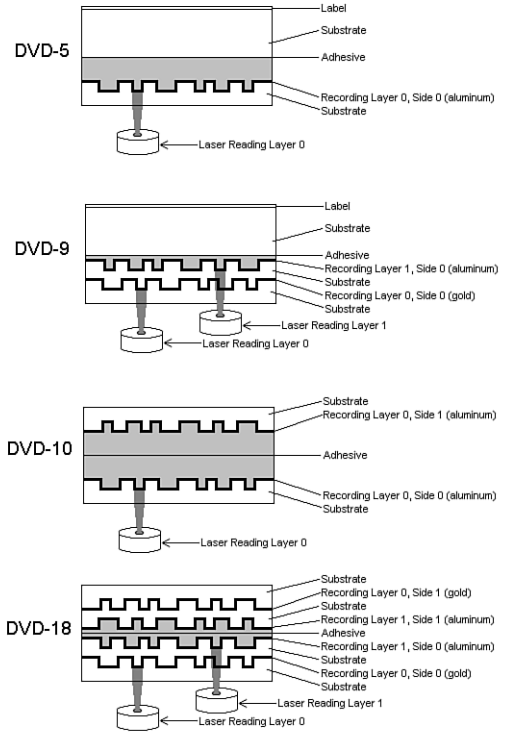

Figure 13.9 DVD disk types and construction.

To allow the layers to be read more easily even though they are on top of one another, discs written in PTP mode have the spiral direction changed from one layer to the other. Layer 0 has a spiral winding clockwise (which is read counterclockwise), whereas Layer 1 has a spiral winding counterclockwise. This typically requires that the drive spin the disc in the opposite direction to read that layer, but with OTP the spiral is read from the outside in on the second layer. So Layer 0 spirals from the inside out, and Layer 1 spirals from the outside in.

Figure 13.10 shows the differences between PTP and OTP on a DVD.

DVDs store up to 4.7GB–17.1 GB, depending on the type. Table 13.19 shows the precise capacities of the various types of DVDs.

Table 13.19 DVD Capacity

	Single-Layer	Dual-Layer
DVD Designation	DVD-5	DVD-9
B	4,695,853,056	8,535,691,264
KiB	4,585,794	8,335,636
KB	4,695,853	8,535,691
MiB	4,586	8,336
MB	4,696	8,536
GiB	4.6	8.3
GB	4.7	8.5
MPEG-2 video (approx. minutes)	133	242
MPEG-2 video (hours:minutes)	2:13	4:02
	Single-Layer Double-Sided	Dual-Layer Double-Sided
DVD Designation	DVD-10	DVD-18
B	9,391,706,112	17,071,382,528
KiB	9,171,588	16,671,272
KB	9,391,706	17,071,383
MiB	9,172	16,671
MB	9,392	17,071
GiB	9.2	16.7
GB	9.4	17.1
MPEG-2 video (approx. minutes)	266	484
MPEG-2 video (hours:minutes)	4:26	8:04

B = Byte (8 bits)
KiB = Kibibyte (1,024 bytes)
MiB = Mebibyte (1,048,576 bytes)
GiB = Gibibyte (1,073,741,824 bytes)
KB = Kilobyte (1,000 bytes)
MB = Megabyte (1,000,000 bytes)
GB = Gigabyte (1,000,000,000 bytes)

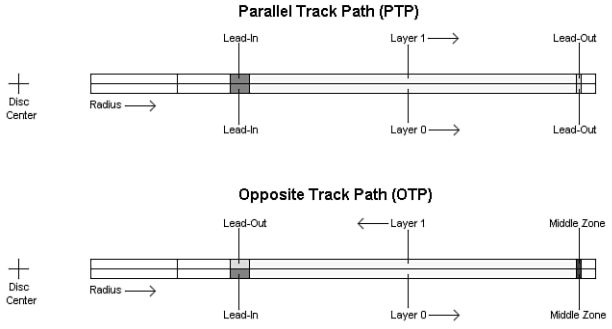

Figure 13.10 PTP versus OTP.

As you might notice, the capacity of dual-layer discs is slightly less than twice of single-layer discs, even though the layers take up the same space on the discs (the spiral tracks are the same length). This was done intentionally to improve the readability of both layers in a dual-layer configuration. To do this, the bit cell spacing was slightly increased, which increases the length of each pit and land. When reading a dual-layer disc, the drive spins slightly faster to compensate, resulting in the same data rate. However, because the distance on the track is covered more quickly, less overall data can be stored.

Besides the standard four capacities listed here, a double-sided disc with one layer on one side and two layers on the other can also be produced. This would be called a DVD-14 and have a capacity of 13.2GB, or about 6 hours and 15 minutes of MPEG-2 video. Additionally, 80mm discs, which store less data in each configuration than the standard 120mm discs, can be produced.

Because of the manufacturing difficulties and the extra expense of double-sided discs—and the fact that they must be ejected and flipped to play both sides—most DVDs are configured as either a DVD-5 (single-sided, single-layer) or a DVD-9 (single-sided, dual-layer), which allows up to 8.5GB of data or 242 minutes of uninterrupted MPEG-2 video to be played. The 133-minute capacity of DVD-5 video discs accommodates 95% or more of the movies ever made.

Data Encoding on the Disc

As with CDs, the pits and lands themselves do not determine the bits; instead, the transitions (changes in reflectivity) from pit to land and land to pit determine the actual bits on the disc. The disc track is divided into bit cells or time intervals (T), and a pit or land used to represent data is required to be a minimum of 3T or a maximum of 11T intervals (cells) long. A 3T long pit or land represents a 1001, and a 11T long pit or land represents a 100000000001.

Data is stored using eight to sixteen modulation, which is a modified version of the eight to fourteen modulation (EFM) used on CDs. Because of this, eight to sixteen modulation is sometimes called EFM+. This modulation takes each byte (8 bits) and converts it into a 16-bit value for storage. The 16-bit conversion codes are designed so that there are never less than 2 or more than 10 adjacent 0 bits (resulting in no less than 3 or no more than 11 time intervals between 1s). EFM+ is a form of RLL encoding called RLL 2,10 (RLL x,y where x = the minimum and y = the maximum run of 0s). This is designed to prevent long strings of 0s, which could more easily be misread due to clocks becoming out of sync, as well as to limit the minimum and maximum frequency of transitions actually placed

on the recording media. Unlike CDs, no merge bits exist between codes. The 16-bit modulation codes are designed so that they will not violate the RLL 2,10 form without needing merge bits. Because the EFM used on CDs really requires more than 17 bits for each byte (because of the added merge and sync bits), EFM+ is slightly more efficient since only slightly more than 16 bits are generated for each byte encoded.

Note that although no more than 10 0s are allowed in the modulation generated by EFM+, the sync bits added when physical sectors are written can have up to 13 0s, meaning a time period of up to 14T between 1s written on the disc and pits or lands up to 14T intervals or bit cells in length.

DVD Drive Speed

As with CDs, DVDs rotate counterclockwise (as viewed from the reading laser) and typically are recorded at a constant data rate called CLV. Therefore, the track (and thus the data) is always moving past the read laser at the same speed, which originally was defined as 3.49 meters per second (or 3.84m/sec on dual-layer discs). Because the track is a spiral that is wound more tightly near the center of the disc, the disc must spin at varying rates to maintain the same track linear speed. In other words, to maintain a CLV, the disk must spin more quickly when reading the inner track area and more slowly when reading the outer track area. The speed of rotation in a 1x drive (3.49 meters per second is considered 1x speed) varies from 1,515rpm when reading the start (inner part) of the track down to 570rpm when reading the end (outer part) of the track.

Single-speed (1x) DVD-ROM drives provide a data transfer rate of 1.385MB/second, which means the data transfer rate from a DVD-ROM at 1x speed is roughly equivalent to a 9x CD-ROM (1x CD-ROM data transfer rate is 153.6KB/s, or 0.1536MB/s). This does not mean, however, that a 1x DVD drive can read CDs at 9x rates: DVD drives actually spin at a rate that is just under three times faster than a CD-ROM drive of the same speed. So, a 1x DVD drive spins at about the same rotational speed as a 2.7x CD drive. Many DVD drives list two speeds, one for reading DVD discs and another for reading CD discs. For example, a DVD-ROM drive listed as a 16x/40x would indicate the performance when reading DVD/CD discs, respectively.

As with CDs, drive manufacturers began increasing the speeds of their drives by making them spin more quickly. A drive that spins twice as fast was called a 2x drive, a drive that spins four times as fast was 4x, and so on. At higher speeds, it became difficult to build motors that could change speeds (spin up or down) as quickly as needed when data was read from different parts of the disc. Because of this, faster DVD drives spin the disc at a fixed rotational, rather than linear speed. This is termed *constant angular velocity (CAV)* because the angular velocity (or rotational speed) remains a constant.

The faster drives are useful primarily for data, not video. Having a faster drive can reduce or eliminate the pause during layer changes when playing a DVD video disc, but having a faster drive has no effect on video quality.

DVD-ROM drives have been available in speeds up to 20x or more, but because virtually all are CAV, they actually achieve the rated transfer speed only when reading the outer part of a disc. Table 13.20 shows the data rates for DVD drives reading DVD discs and how that rate compares to a CD-ROM drive.

DVD Formats and Standards

As with the CD standards, the DVD standards are published in reference books produced mainly by the DVD forum, but also by other companies.

The DVD-Video and DVD-ROM standards are pretty well established, but recordable DVD technology is still evolving. The standards situation for recordable DVD is more confusing than usual, especially because there are at least four different (and somewhat incompatible) recording formats! It remains to be seen which will have the best support and become the most popular, but so far the DVD+RW format looks to be the most promising. At this point, the only type of recordable DVD I recommend for both home DVD recorders and PC-based DVD recordable drives are units that conform to the DVD+RW format. I recommend avoiding all others at the risk of owning an orphaned product.

The current standard DVD formats are shown in Table 13.21.

With advancements coming in blue-light lasers, this capacity will be increased several-fold in the future with a HD-DVD format that can store up to 20GB per layer. Prototype players have already been shown by major manufacturers, although you shouldn't expect to see HD-DVD on the market for several years.

DVD drives are fully backward-compatible and as such are capable of playing today's CD-ROMs as well as audio CDs. When playing existing CDs, the performance of current models is equivalent to a 40x or faster CD-ROM drive. Therefore, users who currently own slower CD-ROM drives might want to consider a DVD drive instead of upgrading to a faster CD-ROM drive. Several manufacturers have announced plans to phase out their CD-ROM drive products in favor of DVD. DVD is rapidly making CD-ROMs obsolete in the same way that audio CDs displaced vinyl records in the 1980s. The only thing keeping the CD-ROM format alive is the battle between competing DVD recordable standards and the fact that CD-R and CD-RW are rapidly becoming the de facto replacements for the floppy drive.

The current crop of DVD drives features several improvements over the first-generation models of 1997. Those units were expensive, slow, and incompatible with either CD-R or CD-RW media. Many early units asked your overworked video card to try to double as an MPEG decoder to display DVD movies, with mediocre results in speed and image quality. As is often the case with "leading-edge" devices, their deficiencies make them eminently avoidable.

Many PC vendors have integrated DVD-ROM drives into their new high-end computers, usually as an option. Originally, most of these installations included an MPEG-2 decoder board for processing the compressed video on DVD discs. This offloads the intensive MPEG calculations from the system processor and enables the display of full-screen, full-motion video on a PC. After processors crossed 400MHz in speed, performing MPEG-2 decoding reliably in software became possible, so any systems faster than that usually don't include a hardware decoder card.

Table 13.20 DVD Speeds and Transfer Rates

Column 1	Column 2	Column 3	Column 4	Column 5	Column 6
Advertised DVD-ROM Speed (Max. if CAV)	**Time to Read Single Layer DVD if CLV**	**Time to Read Dual Layer DVD if CLV**	**Transfer Rate (Bytes/sec) (Max. if CAV)**	**Actual DVD Speed Minimum if CAV**	**Minimum Transfer Rate if CAV (Bytes/sec)**
1x	56.5	51.4	1,384,615	0.4x	553,846
2x	28.3	25.7	2,769,231	0.8x	1,107,692
4x	14.1	12.8	5,538,462	1.7x	2,353,846
6x	9.4	8.6	8,307,692	2.5x	3,461,538
8x	7.1	6.4	11,076,923	3.3x	4,569,231
10x	5.7	5.1	13,846,154	4.1x	5,676,923
12x	4.7	4.3	16,615,385	5.0x	6,923,077
16x	3.5	3.2	22,153,846	6.6x	9,138,462
20x	2.8	2.6	27,692,308	8.3x	11,492,308
24x	2.4	2.1	33,230,769	9.9x	13,707,692
32x	1.8	1.6	44,307,692	13.2x	18,276,923
40x	1.4	1.3	55,384,615	16.6x	22,984,615
48x	1.2	1.1	66,461,538	19.9x	27,553,846
50x	1.1	1.0	69,230,769	20.7x	28,661,538

Column 1 indicates the advertised drive speed. This is a constant speed if the drive is CLV or a maximum speed only if CAV (most DVD-ROM drives are CAV).

Columns 2 and 3 indicate how long it would take to read a full disc (single- or dual-layer) if the drive were CLV. For CAV drives, those figures are longer because the average read speed is less than the advertised speed. The fourth column indicates the data transfer rate, which for CAV drives is a maximum figure seen only when reading the end of a disc.

Columns 4–8 indicate the actual minimum "x" speed for CAV drives, along with the minimum transfer speed (when reading the start of any disc) and an optimistic average speed (true only when reading a full disc; otherwise, it's even lower) in both "x" and byte-per-second formats.

Columns 9 and 10 indicate the maximum linear speeds the drive attains, in both meters per second and miles per hour. CLV drives maintain those speeds everywhere on the disc, whereas CAV drives reach those speeds only on the outer part of a disc.

Column 7	Column 8	Column 9	Column 10	Column 11	Column 12	Column 13
Average DVD Speed if CAV	Average Transfer Rate if CAV (Bytes/sec)	Maximum Linear Speed (m/sec)	Maximum Linear Speed (mph)	Single Layer Rot. Speed Min. if CLV Max. if CAV (rpm)	Single Layer Rot. Speed Max. if CLV (rpm)	Usual Transfer Rate When Reading CD-ROMs
0.7x	969,231	3.5	7.8	570	1,515	2.7x
1.4x	1,938,462	7.0	15.6	1,139	3,030	5.4x
2.9x	3,946,154	14.0	31.2	2,279	6,059	11x
4.3x	5,884,615	20.9	46.8	3,418	9,089	16x
5.7x	7,823,077	27.9	62.5	4,558	12,119	21x
7.1x	9,761,538	34.9	78.1	5,697	15,149	27x
8.5x	11,769,231	41.9	93.7	6,836	18,178	32x
11.3	15,646,154	55.8	124.9	9,115	24,238	43x
14.2	19,592,308	69.8	156.1	11,394	30,297	54x
17.0	23,469,231	83.8	187.4	13,673	36,357	64x
22.6	31,292,308	111.7	249.8	18,230	48,476	86x
28.3	39,184,615	139.6	312.3	22,788	60,595	107x
34.0	47,007,692	167.5	374.7	27,345	72,714	129x
35.4	48,946,154	174.5	390.3	28,485	75,743	134x

Columns 11 and 12 indicate the rotational speeds of a drive. The first of those shows how quickly the disc spins when reading the start of a disc. This applies to either CAV or CLV drives. For CAV drives, that figure is constant no matter where on the disc is being read. The second of those two columns shows the maximum rotational speed if the drive were a CLV type. Because most faster drives are CAV, those figures are mostly theoretical for the faster drives.

Column 13 shows the speed the drive would be rated if it were a CD-ROM drive. This is based on the rotational speed, not the transfer rate. In other words, a 12x DVD drive would perform as a 32x CD-ROM drive when reading CDs. Most DVD drives list their speeds when reading CDs in the specifications. Due to the use of PCAV (Partial CAV) designs, some might have higher CD performances than the table indicates.

Table 13.21 Standard DVD Formats and Capacities

Format	Disc Size	Sides	Layers	Data Capacity	Video Capacity
DVD-ROM Formats and Capacities					
DVD-5	120mm	Single	Single	4.7GB	2.2 hours
DVD-9	120mm	Single	Double	8.5GB	4.0 hours
DVD-10	120mm	Double	Single	9.4GB	4.4 hours
DVD-14	120mm	Double	Both	13.2GB	6.3 hours
DVD-18	120mm	Double	Double	17.1GB	8.1 hours
DVD-1	80mm	Single	Single	1.5GB	0.7 hours
DVD-2	80mm	Single	Double	2.7GB	1.3 hours
DVD-3	80mm	Double	Single	2.9GB	1.4 hours
DVD-4	80mm	Double	Double	5.3GB	2.5 hours
Recordable DVD Formats and Capacities					
DVD-R 1.0	120mm	Single	Single	3.95GB	N/A
DVD-R 2.0	120mm	Single	Single	4.7GB	N/A
DVD-RAM 1.0	120mm	Single	Single	2.58GB	N/A
DVD-RAM 1.0	120mm	Double	Single	5.16GB	N/A
DVD-RAM 2.0	120mm	Single	Single	4.7GB	N/A
DVD-RAM 2.0	120mm	Double	Single	9.4GB	N/A
DVD-RAM 2.0	80mm	Single	Single	1.46GB	N/A
DVD-RAM 2.0	80mm	Double	Single	2.65GB	N/A
DVD-RW 2.0	120mm	Single	Single	4.7GB	N/A
DVD+RW 2.0	120mm	Single	Single	4.7GB	N/A
DVD+RW 2.0	120mm	Double	Single	9.4GB	N/A
CD-ROM Formats and Capacities (for comparison)					
CD-ROM/R/RW	120mm	Single	Single	0.737GB	N/A
CD-ROM/R/RW	80mm	Single	Single	0.194GB	N/A

Some manufacturers of video display adapters have begun to include MPEG decoder hardware on their products. These adapters are known as "DVD MPEG-2 accelerated" and call for some of the MPEG decoding tasks to be performed by software. Any software decoding involved in an MPEG solution places a greater burden on the main system processor and can therefore yield less satisfactory results on slower systems.

DIVX (Discontinued Standard)

DIVX (Digital Video Express) was a short-lived proprietary DVD format developed by Digital Video Express (a Hollywood law firm) and Circuit City. It was discontinued on June 16, 1999, less than a year after it was released.

The name now lives on as an open encoding standard for DVD video. However, this encoding standard actually has no relation to the original DIVX format other than the name.

Note

More detailed coverage of DIVX is included in Chapter 13 of the 11th and 12th editions of this book, both of which are included in their entirety on the DVD accompanying this book.

DVD Drive Compatibility

When DVD drives first appeared on the market, they were touted to be fully backward-compatible with CD-ROM drives. Although that might be the case when reading commercially pressed CD-ROM discs, that was not necessarily true when reading CD-R or CD-RW media. Fortunately, the industry has responded with standards that let you know in advance how compatible your DVD drive will be. These standards are called *MultiRead* for computer-based drives and *MultiPlay* for consumer standalone devices, such as DVD-Video or CD-DA players. See the section "MultiRead Specifications," later in this chapter.

DVD Copy Protection

DVD video discs employ several levels of protection that are mainly controlled by the DVD Copy Control Association (DVD CCA) and a third-party company called Macrovision. This protection typically applies only to DVD-Video discs, not DVD-ROM software. So, for example, copy protection might affect your ability to make backup copies of *The Matrix*, but it won't affect a DVD encyclopedia or other software application distributed on DVD-ROM discs.

Note that every one of these protection systems has been broken, so with a little extra expense or the correct software, you can defeat the protection and make copies of your DVDs either to other digital media (hard drive, DVD+RW, CD-R/RW, and so on) or analog media (such as a VHS or other tape format).

A lot of time and money are wasted on these protection schemes, which can't really foil the professional bootleggers willing to spend the time and money to work around them. But they can make it difficult for the average person to legitimately back up his expensive media.

The three main protection systems used with DVD-Video discs are

- Regional Playback Control (RPC)
- Content Scrambling System (CSS)
- Analog Protection System (APS)

Regional Playback Control

Regional playback was designed to allow discs sold in specific geographical regions of the world to play only on players sold in those same regions. The idea was to allow a movie to be released at different times in different parts of the world and to prevent people from ordering discs from regions in which the movie had not been released yet.

Eight regions are defined in the RPC standard. Discs (and players) usually are identified by a small logo or label showing the region number superimposed on a world globe. Multiregion discs are possible, as are discs that are not region locked. If a disc plays in more than one region, it has more than one number on the globe. The regions are

- United States, Canada, U.S. Territories
- Japan, Europe, South Africa, and the Middle East
- Southeast Asia and East Asia

- Australia, New Zealand, Pacific Islands, Central America, Mexico, South America, and the Caribbean
- Eastern Europe, Indian subcontinent, Africa, North Korea, and Mongolia
- China
- Reserved
- Special international or mobile venues, such as airplanes, cruise ships, and so on

The region code is embedded in the hardware of DVD video players. Most players are preset for a specific region and can't be changed. Some companies who sell the players modify them to play discs from all regions; these are called *region-free* or *code-free* players. Some newer discs have an added region code enhancement (RCE) function that checks to see whether the player is configured for multiple or all regions and then, if it is, refuses to play. Most newer region-free modified players know how to query the disc first to circumvent this check as well.

DVD-ROM drives used in PCs originally did not have RPC in the hardware, placing that responsibility instead on the software used to play DVD video discs on the PC. The player software would usually lock the region code to the first disc that was played and then from that point on, play only discs from that region. Reinstalling the software enabled the region code to be reset, and numerous patches were posted on Web sites to enable resetting the region code even without reinstalling the software. Because of the relative ease of defeating the region-coding restrictions with DVD-ROM drives, starting on January 1, 2000, all DVD-ROM drives were required to have RPC-II, which embeds the region coding directly into the drive.

RPC-II (or RPC-2) places the region lock in the drive, and not in the playing or MPEG-2 decoding software. You can set the region code in RPC-II drives up to five times total, which basically means you can change it up to four times after the initial setting. Usually, the change can be made using the player software you are using, or you can download region change software from the drive manufacturer. Upon making the fourth change (which is the fifth setting), the drive is locked on the last region set.

Content Scramble System

The Content Scramble System (CSS) provides the main protection for DVD-Video discs. It wasn't until this protection was implemented that the Motion Picture Association of America (MPAA) agreed to release movies in the DVD format, which is the main reason the rollout of DVD had been significantly delayed.

CSS originally was developed by Matsushita (Panasonic) and is used to digitally scramble and encrypt the audio and video data on a DVD-Video disc. Descrambling requires a pair of 40-bit (5-byte) keys (numeric codes). One of the keys is unique to the disc, whereas the other is unique to the video title set (VTS file) being descrambled. The disc and title keys are stored in the lead-in area of the disc in an encrypted form. The CSS scrambling and key writing are carried out during the glass mastering procedure, which is part of the disc manufacturing process.

You can see this encryption in action if you put a DVD disc into a DVD-ROM drive on a PC, copy the files to your hard drive, and then try to view the files. The files are usually called `VTS_`*`xx`*`_`*`yy`*`.VOB` (video object), where *xx* represents the title number and *yy* represents the section number. Typically, all the files for a given movie have the same title number and the movie is spread out among several 1GB or smaller files with different section numbers. These .VOB files contain both the encrypted video and audio streams for the movie interleaved together. Other files with a .IFO extension contain information used by the DVD player to decode the video and audio streams in the .VOB files. If you copy the .VOB and .IFO files onto your hard drive and try to click or play the .VOB files directly, you

either see and hear scrambled video and audio or receive an error message about playing copy-protected files.

This encryption is not a problem if you use a CSS-licensed player (either hardware or software) and play the files directly from the DVD disc. All DVD players, whether they are consumer standalone units or software players on your PC, have their own unique CSS unlock key assigned to them. Every DVD video disc has 400 of these 5-byte keys stamped onto the disc in the lead-in area (which is not usually accessible by programs) on the DVD in encrypted form. The decryption routine in the player uses its unique code to retrieve and unencrypt the disc key, which is then used to retrieve and unencrypt the title keys. CSS is essentially a three-level encryption that originally was thought to be very secure but has proven otherwise.

In October 1999, a 16-year-old Norwegian programmer was able to extract the first key from one of the commercial PC-based players, which allowed him to very easily decrypt disc and title keys. A now famous program called DeCSS was then written that can break the CSS protection on any DVD video title and save unencrypted .VOB files to a hard disk that can be played by any MPEG-2 decoder program. Needless to say, this utility (and others based on it) has been the cause of much concern in the movie industry and has caused many legal battles over the distribution and even links to this code on the Web. Do a search on DeCSS for some interesting legal reading.

As if that weren't enough, in March 2001, two MIT students published an incredibly short (only seven lines long!) and simple program that can unscramble CSS so quickly that a movie can essentially be unscrambled in real-time while it is playing. They wrote and demonstrated the code as part of a two-day seminar they conducted on the controversial Digital Millennium Copyright Act, illustrating how trivial the CSS protection really is.

Because of the failure of CSS, the DVD forum is now actively looking into other means of protection, especially including digital watermarks, which consists essentially of digital noise buried into the data stream, which is supposed to be invisible to normal viewing. Unfortunately, when similar technology was applied to DIVX (the discontinued proprietary DVD standard), these watermarks caused a slight impairment of the image—a raindrop or bullet-hole effect could be seen by some in the picture. Watermarks also might require new equipment to play the discs.

Analog Protection System

APS (also called CopyGuard by Macrovision) is an analog protection system developed by Macrovision and is designed to prevent making VCR tapes of DVD-Video discs. APS requires codes to be added to the disc, as well as special modifications in the player. APS starts with the creation or mastering of a DVD, where APS is enabled by setting predefined control codes in the recording. During playback in an APS-enabled (Macrovision-enabled) player, the digital-to-analog converter (DAC) chip inside the player adds the APS signals to the analog output signal being sent to the screen. These additions to the signal are designed so that they are invisible when viewed on a television or monitor but cause copies made on most VCRs to appear distorted. Unfortunately, some TVs or other displays can react to the distortions added to create a less-than-optimum picture.

APS uses two signal modifications called automatic gain control and colorstripe. The automatic gain control process consists of pulses placed in the vertical scan interval of the video signal, which TVs can't detect but which cause dim and noisy pictures, loss of color, loss of video, tearing, and so on on a VCR. This process has been used since 1985 on many prerecorded video tapes to prevent copying. The colorstripe process modifies colorburst information that is also transparent on television displays but produces lines across the picture when recorded on a VCR.

Note that many older players don't have the licensed Macrovision circuits and simply ignore the code to turn on the APS signal modifications. Also, various image stabilizer, enhancer, or copyguard

decoder units are available that can plug in between the player and VCR to remove the APS copy-guard signal and allow a perfect recording to be made.

CD/DVD Drives and Specifications

When evaluating a CD or DVD drive for your PC, you should consider three distinct sets of criteria, as follows:

- The drive's performance specifications
- The interface the drive requires for connection to your PC
- The physical disc-handling system the drive uses

These criteria will affect how fast the drive operates, how it is connected to your system, and how convenient (or inconvenient) it is to use.

Performance Specifications

Many factors in a drive can affect performance, and several specifications are involved. Typical performance figures published by manufacturers are the data transfer rate, the access time, the internal cache or buffers (if any), and the interface the drive uses. The following sections examine these specifications.

Data Transfer Rate

The data transfer rate tells you how quickly the drive can read from the disc and transfer to the host computer. Normally, transfer rates indicate the drive's capability for reading large, sequential streams of data.

Transfer speed is measured two ways. The one most commonly quoted with CD/DVD drives is the "x" speed, which is defined as a multiple of the particular standard base rate. For example, CD-ROM drives transfer at 153.6KB/sec according to the original standard. Drives that transfer twice that are 2x, 40 times that are 40x, and so on. DVD drives transfer at 1,385KB/sec at the base rate, whereas drives that are 20 times faster than that are listed as 20x. Note that because almost all faster drives feature CAV, the "x" speed usually indicated is a maximum that is seen only when reading data near the outside (end) of a disc. The speed near the beginning of the disc might be as little as half that, and of course, average speeds are somewhere in the middle.

With recordable CD drives, the speed is reported for various modes. CD-R drives have two speeds listed (one for writing, the other for reading), CD-RW drives have three, and CD-RW/DVD-ROM drives have four. On a CD-RW drive, the speeds are in the form A/B/C, where A is the speed when writing CD-Rs, B is the speed when writing CD-RWs, and C is the speed when reading. The first CD-RW drive on the market was 2/2/6, with versions up to 40/12/40 available today. CD-RW/DVD-ROM drives use the format A/B/C-D, where the fourth number represents the DVD-ROM reading speed. Some of the fastest CD-RW/DVD-ROM drives today report 20/10/40-12.

See the previous sections "CD Drive Speed" and "DVD Drive Speed," earlier in this chapter, for more information about speeds and transfer rates.

Access Time

The access time for a CD or DVD drive is measured the same way as for PC hard disk drives. In other words, the access time is the delay between the drive receiving the command to read and its actual first reading of a bit of data. The time is recorded in milliseconds; a typical manufacturer's rating would be listed as 95ms. This is an average access rate; the true access rate depends entirely on where the data is located on the disc. When the read mechanism is positioned to a portion of the disc nearer

to the narrower center, the access rate is faster than when it is positioned at the wider outer perimeter. Access rates quoted by many manufacturers are an average taken by calculating a series of random reads from a disc.

Obviously, a faster (that is, a lower) average access rate is desirable, especially when you rely on the drive to locate and pull up data quickly. Access times for CD and DVD drives have been steadily improving, and the advancements are discussed later in this chapter. Note that these average times are significantly slower than PC hard drives, ranging from 200ms to below 100ms, compared to the 8ms access time of a typical hard disk drive. Most of the speed difference lies in the construction of the drive itself. Hard drives have multiple-read heads that range over a smaller surface area of the medium; CD/DVD drives have only one laser pickup, and it must be capable of accessing the entire range of the disc. In addition, the data on a CD is organized in a single long spiral. When the drive positions its head to read a track, it must estimate the distance into the disc and skip forward or backward to the appropriate point in the spiral. Reading off the outer edge requires a longer access time than the inner segments, unless you have a CAV drive, which spins at a constant rate so the access time to the outer tracks is equal to that of the inner tracks.

Access times have fallen a great deal since the original single-speed drives came out. However, recently a plateau seems to have been reached with most CD/DVD drives hovering right around the 100ms area, with some as low as 80ms. With each increase in data transfer speed, you usually see an improvement in access time as well. But as you can see in Table 13.22, these improvements are much less significant because of the physical limitation of the drive's single-read mechanism design.

Table 13.22 Typical CD-ROM Drive Access Times

Drive Speed	Access Time (ms)
1x	400
2x	300
3x	200
4x	150
6x	150
8x–12x	100
16x–24x	90
32x–52x or greater	85 or less

The times listed here are typical examples for good drives; within each speed category some drives are faster and some are slower. Because of the additional positioning accuracy required and the overall longer track, DVD drives usually report two access speeds—one when reading DVDs and the other when reading CDs. The DVD access times typically run 10ms–20ms slower than when reading CDs.

Buffer/Cache

Most CD/DVD drives include internal buffers or caches of memory installed onboard. These buffers are actual memory chips installed on the drive's circuit board that enable it to stage or store data in larger segments before sending it to the PC. A typical buffer for a CD/DVD drive is 128KB, although drives are available that have either more or less (more is usually better). Recordable CD or DVD drives typically have much larger buffers of 2MB–4MB or more to prevent buffer underrun problems and to smooth writing operations. Generally, faster drives come with more buffer memory to handle the higher transfer rates.

Having buffer or cache memory for the CD/DVD drive offers a number of advantages. Buffers can ensure that the PC receives data at a constant rate; when an application requests data from the drive, the data can be found in files scattered across different segments of the disc. Because the drive has a relatively slow access time, the pauses between data reads can cause a drive to send data to the PC sporadically. You might not notice this in typical text applications, but on a drive with a slower access rate coupled with no data buffering, it is very noticeable—and even irritating—during the display of video or some audio segments. In addition, a drive's buffer, when under the control of sophisticated software, can read and have ready the disc's table of contents, speeding up the first request for data. A minimum size of 128KB for a built-in buffer or cache is recommended and is standard on many 24x and faster drives. For greater performance, look for drives with 256KB or larger buffers.

CPU Utilization

A once-neglected but very real issue in calculating computer performance is the impact that any piece of hardware or software has on the central processing unit (CPU). This "CPU utilization" factor refers to how much attention the CPU (such as Pentium III/4, Athlon, and so on) must provide to the hardware or software to help it work. A low CPU utilization percentage score is desirable because the less time a CPU spends on any given hardware or software process, the more time it has for other tasks and thus the greater the performance for your system. On CD-ROM drives, three factors influence CPU utilization: drive speed, drive buffer size, and interface type.

Drive buffer size can influence CPU utilization. For CD-ROM drives with similar performance ratings, the drive with a larger buffer is likely to require less CPU time (lower CPU utilization percentage) than the one with a smaller buffer.

Because drive speed and buffer size are more of a given, the most important factor influencing CPU utilization is the interface type. Traditionally, SCSI-interface CD-ROM drives have had far lower CPU utilization rates than ATAPI drives of similar ratings. One review of 12x drives done several years ago rated CPU utilization for ATAPI CD-ROM drives at 65%–80%, whereas SCSI CD-ROM drives checked in at less than 11%. By using DMA or Ultra-DMA modes with an ATA interface drive, near-SCSI levels of low CPU utilization can be realized. Using DMA or Ultra-DMA modes can cut CPU utilization down to the 10% or lower range, leaving the CPU free to run applications and other functions.

Direct Memory Access and Ultra-DMA

Busmastering ATA controllers use Direct Memory Access (DMA) or Ultra-DMA transfers to improve performance and reduce CPU utilization. Virtually all modern ATA drives support Ultra-DMA. With busmastering, CPU utilization for ATA/ATAPI and SCSI CD-ROM drives is about equal at around 11%. Thus, it's to your benefit to enable DMA access for your CD-ROM drives (and your ATA hard drives, too) if your system permits it.

Most recent ATA/ATAPI CD-ROM drives (12x and above) support DMA or Ultra-DMA transfers, as does Windows 95B and above and most recent Pentium-class motherboards. To determine whether your Win9x, Me, or XP system has this feature enabled, check the System Properties' Device Manager tab and click the + mark next to Hard Disk Controllers. A drive interface capable of handling DMA transfers lists "Bus Master" in the name. Next, check the hard drive and CD-ROM information for your system. You can use the properties sheet for your system's CD-ROM drives under Windows 9x/Me and Windows 2000/XP to find this information; you might need to open the system to determine your hard drive brand and model. Hard disk drives and CD-ROM drives that support MultiWord DMA Mode 2 (16.6MB/sec), UltraDMA Mode 2 (33MB/sec), UltraDMA Mode 4 (66MB/sec), or faster can use DMA transfers. Check your product literature or the manufacturer's Web site for information.

To enable DMA transfers if your motherboard and drives support it, open the System Properties sheet in Windows 9x or later, click the Device Manager tab, and open the Properties sheet for your hard drive. Click the Settings tab, and place a check mark in the box labeled DMA.

Repeat the same steps to enable DMA transfers for any additional hard drives and ATAPI CD-ROM drives in your computer. Restart your computer after making these changes.

Note

I strongly recommend that you back up your drives and your Windows 9x Registry before you enable DMA support or before you install and enable the driver to allow DMA support. If your system hangs after you enable this feature, you must restart the system in Safe mode and uncheck the DMA box. In some cases, if you can't access safe mode, you might have to replace the Registry with the pre-DMA-enabled copy you saved. Otherwise, you'll be faced with editing Registry keys by hand to start your system again. Because DMA transfers bypass the CPU to achieve greater speed, DMA problems could result in data loss. Make backups first, instead of wishing you had later.

Also, if your drive supports any of the Ultra-DMA (also called Ultra-ATA) modes, you should upgrade your ATA cables to the 80-conductor style. Using these cables prevents noise and signal distortion that will occur if you try to use a standard 40-conductor cable with the Ultra-DMA modes. Most drives and motherboards refuse to enable Ultra-DMA modes faster than 33MB/sec if an 80-conductor cable is not detected.

Drive interfaces that don't mention busmastering either can't perform this speedup or need to have the correct driver installed. In some cases, depending on your Windows version and when your motherboard chipset was made, you must install chipset drivers to enable Windows to properly recognize the chipset and enable DMA modes. A good Web site for both Intel and non-Intel chipset support of this important feature is `www.bmdrivers.com`. Follow the links at this site to the motherboard chipset vendors, their technical notes (to determine whether your chipset supports busmastering), and the drivers you need to download. Virtually all motherboard chipsets produced since 1995 provide busmaster ATA support. Most of those produced since 1997 also provide UltraDMA support for up to 33MHz (Ultra-ATA/33) or 66MHz (Ultra-ATA/66) speed operation. Still, you should make sure that DMA is enabled to ensure you are benefiting from the performance it offers. Enabling DMA can dramatically improve DVD performance, for example.

Interface

The drive's interface is the physical connection of the drive to the PC's expansion bus. The interface is the data pipeline from the drive to the computer, and its importance shouldn't be minimized. Five types of interfaces are available for attaching a CD-ROM, CD-R, or CD-RW drive to your system:

- SCSI/ASPI (Small Computer System Interface/Advanced SCSI Programming Interface)
- ATA/ATAPI (AT Attachment/AT Attachment Packet Interface)
- Parallel port
- USB port
- FireWire (IEEE-1394)

The following sections examine these interface choices.

SCSI/ASPI

SCSI (pronounced *scuzzy*), or the Small Computer System Interface, is a name given to a special interface bus that allows many types of peripherals to communicate.

A standard software interface called ASPI (Advanced SCSI Programming Interface) enables CD-ROM drives (and other SCSI peripherals) to communicate with the SCSI host adapter installed in the computer. SCSI offers the greatest flexibility and performance of the interfaces available for CD-ROM drives and can be used to connect many other types of peripherals to your system as well.

The SCSI bus enables computer users to string a group of devices along a chain from one SCSI host adapter, avoiding the complication of installing a separate adapter card into the PC bus slots for each new hardware device, such as a tape unit or additional CD-ROM drive added to the system. These traits make the SCSI interface preferable for connecting a peripheral such as a CD-ROM to your PC.

Not all SCSI adapters are created equal, however. Although they might share a common command set, they can implement these commands differently, depending on how the adapter's manufacturer designed the hardware. ASPI was created to eliminate these incompatibilities. ASPI was originally developed by Adaptec, Inc., a leader in the development of SCSI controller cards and adapters who originally named it the Adaptec SCSI Programming Interface before it became a de facto standard. ASPI consists of two main parts. The primary part is an ASPI-Manager program, which is a driver that functions between the operating system and the specific SCSI host adapter. The ASPI-Manager sets up the ASPI interface to the SCSI bus.

The second part of an ASPI system is the individual ASPI device drivers. For example, you would get an ASPI driver for your SCSI CD-ROM drive. You can also get ASPI drivers for your other SCSI peripherals, such as tape drives and scanners. The ASPI driver for the peripheral talks to the ASPI-Manager for the host adapter. This is what enables the devices to communicate together on the SCSI bus.

The bottom line is that if you are getting a SCSI interface CD-ROM, be sure it includes an ASPI driver that runs under your particular operating system. Also, be sure that your SCSI host adapter has the corresponding ASPI-Manager driver as well. Substantial differences exist between SCSI adapters because SCSI can be used for a wide variety of peripherals. Low-cost, SCSI-3-compliant ISA or PCI adapters can be used for CD-ROM interfacing. In contrast, higher-performance PCI adapters that support more advanced SCSI standards, such as Wide, Ultra, UltraWide, Ultra2Wide, and so on, can be used with both CD-ROM drives and other devices, such as CD-R/CD-RW drives, hard drives, scanners, and tape backups. To help you choose the appropriate SCSI adapter for both your CD-ROM drive and any other SCSI-based peripheral you're considering, visit Adaptec's Web site.

The SCSI interface offers the most powerful and flexible connection for CD-ROMs and other devices. It provides better performance, and seven or more drives can be connected to a single host adapter. The drawback is cost. If you do not need SCSI for other peripherals and intend to connect only one CD-ROM drive to the system, you will be spending a lot of money on unused potential. In that case, an ATAPI interface CD-ROM drive is a more cost-effective choice.

◀◀ See "Small Computer System Interface," p. 538.

ATA/ATAPI

The ATA/ATAPI (AT Attachment/AT Attachment Packet Interface) is an extension of the same ATA (AT Attachment) interface most computers use to connect to their hard disk drives. ATA is sometimes also referred to as IDE (Integrated Drive Electronics). ATAPI is an industry-standard ATA interface used for CD/DVD and other drives. ATAPI is a software interface that adapts the SCSI/ASPI commands to the ATA interface. This enables drive manufacturers to take their high-end CD/DVD drive products and quickly adapt them to the ATA interface. This also enables the ATA drives to remain compatible with the Extensions that provide the CD/DVD drive with a software interface with DOS. With Windows 9x and later, the CD-ROM extensions are contained in the CD file system (CDFS) VxD (virtual device) driver.

ATA/ATAPI drives are sometimes also called enhanced IDE (EIDE) drives because this is an extension of the original IDE (technically the ATA) interface. In most cases, an ATA drive connects to the system via a second ATA interface connector and channel, leaving the primary one for hard disk drives only. This is preferable because ATA does not share the single channel well and would cause a hard disk drive to wait for CD/DVD commands to complete and vice versa. SCSI does not have this problem

because a SCSI host adapter can send commands to different devices without having to wait for each previous command to complete.

The ATA interface represents the most cost-effective and high-performance interface for CD-ROM drives. Most new systems that include a CD and/or DVD drive have it connected through ATA. You can connect up to two drives to the secondary ATA connector; for more than that, SCSI is your only choice and provides better performance as well.

Many systems on the market today can use the ATA/ATAPI CD/DVD drive as a bootable device, which allows the vendor to supply a recovery CD that can restore the computer's software to its factory-shipped condition. Later, you'll see how bootable CDs differ from ordinary CDs and how you can use low-cost CD-R/CD-RW drives, along with mastering and imaging software to make your own bootable CDs with your own preferred configuration.

◀◀ See "ATA Standards," p. 496.

▶▶ See "Creating a Bootable Floppy with CD-ROM Support," p. 806.

Parallel Port

In the past, some external CD-ROM or CD-RW drives were available in versions that connected to a PC's parallel port. USB has for the most part replaced the parallel port for this type of use.

If you use a parallel port drive, for best performance you should set your printer port to use IEEE-1284 standards, such as ECP/EPP or ECP, before connecting your parallel-port CD-ROM. These are bidirectional, high-speed extensions to the normal Centronics parallel port standard and provide better performance for virtually any recent parallel device. If your operating system supports Plug and Play (PnP) (such as Windows 9x/Me or 2000/XP does), simply plugging a PnP drive into the parallel port enables the OS to detect the new hardware and load the appropriate driver automatically.

▶▶ See "IEEE-1284 Parallel Port Standard," p. 986.

Note

Parallel port CD-ROM drives nearly always include a cable with a pass-through connector. This connector plugs into the parallel port and, if necessary, a printer cable can plug into the connector. This enables you to continue using the port to connect to your printer while sharing the interface with the CD-ROM drive. Note there might be performance problems when trying to print and read from the drive at the same time.

With the popularity, performance, and ease of use of USB, I recommend a USB external drive over a parallel port version. USB drives are much faster, more compatible, and easier to install and use.

USB Interface

Universal Serial Bus (USB) has proven to be extremely flexible and has been used for everything from keyboards and joysticks to CD/DVD drives from several vendors.

USB 1.1 and earlier drives provide read and write transfer rates that match the fastest rates possible with IEEE-1284 parallel ports, with read rates on typical 6x models ranging from 1,145KB/sec to 1,200KB/sec. USB 2.0 and later provide a transfer rate up to 60MB/sec, which is 40 times faster than USB 1.1 and yet is fully backward-compatible.

USB also provides benefits that no parallel port drive can match: for example, hot-swappability, which is the capability to be plugged in or unplugged without removing the power or rebooting the system. Additionally, USB devices are fully Plug and Play, allowing the device to be automatically recognized by the system and the drivers automatically installed.

For Windows 98/Me or Windows 2000/XP systems with USB ports, USB-based CD-RW drives are an excellent solution for backup and archiving of data onto low-cost, durable optical media.

FireWire

In addition, external CD/DVD drives are now available on the market with a FireWire (also called IEEE-1394 or iLink) interface. FireWire is a high-performance external interface designed mainly for video use. It evolved as an Apple standard and is used primarily on Macintosh systems. Because few PCs include FireWire ports as a standard item—whereas all PCs include USB—I usually recommend the more universally supported USB for external CD/DVD drives. Make sure any external drives you purchase use the faster USB 2.0 (also known as Hi-Speed USB), which is faster and far more readily available than FireWire versions. FireWire drives can be useful if you work in a two-platform environment (both PCs and Macs). However, because most Macs also support USB (and you can easily add a USB interface to those that don't), if your primary platform is the PC, I'd still recommend USB over FireWire.

If you do want to use a FireWire drive and your system does not include FireWire integrated into the motherboard, you can easily add a FireWire interface card to your PC. Additionally, some video and sound cards are available with FireWire ports as an option.

▶▶ See "USB and IEEE-1394 (i.Link or FireWire)," p. 962.

Loading Mechanism

Three distinctly different mechanisms exist for loading a disc into a CD/DVD drive: the tray, caddy, and slot. Each one offers some benefits and features. Which type you select has a major impact on your use of the drive because you interact with this mechanism every time you load a disc.

Some drives on the market allow you to insert more than one disc at a time. Some of these use a special cartridge that you fill with discs, much like multidisc CD changers used in automobiles. Newer models are slot-loading, allowing you to push a button to select which internal cartridge slot you want to load with a CD/DVD. The drive's door opens and you slide in the CD, which the drive mechanism grabs and pulls into place. Typical capacities range from three to six discs or more, and these are available in both SCSI and ATA interfaces.

Tray

Most current SCSI and ATAPI CD/DVD drives use a tray-loading mechanism. This is similar to the mechanism used with a stereo system. Because you don't need to put each disc into a separate caddy, this mechanism is much less expensive overall. However, it also means that you must handle each disc every time you insert or remove it.

Tray loading is less expensive than a caddy system (see the section, "Caddy," later in this chapter) because you don't need a caddy. It is also more convenient, unless you have caddies for all your discs. However, this can make it much more difficult for young children or those who work in harsh environments to use the discs without smudging or damaging them due to excess handling.

The tray loader itself is also subject to damage. The trays can easily break if bumped or if something is dropped on them while they are extended. Also, any contamination you place on the tray or disc is brought right into the drive when the tray is retracted. Tray-loaded drives should not be used in a harsh environment, such as a commercial or an industrial application. Make sure both the tray and the data surface of the disc are clean whenever you use a tray-loading drive.

The tray mechanism also does not hold the disc as securely as the caddy. If you don't have the disc placed in the tray properly when it retracts, the disc or tray can be damaged. Even a slight misalignment can prevent the drive from reading the disc properly, forcing you to open the tray and reset the disc.

Some tray drives can't operate in a vertical (sideways) position because gravity prevents proper loading and operation. Check to see whether the drive tray has retaining clips that grab the hub of the disc or tabs that fold in or flip over from the outside of the tray to retain the disc. If so, you can run the drive in either a horizontal or vertical position.

The main advantage of the tray mechanism over the others is in cost, and that is a big factor. Most drives today use the tray mechanism for handling discs.

Caddy

At one time, the caddy system was used on most high-end CD-ROM drives as well as the early CD-R and DVD-RAM drives. The caddy system requires that you place the disc itself into a special caddy, which is a sealed container with a metal shutter. The caddy has a hinged lid you open to insert the disc, but after that the lid remains shut. When you insert the caddy containing the disc into the drive, the drive opens a metal shutter on the bottom of the caddy, allowing access to the disc by the laser.

The caddy either is or is not the most convenient loading mechanism, depending on your point of view. If all your discs are in their own caddies, it is definitely the easiest and most convenient type to use. All you have to do is grab the caddy containing the disc you want and insert it into the drive. This makes the drive operate similar to a 3 1/2" floppy disk. You can handle the caddy without worrying about touching or contaminating the disc or the drive, making this the most accurate and durable mechanism as well. Young children can easily handle the caddies and don't have to touch the compact discs themselves.

Because the caddy is sealed, the discs are protected from damage caused by handling. The only time you actually handle the disc is when you first put it into the caddy. The caddy loading system also ensures that the disc is properly located when inside the drive. This allows for more accurate laser-head positioning mechanisms, and caddy drives generally have faster access times.

The drawbacks to the caddy system are the expense and the inconvenience of having to put the discs into the caddies. You get only one caddy with the drive, so if you want to store your discs in their own caddies, you must buy many more. Additional caddies can cost $4–$10 each, which can lead to a significant expense if you have a large number of discs.

The best application for caddy drives is in severe environments such as machine shops, repair shops, factories, or anywhere somebody with dirty hands or gloves on will have to change discs.

When DVD-RAM was first introduced, the disc had to remain in a caddy because the recordable surface is delicate. Since then, DVD-RAM drives have been made caddy-less, but especially with double-sided discs the information is at risk every time you handle the disc. Because of this fragility, as well as the general incompatibility of DVD-RAM with DVD-ROM, I recommend DVD+RW as the best solution for recordable DVD. No caddy is required with DVD+RW, and the format is fully two-way compatible with DVD-Video and DVD-ROM.

The caddy-loading system has declined in popularity because of the convenience of the tray. Today only a few drives on the market use caddies, and they are generally not for mainstream use (most have a SCSI interface, for example).

Slot

Some drives now use a slot-loading mechanism, identical to that used in most automotive CD players. This is very convenient because you just slip the disc into the slot, where the mechanism grabs it and draws it inside. Some drives can load several CDs at a time this way, holding them internally inside the drive and switching discs as access is required.

The primary drawback to this type of mechanism is that if a jam occurs, it can be much more difficult to repair because you might have to remove the drive to free the disc. Another drawback is that slot-loading drives usually can't handle the smaller 80mm discs, card-shaped discs or other modified disc physical formats or shapes.

Other Drive Features

Although drive specifications are of the utmost importance, you should also consider other factors and features when evaluating CD-ROM drives. Besides quality of construction, the following criteria bear scrutiny when making a purchasing decision:

- Drive sealing
- Self-cleaning lenses
- Internal versus external drive

Drive Sealing

Dirt is your CD/DVD drive's biggest enemy. Dust or dirt, when it collects on the lens portion of the mechanism, can cause read errors or severe performance loss. Many manufacturers seal off the lens and internal components from the drive bay in airtight enclosures. Other drives, although not sealed, have double dust doors—one external and one internal—to keep dust from the inside of the drive. All these features help prolong the life of your drive.

Some drives are sealed, which means no air flows through the chamber in which the laser and lens reside. Always look for sealed drives in harsh industrial or commercial environments. In a standard office or home environment, it is probably not worth the extra expense.

Self-Cleaning Lenses

If the laser lens gets dirty, so does your data. The drive will spend a great deal of time seeking and reseeking or will finally give up. Lens-cleaning discs are available, but built-in cleaning mechanisms are now included on virtually all good-quality drives. This might be a feature you'll want to consider, particularly if you work in a less-than-pristine work environment or have trouble keeping your desk clean, let alone your drive laser lens. You can clean the lens manually, but it is generally a delicate operation requiring that you partially disassemble the drive. Also, damaging the lens mechanism by using too much force is pretty easy to do. Because of the risks involved, in most cases I do not recommend the average person disassemble and try to manually clean the laser lens.

Internal Versus External Drives

When deciding whether you want an internal or external drive, think about where and how you're going to use your drive. What about the future expansion of your system? Both types of drives have advantages and disadvantages, such as the following:

- *External enclosure.* These tend to be rugged, portable, and large—in comparison to their internal versions. External drives are ideal for sharing a drive with multiple systems or especially with laptops or notebook portable systems. Parallel port drives are very portable and supported on a broad range of machines, but USB drives are a better choice for Windows 98 or later systems that have USB ports.

  SCSI drives are also ideal for external configurations because performance is even better than with internal ATA drives. If each PC has its own SCSI adapter with an external connection, all you need to do is unplug the drive from one adapter and plug it in to the other. I use SCSI drives extensively, and with SCSI I can get the same level of performance when the drive is connected to my laptop as when it is connected to a desktop system.

- *Internal enclosure.* Internal drives won't take up any space on your desk. Buy an internal drive if you have a free drive bay and a sufficient power supply and you plan to keep the drive exclusively on one machine. The internal drives are also nice because you can connect the audio connector to your sound card and leave the external audio connectors free for other inputs. Internal drives can be ATA or SCSI.

Adding a DVD Drive to Your System

A DVD drive installs in a manner similar to that of a CD-ROM or any other type of drive. See Chapter 14, "Physical Drive Installation and Configuration," to learn how to install a 5 1/4" DVD drive.

Following are some basic principles to keep in mind when installing a DVD drive:

- *Most DVD drives are ATAPI devices.* So, you have the issue of master/slave setups on the dual-connector 40-pin ATA cable. If you're replacing an old CD-ROM drive, simply note its master/slave configuration when you remove it from your system, set the new DVD drive the same way, attach it to the data cable, connect the power, and you're finished.
- *Many current DVD drives require that you connect them to a busmastering ATA interface.* If your drive requires a busmastering interface, check out the tips later in this chapter.
- *If you want to play DVD movies using your drive, you need an MPEG-2 decoder.* This can be either a card (hardware decoder) or a program (software decoder). If you are using a hardware decoder, it requires an open PCI expansion slot, as well as an interrupt request (IRQ) resource from your system. Also, to view the movies on your PC's display, you must somehow connect the decoder card to your existing video card. This can be accomplished via an internal connection to the card, or it can use a loop through connection to the monitor port on the back of the card. Some video cards include MPEG-2 decoders (players) built in. Table 13.23 compares MPEG decoder cards to video cards with built-in MPEG players.

Table 13.23 MPEG Decoder Cards Versus Video Cards with MPEG Players

Consideration	MPEG Decoder	MPEG Player
PCI slot usage	One for decoder; one for VGA	One slot only
Movie image quality	High	Varies
Playback speed	High	Varies
MPEG game compatibility	Yes	No

Note that as processors have become more powerful, many DVD drives now ship with MPEG-2 software decoders. These eliminate the need for an MPEG-2 decoder card, and if your processor is fast enough, it allows for adequate performance when playing DVD video discs. Most of the decoders recommend a minimum of a 400MHz processor—of course, even faster would be better. Although the software decoders can work well, in most cases if you really plan on using your PC to watch DVD movies, it is worth the extra cost to get a hardware MPEG-2 decoder card.

Another performance issue is related to data transfer. Most ATAPI DVD drives support Ultra-DMA transfers. To achieve maximum performance from these drives, be sure to enable DMA transfers in your BIOS setup and in the DVD driver installed in your operating system. Most installation programs automatically enable DMA support in the driver, but it's a good idea to check anyway. Enabling DMA dramatically reduces the load on your processor and greatly enhances system performance when playing or reading DVDs.

Note that if you enable DMA and the drive or system does not support it, you might encounter a system lockup or instability. In that case, you might need to restart in Safe mode to disable DMA.

Writable CDs

Although the CD originally was conceived as a read-only device, these days you easily can create your own data and audio CDs. By purchasing CD-R or CD-RW discs and drives, you can record (or burn) your own CDs. This enables you to store large amounts of data at a cost that is lower than most other removable, random-access mediums.

It might surprise newcomers to the world of PCs to see just how far recordable CD technology, performance, and pricing has come. Today you can buy recorders that operate at up to 40x speeds and cost under $100. You can even purchase Slimline CD drives for laptops. This is compared to the first CD-R recording system on the market in 1988, which cost more than $50,000 (back then, they used a $35,000 Yamaha audio recording drive along with thousands of dollars of additional error correction and other circuitry for CD-ROM use), operated at 1x speed only, and was part of a subsystem that was the size of a washing machine! The blank discs also cost about $100 each—a far cry from the 25 cents or less they cost today (if you purchase in bulk and are willing to supply your own jewel cases). With prices that high, the main purpose for CD recording was to produce prototype CDs that could then be replicated via the standard stamping process.

In 1991, Philips introduced the first 2x recorder (the CDD 521), which was about the size of a stereo receiver and cost about $12,000. Sony in 1992 and then JVC in 1993 followed with their 2x recorders, and the JVC was the first drive that had the half-height 5 1/4" form factor that most desktop system drives still use today. In 1995, Yamaha released the first 4x recorder (the CDR100), which sold for $5,000. A breakthrough in pricing came in late 1995 when Hewlett-Packard released a 2x recorder (the 4020i, which was actually made for them by Philips) for under $1,000. This proved to be exactly what the market was waiting for. With a surge in popularity after that, prices rapidly fell to below $500, and then down to $200 or less. In 1996, Ricoh introduced the first CD-RW drive.

Compared with either tape or other removable media, using a CD burner is a very cost-effective and easy method for transporting large files or making archival copies. Another benefit of the CD for archiving data is that CDs have a much longer shelf life than tapes or other removable media.

Two main types of recordable CD drives and discs are available, called CD-R (recordable) and CD-RW (rewritable). Because all CD-RW drives can also function as CD-R drives, and the prices of CD-R and RW drives are similar, virtually all drives sold today are CD-RW. Those drives can work with either CD-R or CD-RW discs. In addition, because the CD-RW discs are 1.5–4 times more expensive than CD-R discs, only half as fast (or less) as CD-R discs, and won't work in all CD audio or CD-ROM drives, people usually write to CD-R media in their CD-RW drives.

Note

Because of differences in reflectivity of the media, older CD and DVD drives can't read CD-RW media. Most newer CD or DVD-ROM drives conform to the MultiRead specification and as such can read CD-RWs. But many older drives are still out there that do not conform. As such, if you are recording something that many people or systems will need to read, CD-R is your best choice for overall compatibility.

CD-R media is a WORM (write once, read many) media, meaning that after you fill a CD-R with data, it is permanently stored and can't be erased. The write-once limitation makes this type of disc less than ideal for system backups or other purposes in which it would be preferable to reuse the same media over and over. However, because of the low cost of CD-R media, you might find that making permanent backups to essentially disposable CD-R discs is as economically feasible as tape or other media.

CD-RW discs can be reused up to 1,000 times, making them suitable for almost any type of data storage task. When first introduced, there were many CD-R-only drives; however, today most recordable CD drives are both CD-R and CD-RW in one. The following sections examine these two standards and how you can use them for your own data storage needs.

CD-R

Once recorded, CD-R discs can be played back or read in any standard CD-ROM drive. CD-R discs are useful for archival storage and creating master CDs, which can be duplicated for distribution within a company.

CD-Rs function using the same principle as standard CD-ROMs, by bouncing laser light off the disc and tracking the changes in reflectivity when pit/land and land/pit boundaries are encountered. The main difference is that instead of being stamped or embossed into plastic as on regular CDs, CD-Rs have images of pits burned onto a raised groove instead. Therefore, the pits are not really raised bumps like on a standard CD, but instead are rendered as dark (burned) areas on the groove that reflect less light. Because the overall reflectivity of pit and land areas remains the same as on a stamped disc, normal CD-ROM or CD audio drives can read CD-Rs exactly as if they were stamped discs.

Part of the recording process with CD-Rs starts before you even insert the disc into the drive. CD-R media is manufactured much like a standard CD—a stamper is used to mold a base of polycarbonate plastic. However, instead of stamping pits and lands, the stamper imprints a spiral groove (called a *pre-groove*), into the disc. From the perspective of the reading (and writing) laser underneath the disc, this groove is seen as a raised spiral ridge and not a depression.

The pre-groove (or ridge) is not perfectly straight; instead it has a slight wobble. The amplitude of the wobble is generally very small compared to the track pitch (spacing). The groove separation is 1.6 microns, but it wobbles only 0.030 microns from side to side. The wobble of a CD-R groove is modulated to carry supplemental information read by the drive. The signal contained in the wobble is called absolute time in pre-groove (ATIP) because it is modulated with time code and other data. The time code is the same minutes:seconds:frame format that will eventually be found in the Q-subcode of the frames after they are written to the disc. The ATIP enables the drive to locate positions on the disc before the frames are actually written. Technically, the wobble signal is frequency shift keyed with a carrier frequency of 22.05KHz and a deviation of 1KHz. The wobble uses changes in frequency to carry information.

To complete the CD-R disc, an organic dye is evenly applied across the disc by a spin-coating process. Next, a gold reflective layer is applied, followed by a protective coat of UV-cured lacquer to protect the gold and dye layers. Gold is used in CD-R discs to get the reflectivity as high as possible, and it was found that the organic dye tends to oxidize aluminum. Then, silk-screen printing is applied on top of the lacquer for identification and further protection. When seen from the underside, the laser used to read (or write) the disc first passes through the clear polycarbonate and the dye layer, hits the gold layer where it is reflected back through the dye layer and the plastic, and finally is picked up by the optical pickup sensor in the drive.

The dye and reflective layer together have the same reflective properties as a *virgin* CD. In other words, a CD reader would read the groove of an unrecorded CD-R disc as one long land. To record on a CD-R disc, a laser beam of the same wavelength (780nm) as is normally used to read the disc, but with 10 times the power, is used to heat up the dye. The laser is fired in a pulsed fashion at the top of the ridge (groove), heating the layer of organic dye to between 482°F and 572°F (250°–300°C). This temperature literally burns the organic dye, causing it to become opaque. When read, this prevents the light from passing through the dye layer to the gold and reflecting back, having the same effect of canceling the laser reflection that an actual raised pit would on a normal stamped CD.

Figure 13.11 shows the CD-R media layers, along with the pre-groove (raised ridge from the laser perspective) with burned pits.

The drive reading the disc is fooled into thinking a pit exists, but no actual pit exists—there's simply a spot of less-reflective material on the ridge. This use of heat to create the pits in the disc is why the recording process is often referred to as *burning* a CD. When burned, the dye changes from a reflective to a nonreflective state. This change of state is permanent and can't be undone, which is why CD-R is considered a write-once medium.

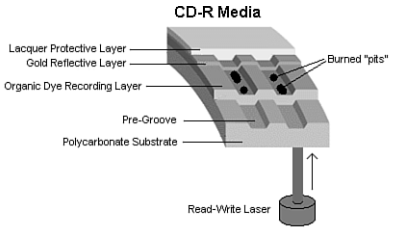

Figure 13.11 CD-R media layers.

CD-R Capacity

All CD-R drives can work with the standard 650MiB (682MB) CD-R media (equal to 74 minutes of recorded music), as well as the higher-capacity 700MiB (737MB) CD-R blanks(equal to 80 minutes of recorded music). The 80-minute discs cost only about 2 cents more than the 74-minute discs, so most would figure why not purchase only the higher-capacity media? Although the extra 55MB of storage can be useful and the cost difference is negligible, the 80-minute discs can actually be harder to read on older CD-ROM and CD-DA drives, especially car audio units. This is because to get the extra 55MB/6 minutes of capacity, the spiral track is wound a little more tightly, making them a bit more difficult read. If you'll be using the discs for audio or interchange purposes and might be dealing with older equipment, you might want to stick with the 74-minute discs instead. If not, the 80-minute media will be just fine.

Some drives and burning software are capable of overburning, whereby they write data partially into the lead-out area and essentially extend the data track. This is definitely risky as far as compatibility is concerned. Many drives, especially older ones, fail when reading near the end of an overburned disc. It's best to consider this form of overclocking CDs somewhat experimental. It might be useful for your own purposes if it works with your drives and software, but interchangeability will be problematic.

CD-R Media Color

There has been some controversy over the years about which colors of CD-R media provide the best performance. Table 13.24 shows the most common color combinations, along with which brands use them and some technical information.

Some brands are listed with more than one color combination, due to production changes or different product lines. You should check color combinations whenever you purchase a new batch of CD-R media if you've found that particular color combinations work better for you in your applications.

Table 13.24 CD-R Media Color and Its Effect on Recording

Media Color (first color is reflective layer; second is die layer)	Brands	Technical Notes
Gold-gold	Mitsui, Kodak, Maxell, Ricoh	Phthalocyanine dye Less tolerance for power variations; might be less likely to work in a wide variety of drives; invented by Mitsui Toatsu Chemicals; works best in drives that use a Long Write Strategy (longer laser pulse) to mark media
Gold-green	Imation (nee 3M), Memorex, Kodak, BASF, TDK	Cyanine dye; more forgiving of disc-write and disc-read variations; has a rated life span of 10 year color combination developed by Taiyo Yuden; used in the development of the original CD-R standards; de facto standard for CD-R industry and was the original color combination used during the development of CD-R technology; works best in drives that use a Short Write Strategy (shorter laser pulse) to mark media
Silver-blue	Verbatim, DataLifePlus, HiVal, Maxell, TDK	Process developed by Verbatim Azo dye; similar performance to green media plus rated to last up to 100 years; a good choice for long-term archiving

Note

Playstation games originally came on discs that were tinted black for appearance. Soon blank CD-R recordable discs were also available with this same black tint in the polycarbonate. The black tint is purely cosmetic—it is invisible to the infrared laser that reads/writes the disc. In other words, "black" CD-R discs are functionally identical to clear discs and can be made using any of the industry-standard dyes in the recording layer. The black tint hides the recording layer visually, so although the laser passes right through it, the black tint prevents you from observing the color of the dye in the recording layer directly.

Ultimately, although the various color combinations have their advantages, the best way to choose a media type is to try a major brand of media in your CD-R/CD-RW drive with both full-disc and small-disc recording jobs and then try the completed CD-R in as wide a range of CD-ROM drive brands and speeds as you can.

The perfect media for you will be the ones that offer you the following:

- High reliability in writing
- No dye or reflective surface dropouts (areas where the media won't record properly)
- Durability through normal handling (scratch-resistant coating on media surface)

- Compatibility across the widest range of CD-ROM drives
- Lowest unit cost

Choosing the Best Media

After you determine which media works best for you and your target drives, you might still be faced with a wide variety of choices, including conventional surface, printable surface, unbranded, jewel case, and bulk on spindle. The following list discusses these options:

- *Conventional surface.* Choose this type of media if you want to use a marker to label the CD rather than adding a paper label. This type of CD often has elaborate labeling, including areas to indicate CD title, date created, and other information as well as prominent brand identification. Because of the surface marking, it's not suitable for relabeling unless you use very opaque labels. It's a good choice for internal backups and data storage, though, where labeling is less important.
- *Printable surface.* Choose this type of media if you have a CD printer (a special type of inkjet printer that can print directly onto the face of the CD). Because the brand markings are usually low-contrast or even nonexistent (to allow overprinting), this type also works well with labeling kits such as NEATO and others.
- *Unbranded.* Usually sold in bulk on spindle, these are good choices for economy or use with labeling kits.
- *Jewel case.* Any of the preceding versions can be sold with jewel cases (the same type of case used for CD-ROM software and music CDs). This is a good choice if you plan to distribute the media in a jewel case, but it raises your costs if you plan to distribute or store the media in paper, Tyvek, or plastic sleeves. Hint: Use extra jewel cases to replace your broken jewel cases in your CD software or music collection!
- *Bulk on spindle.* This media generally comes with no sleeves and no cases. It is usually the lowest-priced packaging within any brand of media. This is an excellent choice for mass duplication, or for those who don't use jewel cases for distribution.

CD-R Media Recording Speed Ratings

With CD-R mastering speeds ranging from 1x (now-discontinued first-generation units) up through fast 12x and state-of-the-art 20x rates, it's important to check the speed rating (x-rating) of your CD-R media.

Most branded media on the market today is rated to work successfully at up to 16x recording speeds. Some brands indicate this specifically on their packaging, whereas you must check the Web sites for others to get this information.

If speed ratings are unavailable, you might want to restrict your burning to 8x or lower. Media that is 16x or higher rated is now the most popular, but speed ratings higher than that might be more difficult to find.

CD-RW

Beginning in early 1996, an industry consortium that included Ricoh, Philips, Sony, Yamaha, Hewlett-Packard, and Mitsubishi Chemical Corporation announced the CD-RW format. The design was largely led by Ricoh, and it was the first manufacturer to introduce a CD-RW drive in May 1996. This drive was the MP6200S, which was a 2/2/6 (2x record, 2x rewrite, 6x read) rated unit. At the same time, the Orange Book Part III was published, which officially defined the CD-RW standard.

Since that time, CD-RW drives have pretty much replaced CD-R-only drives in the market today, mainly because CD-RW drives are fully backward-compatible with CD-R drives and can read and write the same CD-R media with the same capabilities. So, a CD-RW drive can also function as a CD-R drive. CD-RW discs can be burned or written to just like CD-Rs; the main difference is that they can be erased and reburned again and again. They are very useful for prototyping a disc that will then be duplicated in less expensive CD-R or even stamped CDs for distribution. They can be rewritten at least 1,000 times or more. Additionally, with packet-writing software, they can even be treated like giant floppy disks, where you can simply drag and drop or copy and delete files at will. Although CD-RW discs are about twice as expensive as CD-R media, CD-RWs are still far cheaper than optical cartridges and other removable formats. This makes CD-RW a viable technology for system backups, file archiving, and virtually any other data storage task.

Note

The CD-RW format originally was referred to as CD-Erasable, or CD-E.

Four main differences exist between CD-RW and CD-R media. In a nutshell, CD-RW discs are

- Rewritable
- More expensive
- Slower when writing
- Less reflective

Besides the CD-RW media being rewritable and costing a bit more, they also are writable at about half (or less) the speed of CD-R discs. This is because the laser needs more time to operate on a particular spot on the disk when writing. They also have a lower reflectivity, which limits readability in older drives. Many older standard CD-ROM and CD-R drives can't read CD-RWs. However, MultiRead capability is now found in virtually all CD-ROM drives of 24x speed or above, enabling them to read CD-RWs without problems. In general, CD-DA drives—especially the car audio players—seem to have the most difficulty reading CD-RWs. So, for music recording or compatibility with older drives, you should probably stick to CD-R media. Look for the MultiRead logo on a CD-ROM drive, which indicates the capability to read CD-RW.

CD-RW drives and media use a phase change process to create the illusion of pits on the disc. As with CD-R media, the disc starts out with the same polycarbonate base with a wobbled pre-groove molded in, which contains ATIP information. Then, on top of the base a special dielectric (insulating) layer is spin-coated, followed by the phase change recording layer, another dielectric layer, an aluminum reflective layer, and finally a UV-cured lacquer protective layer (and optional screen printing). The dielectric layers above and below the recording layer are designed to insulate the polycarbonate and reflective layers from the intense heat used during the phase-change process.

Figure 13.12 shows the CD-RW media layers, along with the pre-groove (raised ridge from the laser perspective) with burned pits in the phase change layer.

Instead of burning an organic dye as with CD-R, the recording layer in a CD-RW disc is made up of a phase-change alloy consisting of silver, indium, antimony, and tellurium (Ag-In-Sb-Te). The reflective part of the recording layer is an aluminum alloy, the same as used in normal stamped discs. The read/write laser works from the underside of the disk, where the groove again appears like a ridge, and the recording is made in the phase-change layer on top of this ridge.

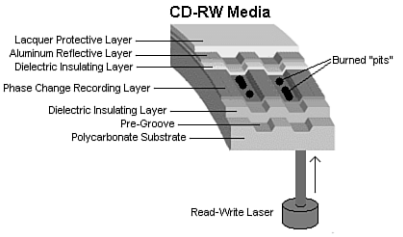

Figure 13.12 CD-RW media layers.

The recording layer of Ag-In-Sb-Te alloy normally has a polycrystalline structure that is about 20% reflective. When data is written to a CD-RW disc, the laser in the drive alternates between two power settings, called P-write and P-erase. The higher power setting (P-write) is used to heat the material in the recording layer to a temperature between 500°C and 700°C (932°–1,292°F), causing it to melt. In a liquid state the molecules of the material flow freely, losing their polycrystalline structure and taking what is called an *amorphous* (random) state. When the material then solidifies in this amorphous state, it is only about 5% reflective. When being read, these areas lower in reflectivity simulate the pits on a stamped CD-ROM disc.

That would be all to the story if CD-RW discs were read-only, but because they can be rewritten, there must be a way to bring the material back to a polycrystalline state. This is done by setting the laser to the lower-power P-erase mode. This heats the active material to approximately 200°C (392°F), which is well below the liquid melting point but high enough to soften the material. When the material is softened and allowed to cool more slowly, the molecules realign from a 5% reflective amorphous state back to a 20% reflective polycrystalline state. These higher reflective areas simulate the lands on a stamped CD-ROM disc.

Note that despite the name of the P-erase laser power setting, the disc is not ever explicitly "erased." Instead, CD-RW uses a recording technique called *direct overwrite*, in which a spot doesn't have to be erased to be rewritten; it is simply rewritten. In other words, when data is recorded the laser remains on and pulses between the P-write and P-erase power levels to create amorphous and polycrystalline areas of low and high reflectivity, regardless of which state the areas were in prior. It is similar in many ways to writing data on a magnetic disk that also uses direct overwrite. Every sector already has data patterns, so when you write data, all you are really doing is writing new patterns. Sectors are never really erased; they are merely overwritten. The media in CD-RW discs is designed to be written and rewritten up to 1,000 times.

CD-RW Speeds

The original Orange Book Part III Volume 1 (CD-RW specification) allowed for CD-RW writing at up to 4x speeds. New developments in the media and drives were required to support speeds higher than that. So in May 2000, Part III Volume 2 was published, defining CD-RW recording at speeds from 4x to 10x. This new revision of the CD-RW standard is called High-Speed Rewritable, and both the discs and drives capable of CD-RW speeds higher than 4x will indicate this via the logos printed on them.

Because of the differences required in the High-Speed media (discs), they can be used only in High-Speed CD-RW drives. If you try to write on the High-Speed media in a 2x or 4x CD-RW drive, the recording will fail and you will possibly see several error messages. Note that you can use the slower 4x or less rated media in the High-Speed drives, providing you write at only the 4x or lower speed for which the media is rated.

Mount Rainier

Mount Rainier is a new standard being promoted by Philips, Sony, Microsoft, and Compaq. Also called EasyWrite, it enables native operating system support for data storage on CD-RW and DVD+RW. This makes the technology much easier to use (no special drivers or packet-writing software is necessary) and enables CD-RW and DVD+RW drives to become a fully integrated storage solution. The main features of Mount Rainier are

- Integral defect management
- Direct addressing at the 2KB sector level
- Background formatting
- Standardized command set
- Standardized physical layout

To use Mount Rainier, you must have a drive that supports the standard. These are called CD-MRW or DVD+MRW drives, and they also might bear either the Mount Rainier or EasyWrite logo. Some existing CD-RW drives can be updated to MRW status by reflashing the firmware in the drive; however, most older drives will need to be replaced instead. Also required is software support directly in the operating system (such as with Windows XP or later), or software support can be added via a third-party add-on application for older operating systems.

The first Mount Rainier drive (Philips RWDV1610B) was released in April 2002, and since then many more have followed. Because only minor changes are required in the drive circuitry and firmware to enable Mount Rainier support, virtually all newer drives include Mount Rainier capability. In addition, the DVD+RW standard was designed with Mount Rainier compatibility in mind—defect management was included inherently from the beginning. DVD+RW drives with Mount Rainier capability are sometimes called DVD+MRW drives.

Because Mount Rainier essentially makes CD-MRW and DVD+MRW drives function as high-capacity replacements for floppy, Zip, and SuperDisk drives, it won't be long before those are but a distant memory.

Blu-ray Disc

In February 2002, nine of the leading optical storage companies announced the initial specifications for Blu-ray Disc, a high-capacity CD/DVD-type optical disc format. Blu-ray is a fully rewritable format that enables recording up to 27GB of data or up to 2 hours of high-definition video on a single-sided, single-layer 12cm disc (which is the same as existing CDs and DVDs) using a 405nm blue-violet laser. Blu-ray discs will be contained in a cartridge that protects them from dust and fingerprints.

Licensing for the technology is expected to start around spring 2002, and commercial products should arrive a year or so after that.

The companies who created and license the Blu-ray Disc specification include

- Hitachi, Ltd.
- LG Electronics, Inc.
- Matsushita Electric Industrial Co., Ltd.
- Pioneer Corporation
- Royal Philips Electronics

- Samsung Electronics Co., Ltd.
- Sharp Corporation
- Sony Corporation
- Thomson Multimedia

One of the main applications for higher-capacity optical storage is recording high-definition TV, which takes an incredible amount of storage. Current DVD recorders can't store enough data to handle high-definition video. Blu-ray, on the other hand, is designed to store up to 2 hours of high-definition video (or more than 13 hours of standard broadcast-quality TV) on a single disc. As with DVD, Blu-ray uses the industry-standard MPEG-2 compression technology.

Standard CDs use a 780nm (infrared) laser combined with a 0.45 numerical aperture lens, whereas DVDs use a 650nm (red) laser combined with a 0.60 numerical aperture lens. Blu-ray uses a much shorter 405nm (blue-violet) laser with a 0.85 numerical aperture lens. *Numerical aperture* is a measurement of the light gathering capability of a lens, as well as the focal length and relative magnification. The numerical aperture of a lens is derived by taking the sine of the maximum angle of light entering the lens. For example, the lens in a CD-ROM drive gathers light at up to a 26.7° angle, which results in a numerical aperture of SIN(26.7) = 0.45. By comparison, the lens in a DVD drive gathers light at up to a 36.9° angle, resulting in a numerical aperture of SIN(36.9) = 0.60. Blu-ray drives gather light at up to a 58.2° angle, resulting in a numerical aperture of SIN(58.2) = 0.85. Higher numerical apertures allow increasingly oblique (angled) rays of light to enter the lens and therefore produce a more highly resolved image.

The higher the aperture, the shorter the focal length and the greater the magnification. The lens in a CD-ROM drive magnifies roughly 20 times, whereas the lens in a DVD drive magnifies about 40 times. The Blu-ray lens magnifies about 60 times. This greater magnification is necessary because the distance between tracks on a Blu-ray disc is reduced to 0.32um, which is almost half of that of a regular DVD. Because of the very high densities involved, a simple cartridge is used to hold the disc, which prevents it from being impaired by dust, fingerprints, or scratches.

The most important features of a Blu-ray disc are summarized in Table 13.25.

Table 13.25 Blu-ray Disc Specifications

Specification	Value
Recording capacity	23.3GB/25GB/27GB
Laser wavelength	405nm (blue-violet)
Lens numerical aperture	0.85
Cartridge dimensions	Approximately 129×131×7mm
Disc diameter	120mm
Disc thickness	1.2mm
Optical protection layer	0.1mm
Tracking pitch	0.32um
Shortest pit length	0.160/0.149/0.138um
Recording density	16.8/18.0/19.5Gb/sq. in.
Data transfer rate	36Mbps
Recording format	Phase change recording
Tracking format	Groove recording
Video format	MPEG2

Blu-ray or perhaps some other blue-laser disc drive will eventually become the replacement for today's DVD drives.

MultiRead Specifications

The original Red and Yellow Book CD standards specified that on a CD the lands should have a minimum reflectance value of about 70% and the pits should have a maximum reflectance of about 28%. Therefore, the area of a disc that represents a land should reflect back no less than 70% of the laser light directed at it, whereas the pits should reflect no more than 28%. In the early 1980s when these standards were developed, the photodetector diodes used in the drives were relatively insensitive, and these minimum and maximum reflectance requirements were deliberately designed to create enough brightness and contrast between pits and lands to accommodate them.

On a CD-RW disc, the reflectance of a land is approximately 20% (plus or minus 5%) and the reflectivity of a pit is only 5%—obviously well below the original requirements. Fortunately, it was found that by the addition of a relatively simple AGC circuit, the ratio of amplification in the detector circuitry can be changed dynamically to allow for reading the lower-reflective CD-RW discs. Thus, although CD-ROM drives were not initially capable of reading CD-RW discs, modifying the existing designs to enable them to do so wasn't difficult. Where you might encounter problems reading CD-RW discs is with CD audio drives, especially older ones. Because CD-RW first came out in 1996 (and took a year or more to become popular), most CD-ROM drives manufactured in 1997 or earlier have problems reading CD-RW discs. Reflectivity is also a problem on DVD-Video and DVD-ROM drives—because they use a different frequency laser, they actually have more trouble reading CD-R discs than CD-RWs.

DVDs also have some compatibility problems. With DVD, the problem isn't just simple reflectivity as it is an inherent incompatibility with the laser wavelength used for DVD versus CD-R and RW. The problem in this case stems from the dyes used in the recording layer of CD-R and RW discs, which are very sensitive to the wavelength of light used to read them. At the proper CD laser wavelength of 780nm, they are very reflective, but at other wavelengths, the reflectivity falls off markedly. Normally, CD-ROM drives use a 780nm (infrared) laser to read the data, whereas DVD drives use a shorter wavelength 650nm (red) laser. Although the shorter wavelength laser works well for reading commercial CD-ROM discs because the aluminum reflective layer they use is equally reflective at the shorter DVD laser wavelength, it doesn't work well at all for reading CD-R or RW discs.

Fortunately, a solution was first introduced by Sony and then similarly by all the other DVD drive manufacturers. This solution consists of a dual-laser pickup that incorporates both a 650nm (DVD) and 780nm (CD) laser. Some of these used two discrete pickup units with separate optics mounted to the same assembly, but they eventually changed to dual-laser units that use the same optics for both, making the pickup smaller and less expensive. Because most manufacturers wanted to make a variety of drives—including cheaper ones without the dual-laser pickup—a standard needed to be created so that someone purchasing a drive would know the drive's capabilities.

So, how can you tell whether your drive is compatible with CD-R and RW discs? To demonstrate the compatibility of a particular drive, OSTA created industry standard tests and logos that would guarantee specific levels of compatibility. These are called the MultiRead specifications. Currently there are two levels, as follows:

- *MultiRead*. For CD-ROM drives
- *MultiRead2*. For DVD-ROM drives

In addition, a similar MultiPlay standard exists that is for consumer DVD-Video and CD-DA devices.

Table 13.26 shows the two levels of MultiRead capability that can be assigned to drives and the types of media guaranteed to be readable in such drives.

Table 13.26 MultiRead and MultiRead2 Compatibility Standards for CD/DVD Drives

Media	MultiRead	MultiRead2
CD-DA	X	X
CD-ROM	X	X
CD-R	X	X
CD-RW	X	X
DVD-ROM	—	X
DVD-Video	—	X
DVD-Audio	—	X
DVD-RAM	—	X

X = Compatible; drive will read this media

— = Incompatible; drive won't read

Note that MultiRead also indicates that the drive is capable of reading discs written in Packet Writing mode because this mode is now being used more commonly with both CD-R and RW media.

To determine whether your drive meets either of these standards, merely look for the MultiRead or MultiRead2 logo on the drive, as shown in Figure 13.13.

Figure 13.13 MultiRead and MultiRead2 logos.

The presence of these logos guarantees that particular level of compatibility. If you are purchasing a CD-ROM or DVD drive and want to be able to read recordable or rewritable discs, be sure to look for the MultiRead or MultiRead2 logo on your drive. Especially in the case of DVD drives, MultiRead2 versions are generally more expensive because of the extra cost of the dual-mode laser pickup required. Virtually all DVD-ROM drives for computers have the dual pickup mechanism, enabling them to properly read CD-R or CD-RW discs. However, most DVD video players used in entertainment systems do not have the dual pickups.

How to Reliably Record CDs

With typical burn times for full CD-Rs ranging from under 4 minutes (20x) to as long as 80 minutes (1x), it is frustrating when a buffer underrun or some other problem forces you to rewrite your CD-RW disc, or worse yet, turn your CD-R media to a coaster—an unusable disc that must be discarded.

Five major factors influence your ability to create a working CD-R: interface type, drive buffer size, the location and condition of the data you want to record to CD-R, the recording speed, and whether the computer is performing other tasks while trying to create the CD-R.

To improve the odds of getting reliable CD-R/RW creation, look for drives with

- *A large data buffer (2MB or larger), or better yet some form of buffer underrun protection.* The data buffer in the drive holds information read from the original data source, so that if a pause in data reading occurs, there's less of a possibility of a buffer underrun until the on-drive buffer runs empty. A larger buffer minimizes the chance of "running out of data." Newer drives with buffer underrun protection virtually eliminate this problem, no matter what size buffer is in the drive.
- *Support for UDMA operating modes.* As you've already seen, UDMA modes transfer data more quickly and with less CPU intervention than earlier versions of ATA. To use this feature, you'll also need a motherboard with a busmastering UDMA interface with the appropriate drivers installed.

Tip

Also, if you have problems with reliable CD-R creation at the drive's maximum speed, try using a lower speed (4x instead of 8x, for example). Your mastering job will take twice as long, but it's better to create a working CD-R slowly than ruin a blank quickly.

An alternative approach is to use packet-writing software to create your CD-R. All late-model CD-R/CD-RW drives support packet writing, which allows drag-and-drop copying of individual files to the CD-R/RW rather than transferring all the files at once as with normal mastering software. This "a little at a time" approach means that less data must be handled in each write and can make the difference between success and failure. If your drive supports this feature, it probably includes packet-writing software in the package. Note that although packet-written CDs can be read with Windows 9x, Me, NT, and 2000, they can't be read with Windows 3.1 and MS-DOS because these operating systems don't have drivers available that support packet-written CDs.

If your CD-R/RW drive is SCSI based, be sure you have the correct type of SCSI interface card and cables. Although many drive vendors take the uncertainty out of this issue by supplying an appropriate card and cables, others don't.

If you must buy your own SCSI card for your recorder, follow these tips:

- *Forget about ISA cards.* Many new motherboards no longer include ISA slots, and even if they do, the performance of the ISA bus presents a bottleneck that will seriously inhibit drive performance.
- *PCI or Cardbus SCSI works well.* As discussed in Chapter 17, "I/O Interfaces from Serial and Parallel to IEEE-1394 and USB," PCI's 32-bit data bus and 33MHz typical performance is far faster than ISA's 16-bit data bus and 8.33MHz typical performance. Cardbus is PCI for notebooks, so the same benefits apply there as well.

Tip

Several CD-R manufacturers, including Adaptec, Amedia, Promise Tech, SIIG, Tekram, DTC, and Advansys, offer high-performance PCI SCSI cards.

Buffer Underruns

Whenever a drive writes data to a CD-R/RW disc in either Disk at Once or Track at Once mode, it writes to the spiral track on the CD, alternating on and off to etch the pattern into the raw media. Because the drive can't easily realign where it starts and stops writing like a hard drive can, after it starts writing it must typically continue until it's finished with the track or disc. Otherwise, the

recording (and disc if it is a CD-R) will be ruined. This means that the CD recording software, in combination with your system hardware, must be capable of delivering a consistent stream of data to the drive while it's writing. To aid in this effort, the software uses a buffer that it creates on your hard disk to temporarily store the data as it is being sent to the drive.

If the system is incapable of delivering data at a rate sufficient to keep the drive happy, you receive a buffer underrun message and the recording attempt fails. The buffer underrun message indicates that the drive had to abort recording because it ran out of data in its buffer to write to the CD. For many years, this was the biggest problem people had when recording to CD-R/RW media. And for many years, the best way to prevent buffer underruns was to either slow down the writing speeds or have a large buffer in the recording drive, as well as to use the fastest interface and reading drive as possible. Nobody wants to write at lower speeds (otherwise, why buy a fast drive?), so buffer sizes grew as did the interface speeds. Still, it was possible to get a buffer underrun if, for example, you tried browsing Web pages or doing other work while burning a disc.

Buffer Underrun Protection

Sanyo was the first to develop a technology that eliminates buffer underruns once and for all. It calls the technology BURN-Proof ("BURN" stands for "buffer underrun"), which sounds a little confusing (some people thought it prevented any writing on discs), but in practice it has proven to be excellent.

After Sanyo, several other companies have developed similar and compatible technology with various names. Including Sanyo's, the most common you'll see are:

- BURN-Proof, from Sanyo
- JustLink, from Ricoh
- Waste-Proof, from Yamaha

Buffer underrun protection technology involves having a special chipset in the drive that monitors the drive buffer. When it anticipates that a buffer underrun might occur (the buffer is running low on data), it temporarily suspends the recording until more data fills the buffer. When the buffer is sufficiently restocked, the drive then locates exactly where the recording left off earlier and restarts recording again immediately after that position.

According to the Orange Book specification, gaps between data in a CD recording must not be more than 100 milliseconds in length. The buffer underrun technology can restart the recording with a gap of 40–45 milliseconds or less from where it left off, which is well within the specification. These small gaps are easily compensated for by the error correction built into the recording, so no data is lost.

Note that it is important that the drive incorporate buffer underrun technology, but the recording software must support it as well for everything to work properly. Fortunately, all the popular CD recording programs on the market now support this technology.

If your drive incorporates buffer underrun protection, you can multitask—do other things while burning CDs—without fear of producing a bad recording.

Producing Error-Free Recordings

If you have an older drive that doesn't feature buffer underrun protection, follow these recommendations to help ensure error-free recordings and prevent buffer underruns:

- *Whenever possible, move all the data you want to put onto a CD-R to a fast local hard drive.* If you can't do this, avoid using the following sources for data: floppy drives, parallel port–connected storage drives, and slower CD-ROM drives (especially 8x or slower). These locations for data usually can't feed data quickly enough to maintain data flow to the recording drive.

- *Before you master the CD-R, check your hard disk or data source for errors (the scandisk program can often be used for this).* Also try defragmenting the drive. This ensures that disk errors or file fragmentation, both of which slow down disk access, won't be a factor in program or data search and retrieval.
- *Avoid trying to burn from active files or zero-byte files (often used for temporary storage).* If you must burn these files to make an archival copy of your current system configuration, use a program such as Norton Ghost or PowerQuest Drive Image. These programs create a single compressed file from your drive's contents. Then, burn the disc using the resulting compressed file.
- *Turn off power management for your hard disk and other peripherals.* In Windows you normally do this through the Power icon in the Control Panel.
- *Make sure your temporary drive has at least twice the empty space of your finished CD.* Your CD's estimated space requirements are shown during the mastering process with programs such as Roxio Easy CD-Creator or NERO Burning ROM. Thus, if you're creating a CD with 500MB of data, your temporary drive should have at least 1GB of empty space.
- *With Windows 9x, you'll improve disk caching by adjusting the typical role of the computer from workstation to server in the Performance tab of the System Properties dialog box.* Note that this change works correctly with Windows 95B and 95C (OSR 2.x) and Windows 98/Me, but the Registry keys are incorrect in Windows 95 original retail and OSR1 (95A) versions. Check Microsoft's Web site for the correct Registry key settings for Windows 95/95A, back up and edit the Registry, and restart the computer before making this change with those versions.
- *If your original data is coming from a variety of sources, consider using the Create Disk Image option found in most CD mastering software.* This feature creates an image file on your hard drive that contains all the files you want to put onto a CD. Then, use Create CD from Disk Image to actually master the CD from that information.
- *If you're uncertain of success, why waste a CD-R blank?* Use a CD-RW instead, which usually is written at a slower speed, or use the "test-then-create" option found in most recording software that does a simulated burn of the CD before the actual creation. After the simulation, you're warned of any problems before the actual process begins. This is not always foolproof, but it can help.
- *Small files are harder to use in mastering a CD than large ones because of the excessive drive tracking necessary to find them and load them.* You might want to use the Packet Writing mode instead if your drive and software support it.
- *Keep your drives clean and free from dust.* Use a cleaning CD if necessary. Dirty drives cause data-read errors or data-write errors if your recording drive is the dirty one.
- *Don't multitask.* If you run another program during the mastering process, the computer is forced to perform time-slicing, which causes it to start a process, switch away from it to start the next process, switch back to the first process, and so forth. This switching process could cause the recording drive to run out of data because it isn't receiving data in a steady stream. Forget about surfing the Internet, playing Solitaire, or creating a label for your new CD during the burning process if you want reliable mastering on a drive that doesn't feature buffer underrun protection.

If you're still having buffer underrun problems despite taking all the precautions listed here, try dropping down a speed. Go to the next lower speed and see how you do. Using a lower speed than the drive is rated for can be frustrating, but it's preferable to wasting time creating unusable discs.

As a final note, I have also seen problems with burning CDs caused by inadequate power supplies. An inadequate or over-taxed power supply can cause myriad recording problems (including buffer underruns). I've seen cases in which the system seemed to be normal in most respects, but there were

tremendous problems recording CDs, from buffer underruns to power calibration errors. After upgrading the power supply with a high-quality, high-output unit, the problems all but disappeared. I've said it many times, but the power supply is the foundation of a PC, and in general it is the most failure-prone or problematic piece of hardware in the system. See Chapter 21, "Power Supply and Chassis/Case," for more information on power supplies, including recommended suppliers for upgraded units.

Recording Software

Another difficulty with CD-R/RW devices is that they usually require special software to write them. Although most cartridge drives and other removable media mount as standard devices in the system and can be accessed exactly like a hard drive, the CD-R/RW drive uses special CD-ROM burning software to write to the disc. This software handles the differences between how data is stored on a CD and how it is stored on a hard drive. As you learned earlier, there are several CD-ROM standards for storing information. The CD-ROM-burning software arranges the data into one of these formats so a CD-ROM reader can read the CD later. Windows XP and later include CD writing software built in; operating systems prior to that required that you purchase and install third-party CD writing software. Still, most have found that the popular third-party CD writing applications such as CD-Creator (Roxio) or Nero Burning ROM (Ahead Software) are far more powerful and easier to use.

At one time, CD recording technology required that you have what amounted to a replica of the CD on a local hard drive. In fact, some software packages even required a separate, dedicated disk partition for this purpose. You would copy all the files to the appropriate place on the hard drive, creating the directory structure for the CD, and then the software would create an exact replica of every sector for the proposed CD-ROM—including every file, all the directory information, and the volume information—and copy it to the CD-R drive. The result was that you had to have about 1.5GB of storage to burn a single CD (650MB/CD×2 = 1.3GB + overhead = 1.5GB). This is no longer a requirement because most software supports virtual images. You select the files and directories you want to write to the CD from your hard drive and create a virtual directory structure for the CD-ROM in the software. This means you can select files from different directories on different hard drives, or even files from network or other CD-ROM drives, and combine them any way you want on the CD-R. This works well provided the drives have adequate speed and your drive has a large buffer or features buffer underrun protection. If you have problems, follow the advice given earlier to overcome slow data sources.

The software assembles the directory information, burns it onto the CD, opens each file on the CD, and copies the data directly from the original source. This generally works well, but you must be aware of the access times for the media you select as data sources. If, for example, you select directories from a slow hard drive or from a busy network, the software might not be capable of reading the data quickly enough to maintain a consistent stream to the recorder. In drives lacking buffer underrun protection, this causes the write to fail, resulting in a wasted disc.

Don't Forget the Software!

If you have persistent problems with making CDs, your recording software or drive might be to blame. Check the vendor's Web site for tips and software updates. Some drives offer software-upgradable firmware similar to the motherboard's flash BIOS; if so, be sure your drive has the latest firmware available. Also make sure that your recording software is up-to-date and compatible with your drive and your drive's firmware revision.

Each of the major CD-R/CD-RW drive vendors provides extensive technical notes to help you achieve reliable recordings. You can also find helpful information on SCSI adapter vendors' Web sites and the Web sites of the media vendors.

Creating Music CDs

Newer CD-R, CD-RW, and CD-ROM drives are enabling people to create customized archives of their favorite prerecorded music. Roxio's Easy CD-Creator, for example, features the SoundStream utility to build music CDs and even removes pops, hiss, and other problems from old analog cassette tapes and vinyl LPs.

Digital audio extraction allows the digital tracks on commercial CDs to be transformed into WAV files by compatible mastering programs. Those WAV files, exactly like the ones created from older music sources via your sound card, can then create a CD-R, which can be played back in any popular CD stereo system.

Many users can take advantage of this type of software to burn greatest hits collections and holiday CDs from their purchased cassette and music CD collections.

This exciting technology is not intended to give you a way to create a free music library. Instead, use it to give the music recordings you've paid for an extra dimension of usefulness, and of course, to make legal backups of the discs you have purchased.

Digital Audio Extraction

All CD-ROM drives can *play* Red Book–formatted CD-DA discs, but not all CD-ROM drives can *read* CD-DA discs. The difference sounds subtle, but it is actually quite dramatic. If you enjoy music and want to use your PC to manage your music collection, the ability to read the audio data digitally is an important function for your CD (and DVD) drives because it enables you to much more easily and accurately store, manipulate, and eventually write back out audio tracks.

CD-ROM drives installed in PCs can play audio discs. The playing function is simple: Using a CD player application (such as the one included with Windows 95 and later), you can insert a CD-DA disc into a CD-ROM drive and play it just as you could with a standard audio CD player. While playing, the analog sound waveform is sent over a thin stereo cable (usually referred to as the CD audio cable) connected between your CD-ROM drive and the sound card in your PC. The same analog waveform usually is also sent to the headphone jack on the front of the drive (or sound card). Your sound card then amplifies the analog signal so you can hear it through the speakers plugged into your sound card or via headphones plugged into the front of the drive (or the sound card).

That is just fine if all you want to do is play discs, but if you ever want to record one of the songs on your hard disk, you will run into some problems. To transfer the song to your hard drive, you would have to play the song as you did normally and simultaneously use a sound recorder application, such as the Sound Recorder supplied with Windows 95 and later (similar recording software is also typically supplied with your sound card), to redigitize the audio waveform for storage as a .WAV file on the PC. This means the sound goes from digital as originally stored on the disc to analog in the CD-ROM drive and back to digital in your sound card, with the resulting digital file being only an approximation of the original digital data. Another drawback is that this procedure runs only at 1x speed—hardly an ideal situation!

It would be much better if you could read the original digital data directly off the disc. That was not possible with older CD-ROM drives, but newer drives can do what is called *digital audio extraction (DAE)*. In this process they read the digital audio sectors directly and, rather than decode them into analog signals, pass each 2,352-byte sector of raw (error-corrected) digital audio data directly to the PC's processor via the (ATA, SCSI, USB, or FireWire) drive interface cable. Therefore, no digital-to-analog conversion (and back) occurs, and you essentially get the audio data exactly as it was originally recorded on the CD (within the limits of the CD-DA error-correction standards). You would have essentially extracted the exact digital audio data from the disc onto your PC.

Another term for digital audio extraction is *ripping*, so named because you can "rip" the raw audio data from the drive at full drive read speed, rather than the normal 1x speed at which you listen to audio discs. Actually, most drives can't perform DAE at their full rated speeds. Although some are faster (or slower) than others, most perform DAE at speeds from about one-quarter to about one-half of their rated read speed. So, you might be able to extract audio data at speeds only up to 20x on a 40x rated drive. However, that is still quite a bit better than at 1x as it would be on drives that can't do DAE (not to mention skipping the conversion to analog and back to digital with the resultant loss of information).

Virtually all newer CD/DVD drives can perform digital audio extraction on music discs. How fast or accurately they do this varies from model to model. One might think any extraction (digital copy) of a given track (song) should be the same because it is a digital copy of the original; however, that is not always the case. The CD-DA format was designed to play music, not to transfer data with 100% accuracy. Errors beyond the capability of the CIRC in the CD-DA format cause the firmware in the drive to interpolate or approximate the data. In addition, time-based problems due to clock inaccuracies can occur in the drive, causing it to get slightly out of step when reading the frames in the sector (this is referred to as *jitter*). Differences in the internal software (firmware) in the drive and differences in the drivers used are other problems that can occur.

Positioning can also be a problem because the CD-DA format was designed to stream (play continuously) and not to read individual sectors. CD-ROM sectors are 2,352 bytes long, and these bytes are further divided into 2,048 bytes of data plus 304 bytes of synchronization, header, and additional ECC information to control positioning and allow for error-free reads. No such synchronization, header, or extra ECC information exists for audio sectors; instead, all 2,352 bytes are used for pure audio data. To address an audio sector, the Q subcode information is used instead (see the section "Subcodes," earlier in this chapter). Most audio players position to within only 75 sectors (1 second) using the Q subcode information. CD-ROM drives that can perform digital audio extraction are usually much more accurate than that, but because of how the subcode works (as well as the cross-interleaved way audio data is stored), designing a drive that can position every time to the precise audio sector that starts the track can be difficult.

All of this conspires to cause inaccuracies or slight differences in multiple extractions of the same track (song). Perfect extractions are possible, but making perfect extractions is difficult to achieve for many reasons. For example, even a slight amount of dirt or scratches on the disc has a great effect on the quality of your extractions, so be sure the discs are clean. As a test of your drive's capability to perform DAE, try extracting the same track (song) multiple times from a new, clean, scratch-free disc, using a different filename for each extraction. Then, bring up a command prompt and use the `FC` (file compare) command to compare the different files to each other. If they compare exactly, you have a combination of hardware and software that can do perfect or near-perfect extractions.

If you intend to do a lot of extracting, you should ask around to see what hardware and software others are using for this purpose. As a general rule, SCSI drives work better than ATA, but some ATA drives are just as good as the better SCSI drives. Plextor is well known for drives that are excellent when it comes to digital audio extraction, and I've always had good luck with Toshiba drives.

The bottom line is that DAE enables you to extract audio data tracks directly to your PC as .WAV files. Once on the PC, you can play the WAV files as is or convert them to other (usually more compressed) formats, such as MP3 (MPEG-1/2 Layer III) for use with the MP3 audio players on the market.

Note

Because the WAV files extracted match the high 44.1KHz sampling rate used on the CD, you have 176,400 bytes per second of sound information, which means 1 minute of music consumes nearly 10.6MB worth of space on your hard drive! MP3 compression can reduce that by a factor of 6 or more, with little to no perceptible loss in quality.

You can also use a CD-R/RW drive that can perform DAE to make copies of audio CDs (for backup purposes only) or to compile several songs into your own greatest hits collections that you can use to burn your own custom audio CDs.

Serial Copy Management System

Because of the possibility of the illegal duplication of commercial audio CDs, the recording industry is not in favor of DAE, and some drive manufacturers don't like to tout how well (or not so well) their drives perform this function.

The Recording Industry Association of America (RIAA) and others involved in the creation and distribution of prerecorded music were concerned about digital recording because no loss occurs in digital copies—a digital copy is just as good as the original. This also means that copies of copies are just as good, too. They feared that unless digital copying were somehow limited, it would easily allow the pirating of master-quality recordings.

The first digital recording technology accessible to consumers (before CD-R and CD-RW) was digital audio tape (DAT), which debuted to consumers in 1987. Because the DAT drive manufacturers could not reach an agreement with the RIAA on how to control copying, most record labels did not release any prerecorded software on DAT tapes. What followed instead was several years of controversy over digital copying, which finally culminated in an agreement in July 1989 mandating the inclusion of Serial Copy Management System (SCMS) in digital recorders, both tape and optical.

SCMS originally was developed by Philips and is designed to allow digital copies only from original source material. SCMS recognizes a "copyright" bit encoded on a prerecorded digital original (such as a CD, where it is contained in the Q subcode channel) indicating that this is an original and writes a modified bit signifying that this is now a copy into the subcode of digital copies (such as when copying to a CD-R/RW (or DAT tape). The presence of the copy flag prevents any SCMS-compliant recorder from digitally copying the copy. SCMS lets you digitally copy originals as many times as you want, but you can't digitally copy any of the copies. SCMS is included in all consumer "home audio" non-computer-based CD recorders, but not the CD-RW drives in your PC.

Audio Home Recording Act

What started as an agreement between the recording industry and drive manufacturers in 1989 was translated into law in the U.S. with the passage of the Audio Home Recording Act of 1992. The AHRA was passed by Congress to protect artists and recording companies from losing royalties from unauthorized copying of compact discs, but it was also passed to guarantee the consumers' right to engage in home audio recording, eliminating the fear of copyright suits when making copies for private, noncommercial, personal use.

The AHRA calls for the mandatory inclusion of serial copying technology in devices and media but applies only to devices or media designed or marketed for the "primary purpose" of making digital audio recordings. Therefore, standalone home audio CD writers (and the media they use) must include SCMS, but general-purpose computer devices such as CD-R/RW drives and media don't. Additionally, the AHRA has also been found to exclude MP3 players, much to the dismay of the RIAA. Sensing that the AHRA did not provide as much legal protection as the recording industry desired, a new group called the Secure Digital Music Initiative (SDMI) has been formed to develop voluntary, open standards for digital music.

"For Music Use Only" CD-R/RW discs

According to the Audio Home Recording Act, consumer CD recordable drives *and media* sold specifically for recording music are required to have specific safeguards against copying discs, mainly SCMS. That means these recorders can make digital copies only from original prerecorded discs. You can

copy a copy, but in that case, the data being recorded goes from digital to analog and back to digital on the second copy, resulting in a generational loss of quality.

The media for these recorders must be special as well. They work only with special discs labeled "For Music Use" or "For Consumer." These carry the standard Compact Disk Digital Audio Recordable logo that most are familiar with, but below that, as part of the logo, is an added line that says "For Consumer." These discs feature a special track prerecorded onto the disc, which the consumer music recorders look for. Built into the price of the AHRA-compliant media is a royalty for the music industry that this track protects. The media costs about six times what regular CD-R/RW media costs. If you try to use standard non-AHRA-compliant CD-R/RW discs in these drives, the drive refuses to recognize the disc. These music devices also refuse to copy CD-ROM or data discs.

Note that this does not apply to the CD-R/RW drive you have installed or attached to your PC. It does not have to be AHRA compliant, nor does it need to use AHRA-compliant "For Music Use" media, even if you are copying or recording music discs. Additionally, you can make digital copies of copies—the SCMS does not apply, either. The bottom line is that you do not have to purchase AHRA-compliant discs for the CD-R/RW drives in your PC. If you do purchase such discs, despite the "For Music Use Only" designation, AHRA-compliant discs can be used in your CD-R/RW drives just as regular CD-R/RW discs and can be used for storing data. The extra information indicating AHRA compliance is simply ignored.

CD Copy Protection

At the time CDs debuted in late 1982, there was no worry from the industry about copying because CDs were read only and could be produced only by large-scale stamping equipment. Even more than 10 years later, CD recorders had become available but were extremely difficult to use and cost upwards of $10,000. Even the blanks were about $35 each, often costing more than the originals you wanted to back up.

Now that more than 20 years has elapsed, things have changed considerably and recording CDs is both easy and inexpensive. Unfortunately for the recording industry, the cat was already out of the bag so to speak, and adding copy protection late in the game has proven to be problematic. It is because of this that DVDs were designed with integral copy protection from the start, which the entertainment industry had insisted on before it would allow material to be released in that format. Fortunately, though, every single type of copy protection system for CDs and DVDs has been broken, allowing users to exercise their right to make backups.

Worries about the public copying of software and music CDs has prompted the development of copy protection techniques that attempt to make these discs uncopyable. There are different methods of protecting software CDs versus music CDs, but the end result is the same: You are prevented from making normal copies, or the copies don't work properly. In the case of music CDs, the copy protection can be quite obtrusive, adding noise to the recording, and in extreme cases preventing the disc from even playing in a PC drive.

Several copy protection schemes are available for CD-DA (digital audio) discs, ranging from the simple to sophisticated. The most popular protection scheme for digital audio discs is called SafeAudio by Macrovision. Macrovision won't explain exactly how SafeAudio works, but it purchased the technology from a company called TTR Technologies and patents filed by TTR describe the scheme in detail. According to the patents, the disc is deliberately recorded with grossly erroneous values (bursts of noise) in both the audio data and the codes, which would typically be used to correct these errors. When reading the disc, the normal error correction scheme fails, leaving small gaps in the music.

When this happens on a standard audio CD player, the gaps are automatically bridged by circuitry or code in the player, which looks at the audio data on either side of the gap and interpolates (guesses) the missing values. The CD drive in a PC can do the same thing, so the interpolation occurs only when playing CDs in an audio player mode. However, the drive in a PC does not perform this same interpolation when "ripping" the data—that is, copying it directly to a hard drive, another CD, or some other medium. In that case the unbridged gaps are heard as extremely loud clicks, pops, and noise. Both TTR and Macrovision claim that the interpolation that occurs when playing a SafeAudio disc is not discernable to the human ear, but many audio experts disagree. To an audiophile, the addition of any distortion or noise to the audio signal is unconscionable.

Even more rigorous protection can be added that can render the audio disc unplayable on a PC and even cause problems on audio players. Of course, the final problem is that you can't make legal backups of your music—something that is allowed by law.

For software (rather than audio), several protection schemes are used, although most are similar to one another. Again the most popular is by Macrovision, but for CD-ROMs it is called SafeDisc. As with SafeAudio, Macrovision purchased the technology from another company; in this case it was a company called C-Dilla.

SafeDisc works by first encrypting all the software code on the disc and then adding a routine to the code that looks for a unique authentication signature (called a *watermark*) which would have been added to the disc during the mastering process. When executed, the authentication code attempts to read the watermark on the disc. If the watermark is present, the main program code is unencrypted and executed. But if the watermark is not present, the program does not run. Because the watermark does not conform to the normal structures written to a CD, most CD burners can't duplicate it.

The authentication process basically requires that the original CD be present in the drive whenever the program is run. This, however, can be set up so that the original disc is required only during program installation, or it can be checked anytime the program is run, even if run from a hard disk. The latter is quite inconvenient because it requires you to have the original CD with you at all times to run the program.

To circumvent this type of protection, people have developed software that can fool the authentication code into believing the watermark is present. Some software even strips the authentication code from the software completely. Others have found ways to copy the watermark such that it would appear on any copies of the original CD. As with other forms of copy protection, it has been easily defeated and represents more of a nuisance to the legitimate user rather than to the thief.

To me these forms of protection cripple the software or music sufficiently that I refuse to purchase any copy-protected discs. My solution is to avoid the problem and purchase other software or music that is not encumbered by copy protection. Copy protection has been tried before (and failed) in the computer industry with floppies, and I feel we are going to see a repeat performance with CDs.

Note that virtually every single copy protection scheme has been defeated. Therefore, several programs are on the market (many of which can be downloaded for free) that easily copy so-called protected discs. If you do a search on "CD copy protection," you will find numerous links to sites that have information about how to back up these discs and the software with which to do it.

In the United States, the owner of a copyrighted work is allowed to copy that work for personal use under the 1976 doctrine of Fair Use. Because this appears to legalize making backups of both software and music, using specially designed software to copy any so-called uncopyable discs appears to also be completely legal. In fact, there is at least one case in court that might prove that the copy protection itself is illegal because it violates your right to make backups.

Recordable DVD Standards

The history of recordable DVD drives is a troubled one. It dates back to April 1997, when the DVD Forum announced specifications for rewritable DVD, DVD-RAM, and DVD-R. Later, it added DVD-RW to the mix. Dissatisfied with these standards, the industry leaders in optical recording and drives formed their own group called the DVD+RW Alliance and created another standard—DVD+R and DVD+RW.

In a war that brings back unhappy memories of the VHS/Beta struggle of the 1980s, as well as the problems in bringing DVD video to light, the computer and movie industries are locked in a struggle to see which enhancements to the basic DVD standard will win out. Table 13.27 compares the competing recordable DVD standards, and Table 13.28 breaks down the compatibilities between the drives and media.

Table 13.27 Recordable DVD Standards

Format	Introduced	Capacity	Compatibility
DVD-RAM	July '97	Up to 4.7GB per side	Incompatible with existing DVD drives unless they support the MultiRead2 standard
DVD-R/RW	July '97/Nov. '99	4.7GB per side	Readable by many existing DVD recorders/drives
DVD+R/RW	Mar. '01/May '01	4.7GB per side	Readable by most existing DVD recorders/drives, with enhancements for video and data recording

Table 13.28 DVD Drive and Media Compatibility

	Media (Discs)									
Drives	**CD-ROM**	**CD-R**	**CD-RW**	**DVD-Drive**	**DVD-ROM**	**DVD-R**	**DVD-RAM**	**DVD-RW**	**DVD+RW**	**DVD+R**
DVD-Video Player	R	?	?	R	—	R	?	R	R	R
DVD-ROM Drive	R	R	R	R	R	R	?	R	R	R
DVD-R Drive	R	R/W	R/W	R	R	R/W	—		R	R
DVD-RAM Drive	R	R	R	R	R	R	R/W	R	R	R
DVD-RW Drive	R	R/W	R/W	R	R	R/W	—	R/W	R	R
DVD+R/RW Drive	R	R/W	R/W	R	R	R	R	R	R/W	R/W*

R = Read *W = Write*

— = Will not read or write *? = MultiRead/MultiPlay drives will read*

**Some first-generation DVD+RW drives will not write DVD+R discs; see your drive manufacturer for an update or trade-in.*

As you can see from looking at both the horizontal rows and vertical columns of Table 13.28, DVD+RW drives are most compatible with other media, and the media they record is the most compatible with other drives. DVD+RW is currently winning out in the industry among all of these because it is among the least expensive, easiest to use, and the most compatible with existing and previous formats.

DVD-RAM

DVD-RAM is the rewritable DVD standard endorsed by Panasonic, Hitachi, and Toshiba. DVD-RAM uses a phase-change technology similar to that of CD-RW. Unfortunately, DVD-RAM discs can't be read by most standard DVD-ROM drives because of differences in both reflectivity of the media and the data format. (DVD-R, by comparison, is backward compatible with DVD-ROM.) DVD-ROM drives that can read DVD-RAM discs began to come on the market in early 1999 and follow the MultiRead2 specification. DVD-ROM drives and DVD-Video players labeled as MultiRead2 compliant are capable of reading DVD-RAM discs. See the section "MultiRead Specifications," earlier in this chapter, for more information.

The first DVD-RAM drives were introduced in spring 1998 and had a capacity of 2.6GB (single-sided) or 5.2GB (double-sided). DVD-RAM Version 2 discs with 4.7GB arrived in late 1999, and double-sided 9.4GB discs arrived in 2000. DVD-RAM drives typically read DVD-Video, DVD-ROM, and CD media. The current installed base of DVD-ROM drives and DVD-Video players can't read DVD-RAM media.

DVD-RAM uses what is called the wobbled land and groove recording method, which records signals on both the lands (the areas between grooves) and inside the grooves that are preformed on the disc. The tracks wobble, which provides clock data for the drive. Special sector header pits are prepressed into the disc during the manufacturing process as well. See Figure 13.14, which shows the wobbled tracks (lands and grooves) with data recorded both on the lands and in the grooves. This is unlike CD-R or CD-RW, in which data is recorded on the groove only.

The disc is recorded using phase-change recording, in which data is written by selectively heating spots in the grooves or on the lands with a high-powered laser. The DVD-RAM drive write laser transforms the film from a crystalline to an amorphous state by heating a spot, which is then rendered less reflective than the remaining crystalline portions. The signal is read as the difference of the laser reflection rate between the crystalline and amorphous states. The modulation and error correction codes are the same as for DVD-Video and DVD-ROM, ensuring compatibility with other DVD formats. For rewriting, a lower-powered laser reheats the spot to a lower temperature, where it recrystallizes.

Disc cartridges or caddies originally were required for both single- and double-sided discs but have now been made optional for single-sided discs. Double-sided discs must remain inside the caddy at all times for protection; however, single-sided discs can be taken out of the cartridge if necessary.

DVD-RAM specifications are shown in Table 13.29.

Table 13.29 DVD-RAM Specifications

Storage capacity	2.6GB single-sided; 5.2GB double sided
Disc diameter	80mm–120mm
Disc thickness	1.2mm (0.6mm×2: bonded structure)
Recording method	Phase change
Laser wavelength	650nm
Data bit length	0.41–0.43 microns
Recording track pitch	0.74 microns
Track format	Wobbled land and groove

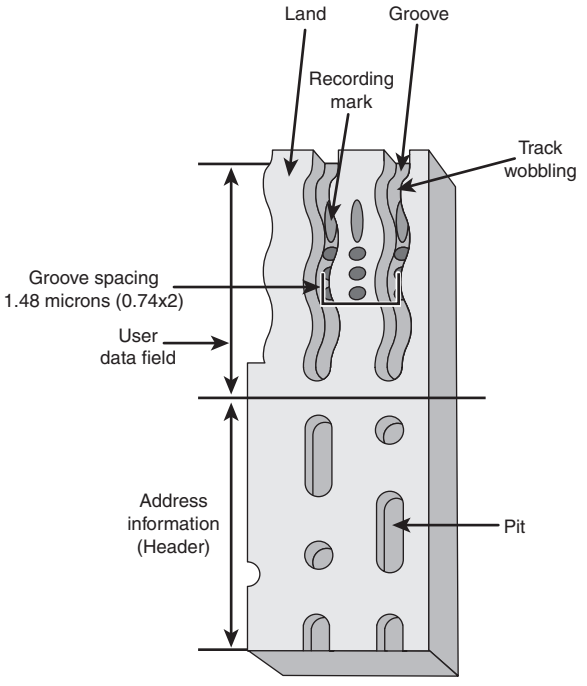

Figure 13.14 DVD-RAM wobbled land and groove recording.

DVD-R

DVD-R is a write-once medium very similar to CD-R, which was originally created by Pioneer and released by the DVD Forum in July 1997. DVD-R discs can be played on standard DVD-ROM drives.

DVD-R has a single-sided storage capacity of 4.7GB —about seven times that of a CD-R—and double that for a double-sided disc. These discs use an organic dye recording layer that allows for a low material cost, similar to CD-R.

To enable positioning accuracy, DVD-R uses a wobbled groove recording, in which special grooved tracks are pre-engraved on the disc during the manufacturing process. Data is recorded within the grooves only. The grooved tracks wobble slightly right and left, and the frequency of the wobble contains clock data for the drive to read, as well as clock data for the drive. The grooves are spaced more closely together than with DVD-RAM, but data is recorded only in the grooves and not on the lands (see Figure 13.15).

Table 13.30 has the basic specifications for DVD-R drives.

Table 13.30 DVD-R Specifications

Storage capacity	3.95GB single-sided; 7.9GB double-sided
Disc diameter	80mm–120mm
Disc thickness	1.2mm (0.6mm×2: bonded structure)
Recording method	Organic dye layer recording method
Laser wavelength	635nm (recording); 635/650nm (playback)

Table 13.30 Continued

Data bit length	0.293 microns
Recording track pitch	0.80 microns
Track format	Wobbled groove

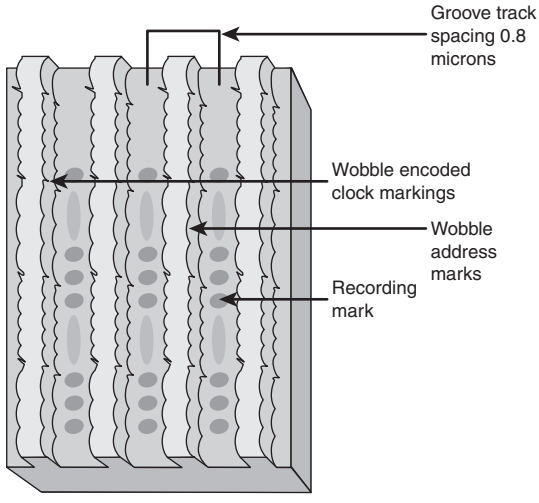

Figure 13.15 DVD-R wobbled groove recording.

DVD-RW

The DVD Forum introduced DVD-RW in November 1999. Created and endorsed mainly by Pioneer, DVD-RW is basically an extension to DVD-R just as CD-RW is an extension to CD-R. DVD-RW uses a phase-change technology and is somewhat more compatible with standard DVD-ROM drives than DVD-RAM. Drives based on this technology began shipping in late 1999, but they have achieved only moderate popularity because only one company manufactures these drives (Pioneer).

DVD+RW

DVD+RW, also called DVD Phase Change Rewritable, is rapidly becoming the premier DVD recordable standard because it is the least expensive, easiest to use, and most compatible with existing formats. It was developed and is supported by Philips, Sony, Hewlett-Packard, Mitsubishi Chemical, Ricoh, Yamaha, Verbatim, and Thompson, who are all part of an industry standard group called the DVD+RW Alliance (`http://www.dvdrw.com`). In addition, companies such as Ahead Software (Nero Burning ROM software) and Roxio (CD Creator and DirectCD software) have announced they are developing support software for DVD+RW. In fact, more than 50 independent software vendors and equipment manufacturers support DVD+RW, making it the most well supported of all the DVD rewritable formats.

DVD+RW drives are designed to work with both DVD+R (writable) and DVD+RW (rewritable) media. The +R discs can be written only once and are less expensive than the +RW discs.

DVD+RW is the only writable/rewritable format that provides full compatibility with existing DVD-Video players and DVD-ROM drives for both real-time video recording and random data

recording across PC and entertainment applications. DVD+RW is designed to not only be useful for PC data storage, but to also directly record video in the DVD-Video format. This is the breakthrough the recordable DVD industry has been waiting for, and as such, DVD+RW is destined to replace the VCR in consumer-level home recorders.

Some of the features of DVD+RW includes are as follows:

- Single-sided discs (4.7GB).
- Double-sided discs (9.4GB).
- Up to 4 hours video recording (single-sided discs).
- Up to 8 hours video recording (double-sided discs).
- Bare discs—no caddy required.
- 650nm laser (same as DVD-Video).
- Constant linear data density.
- CLV and CAV recording.
- Write speeds 1x–2.4x and higher.
- DVD-Video data rates.
- UDF (Universal Disc Format) file system.
- Defect management integral to the drive.
- Quick formatting.
- Uses same eight to sixteen modulation and error correcting codes as DVD-ROM.
- Sequential and random recording.
- Lossless linking (multiple recording sessions don't waste space).
- Spiral groove with radial wobble.
- After recording, all physical parameters comply with the DVD-ROM specification.

As consumer and PC applications for DVD continue to develop, DVD+RW provides the only recordable DVD format that seamlessly integrates into the consumer DVD-Video market as well as the PC DVD-ROM market, offering the best of both worlds. DVD+RW technology is very similar to CD-RW, and DVD+RW drives can read DVD-ROMs and all CD formats, including CD-R and CD-RW.

With DVD+RW, the writing process can be suspended and continued without a loss of space linking the recording sessions together. This increases efficiency in random writing and video applications. This "lossless linking" also enables the selective replacement of any individual 32KB block of data (the minimum recording unit) with a new block, accurately positioning with a space of 1 micron. To enable this high accuracy for placement of data on the track, the pre-groove is wobbled at a higher frequency. The timing and addressing information read from the groove is very accurate.

The quick formatting feature means you can pop a DVD+R or DVD+RW blank into the drive and almost instantly begin writing to it. The actual formatting is carried out in the background ahead of where any writing will occur.

Out of the three DVD rewritable formats that have been released, DVD+RW is the format that brings recordable DVD to the masses in both standalone home consumer units as well as integrated into newer PCs.

CD/DVD Software and Drivers

After you've physically installed the drive, you're ready for the last step—installing the drivers and other CD-ROM/DVD-ROM software. As usual, this process can be simple with a PnP operating system such as Windows 9x or later. In that case the drivers for Windows will automatically be installed. Things are different, however, if you need to access the drive after booting from a floppy, such as when installing an operating system, running diagnostics, or running DOS.

For a CD or DVD drive to function in a floppy (or CD) boot environment, several drivers might be necessary:

- *An ATAPI host adapter driver (not needed for SCSI drives).* This driver is included with your motherboard, or you can use the generic ATAPI drivers found on Windows 98 and later startup disks.
- *SCSI adapter drivers (not needed for ATAPI drives).* Most SCSI cards include these drivers, or you can use the generic versions included on Windows 98 and later startup disks.
- *MSCDEX.* Microsoft CD Extensions, which is included with DOS 6.0 and later. It is also built into Windows 95 and later as the CDFS VxD.

You will need one of the first two drivers (ATAPI or SCSI) as well as the third one for the drive to work in a floppy (or CD) boot environment. Generic ATAPI and SCSI drivers can be found on the Windows 98 and newer startup disks. Rather than mess with creating custom `CONFIG.SYS` and `AUTOEXEC.BAT` files, I recommend you merely boot from a Windows 98 or newer startup floppy because each time you boot from these, the proper drivers load and autodetect the CD/DVD drives, after which the drives are accessible.

Using a CD-ROM or DVD-ROM drive that conforms to the ATAPI specification under Windows does not require you to do anything. All the driver support for these drives is built into Windows 9x, including the ATAPI driver and the CDFS VxD driver.

If you are running a SCSI CD-ROM drive under Windows 9x, you still need the ASPI driver that goes with your drive. The ASPI driver for your drive usually comes from the drive manufacturer and is included with the drive in most cases. However, by arrangement with hardware manufacturers, Windows 9x typically includes the ASPI driver for most SCSI host adapters and also automatically runs the CDFS VxD virtual device driver. In some rare cases, you might have to install an updated driver that you have obtained from the manufacturer.

When you install a PnP SCSI host adapter in a Windows 9x system, simply booting the computer should cause the operating system to detect, identify, and install drivers for the new device. When the driver for the host adapter is active, the system should detect the SCSI devices connected to the adapter and again load the appropriate drivers automatically.

DOS SCSI Adapter Driver

For DOS users, of course, the installation process is not so easy. Each SCSI adapter model has a specific driver that enables communication between the PC and the SCSI interface. Documentation should also be included that walks you through the installation of the software.

Most SCSI adapters come with an installation program that automates the process of installing the appropriate ASPI drivers, both for the adapter and for the devices connected to the SCSI bus. However, you can manually add the SCSI device driver to your `CONFIG.SYS` file. In the `CONFIG.SYS` file, add the name and path of the appropriate driver with the `DEVICE=` command (replace `C:\DRIVERS` with the actual location of your files and `MYSCSI.SYS` with the actual name of your SCSI driver):

```
DEVICE=C:\DRIVERS\MYSCSI.SYS
```

C:\DRIVERS is the subdirectory into which you copied the SCSI ASPI device drivers. Some drivers have option switches or added commands that, for example, enable you to view the progress of the driver being loaded.

DOS ATAPI CD-ROM Device Driver

This driver should be a part of your basic installation kit as well. If not, contact the drive's manufacturer for the proper device driver for your SCSI card.

The device driver should come with an installation program that prompts you for the memory I/O address for the SCSI adapter to which you've connected the CD-ROM drive. This device driver enables the adapter to communicate with the drive through the SCSI bus. Installation programs add a line similar to the following to your CONFIG.SYS file (replace MYCDROM.SYS with the actual name of your CD-ROM driver file and C:\DRIVERS with the actual location of your files):

```
DEVICE=C:\DRIVERS\MYCDROM.SYS /D:mscd001
```

C:\DRIVERS is the subdirectory that contains the driver MYCDROM.SYS, which is the driver for your specific CD-ROM drive.

Note the /D:mscd001 option after the preceding statement. This designation, called the device signature, identifies this CD-ROM driver as controlling the first (001), and only, CD-ROM drive on the system. This portion of the device driver statement is for the Microsoft DOS Extensions driver, which designates CD-ROM drives in this fashion. In fact, you could use any designation here, as long as the MSCDEX command line uses the same one.

MSCDEX: Adding CDs to DOS/Win3.x

The Microsoft CD Extensions for DOS enable the DOS operating system (and by extension, Windows 3.x) to identify and use data from CD-ROMs attached to the system. The original DOS operating system had no provisions for this technology, so "hooks" or handling of this unique media are not part of the basic operating environment. Using these extensions is convenient for all involved, however. As CD-ROM technology changes, the MSCDEX can be changed independently of DOS. For example, most Photo CD, multiple-session CD-ROM drives require MSCDEX.EXE version 2.21 or higher, which has been modified from earlier versions to accommodate the newer CD-ROM format.

MSCDEX.EXE should be in your software kit with your drive. If not, you can obtain the latest copy directly from Microsoft. If you are a registered user of DOS or Windows 3.1, MSCDEX.EXE is free. Read the licensing agreement that appears on the disc or in your manual concerning the proper licensing of the MSCDEX files.

Your installation software should add a line similar to the following to your AUTOEXEC.BAT file:

```
C:\WINDOWS\COMMAND\MSCDEX.EXE /d:mscd001
```

C:\WINDOWS\COMMAND is the directory in which the MSCDEX.EXE file is located by default with Windows 9x and later; with MS-DOS and Windows 3.1, it could be located in the \DOS directory or in the directory containing the CD-ROM drivers. The /d:mscd001 portion of the command line supplies the MSCDEX extension with the device signature defined in the CD-ROM device driver of your CONFIG.SYS file.

Note

The MSCDEX and CD-ROM device signatures must match. The defaults that most installations provide are used in this example. As long as the two names are the same, the drivers can find one another.

As long as you have these three drivers—the SCSI adapter driver, the CD-ROM driver, and the DOS CD extensions—loaded properly in your system, the CD-ROM drive will operate as transparently as any other drive in your system.

Table 13.31 lists the options you can add to the MSCDEX.EXE command line.

Table 13.31 MSCDEX Command-Line Options

Switch	Function
`/V`	Called Verbose; when this option is added to the command line, it displays information about memory allocation, buffers, drive letter assignments, and device driver names on your screen at boot time.
`/L:<letter>`	Designates which DOS drive letter you want to assign to the drive. For example, `/L:G` assigns the drive letter G: to your CD-ROM drive. Two conditions apply: First, you must not have another drive assigned to that letter; second, your `lastdrive=` statement in your `CONFIG.SYS` file must be equal to or greater than the drive letter you're assigning.
`/M:<buffers>`	Enables you to buffer the data from the CD-ROM drive. This is useful if you want faster initial access to the drive's directory. Buffers of 10–15 are more than enough for most uses. Any more is overkill. Each buffer is equal to 2KB of memory. So a `/M:10` buffer argument, for example, would take 20KB of memory. This does not significantly increase the overall performance of the drive, just DOS's initial access to the drive and the access of large data blocks. With no `/M:` argument added, MSCDEX adds six buffers as a default. That might be fine for most PCs and CD-ROM drives.
`/E`	Loads the aforementioned buffers into DOS high memory, freeing up space in the conventional 640KB. Early versions of MSCDEX—anything below version 2.1—do not load into extended memory. You must have DOS 5.0 for this option to load.
`/K`	Provides Kanji (Japanese) language support.
`/S`	Enables you to share your CD-ROM drive on a peer-to-peer network, such as Windows for Workgroups.

Note that Windows 9x uses a built-in CDFS driver that takes the place of MSCDEX. It is configured through the Windows 9x Registry and requires no `AUTOEXEC.BAT` command. USB-based CD-ROM/CD-R/CD-RW drives are also configured through the Windows 9x Registry and use no `CONFIG.SYS` or `AUTOEXEC.BAT` commands.

CD-ROM Support in Windows 9x and Windows NT 4.0

As stated earlier, Windows 9x/Me and Windows NT/2000 include virtually all the drivers you will need to run your optical drive, making the software installation automatic. Windows automatically recognizes most ATAPI drives, and with the addition of the appropriate drive-specific ASPI driver, most SCSI drives as well.

There are several new capabilities with CDs and DVDs in Windows 9x/NT. The most dramatic is the Autoplay feature, which is available on Windows 95/98 and some versions of Windows NT 4.0.

Autoplay is a feature integrated into Windows 9x that enables you to simply insert a disc into the drive, and Windows will automatically run it without any user intervention. It also detects whether that particular disc has already been installed on your system, and if not, automatically starts the install program. If the disc has already been installed, it starts the application program on the disc.

The Autoplay feature is simple. When you insert a disc, Windows 9x automatically spins it and looks for a file called `AUTORUN.INF`. If this file exists, Windows 9x opens it and follows the instructions contained within. As you can see, this Autoplay feature works only on discs that have this file. Most software companies are now shipping CD-ROM and DVD-ROM titles that incorporate the Autoplay feature.

Tip

You can disable the Autoplay feature for all CD-ROMs by opening the Windows Control Panel, using the System Properties applet to access the Device Manager page, highlighting your CD-ROM drive, and clicking the Properties button. The Properties dialog box for the drive has a Settings page that contains an Auto Insert Notification check box. Clearing this box prevents the operating system from processing the `AUTORUN.INF` file.

If you want to use Autoplay for some CDs but not others, hold down the Shift key when inserting a CD you don't want to Autoplay.

All Windows versions after 3.x include an application called Media Player (the most recent version, 8.x, is included with Windows XP). This application enables you to play audio CDs in your drive while working at the computer. The CD Player features graphical controls that look like a standard audio CD-ROM drive and even has advanced features found in audio drives, such as random play, programmable playback order, and the capability to save play list programs.

MS-DOS Drivers and Windows 9x

Many users have discovered at a very unfortunate time that their CD-ROM drives didn't come with MS-DOS drivers: when their Windows 9x system wouldn't start up. All too often, the "cure" for a "dead" Windows 9x system is a complete reinstallation from the Windows 9x CD, to replace defective files and settings with new copies. Of course, if Windows isn't working, its 32-bit CD-ROM device drivers aren't working either. And, if you don't have your `CONFIG.SYS` and `AUTOEXEC.BAT` files and the files listed earlier either, you can't reload Windows! You should have a bootable disk ready that has the appropriate drivers included to enable you to rebuild your Windows 9x installation in case of emergencies.

If you have Windows 98 or later, the Emergency Startup disk you create during installation or later already has the appropriate drivers, `AUTOEXEC.BAT`, and `CONFIG.SYS` included to run most popular SCSI and ATAPI-based CD-ROMs. However, a Windows 95 bootable disk doesn't include the `AUTOEXEC.BAT`, `CONFIG.SYS`, or drivers; you must add these yourself (see the next section).

Note

If you can't find any references to the MS-DOS drivers needed for your CD-ROM drive on your Windows 9x computer, check for an installation disk that might have been shipped with the drive. To install the CD-ROM device driver files you need, use that disk to perform an MS-DOS/Windows 3.1 installation, which adds the appropriate lines to your `CONFIG.SYS` and `AUTOEXEC.BAT` files and copies the drivers to your system.

Creating a Bootable Floppy with CD-ROM Support

If your system BIOS is a version from 1998 or later, most likely it has "El Torito" support, which means it supports booting from a bootable CD. The El Torito name comes from the Phoenix Software/IBM standard that apparently was discussed at an El Torito restaurant near the Phoenix Software offices. What El Torito means is that you can boot from CDs, which opens up several new possibilities, including creating bootable CD rescue discs, booting from newer OS discs when installing to new systems, creating bootable diagnostics and test CDs, and more.

To create a bootable CD, you need a bootable floppy that contains the drivers to support your CD drive in DOS mode (sometimes called real-mode drivers).

Tip

Optionally, you can use a Windows 98/Me startup floppy because these have the DOS-level CD-ROM support already configured and installed. You can even use a Windows 98/Me startup disk to boot a Windows 95 system, so getting a disk from a 98/Me system is definitely the easiest way to proceed. If that is not an option, you can add the CD-ROM support to the Windows 95 or any DOS startup disk.

Test your boot floppy (with CD-ROM drivers) by first booting to the floppy. Then, with a CD containing files in the CD-ROM drive, see whether you can change to the CD-ROM drive and read a directory of the files (try the `DIR` command). The CD usually is the next drive letter after your last hard drive letter. For example, if your last hard drive letter is C:, the CD-ROM will be D:.

If you can display a directory listing of the CD after booting from the floppy, your CD-ROM drivers are properly loaded.

Creating a Rescue CD

Several programs on the market today allow you to make a compressed image file of the contents of any drive. These programs, such as the Ghost program sold by Symantec or PowerQuest's Drive Image, enable you to lock in the condition of any drive as of a particular time.

This enables you to create an image file of your system when it's working and use the image-restore feature to reset your system when it fails.

The perfect place to store a compressed image file is on a CD-R. At a minimum, your rescue disk should contain the compressed image file (a 737MB, 80-minute CD-R/RW could contain the equivalent of a nearly 1.5GB drive's normal contents if the maximum compression option is used). It's also desirable to place a copy of the image-restore program on the CD. Mastering this type of rescue CD is done exactly the same as a conventional CD mastering process. To use the rescue CD, you must boot your system with drivers that allow the CD-ROM drive to work, run the restore program to read the data from the CD, and overwrite the drive's existing contents.

If you're looking for a single-CD solution to rescuing your system, one that won't require you to lug around a bootable floppy disk, you can burn a rescue CD that is bootable all by itself.

Making a Bootable CD for Emergencies

A little-known capability to PC users is that they can create their own versions of what is standard with more and more new computers: a bootable CD that can be used to start up a system and restore it to a previously saved state.

The minimum requirements for a bootable CD include

- *A system in which the CD/DVD can be designated as a boot drive.* Check your BIOS under Advanced Setup or similar options. Recent and current BIOS code supplied by AMI, Award Software, and Phoenix Technologies typically support the CD as a bootable device.
- *A CD-R or CD-RW drive and either CD-R or CD-RW media.*
- *Recording software that allows creation of a bootable CD.* Most modern CD recording software, such as NERO Burning ROM or Roxio CD Creator, support creating bootable CDs. If your current CD-recording software lacks this option, you must upgrade to something that does.
- *A floppy disk containing your operating system boot files.*

ATAPI Drives Are Bootable

Most ATAPI drives connected to a motherboard ATA interface can be used as bootable devices if the BIOS permits it. If your CD-ROM is connected to a sound card, this procedure won't work. If your CD-ROM is connected to a SCSI interface, you'll need a SCSI interface with a BIOS chip that permits booting as well as a bootable CD.

Check your BIOS Setup for a page on which boot devices are listed to see whether yours supports a CD-ROM drive as a bootable device.

The basic procedure for creating a bootable CD is as follows:

1. Create a bootable floppy for the operating system you want to install on the CD.
2. Get a blank CD-R, and place it into your CD-R/CD-RW drive.
3. Start your mastering software.
4. Under disc layout, ensure that ISO 9660 is selected. This CD format doesn't permit long filenames, so be sure that any additional files you add to the CD have no more than eight characters plus up to three characters for the filename extension.
5. Make sure the bootable option is enabled in the disc layout.
6. When prompted, insert the floppy disk containing boot files into the A: drive.
7. These files are copied to your CD layout. Note that the names of these files are not the same as the normal operating system boot files. The files are called `BOOTCAT.BIN` and `BOOTIMG.BIN`.
8. Add any additional files (image files, operating system install files, and so on) you want to the layout.
9. Start the CD creation process.
10. When the process is completed, view the contents of the finished CD-R.
11. Close your mastering program, saving the layout if you desire.
12. Insert the bootable CD you just created into your CD-ROM drive.
13. Restart the computer and see whether your system boots from the CD.

If you follow these directions, you will discover that the CD-ROM disc appears as both drive A: and another letter. A: is the floppy image you copied during the creation process, whereas all the other files show up on the main CD drive letter.

Caring for Optical Media

Some people believe that optical discs and drives are indestructible when compared to their magnetic counterparts. Actually, modern optical drives are far less reliable than modern hard disk drives. Reliability is the bane of any removable media, and CD-ROMs and DVD-ROMs are no exception.

By far the most common causes of problems with optical discs and drives are scratches, dirt, and other contamination. Small scratches or fingerprints on the bottom of the disc should not affect performance because the laser focuses on a point inside the actual disc, but dirt or deep scratches can interfere with reading a disc.

To remedy this type of problem, you can clean the bottom surface of the CD with a soft cloth, but be careful not to scratch the surface in the process. The best technique is to wipe the disc in a radial fashion, using strokes that start from the center of the disc and emanate toward the outer edge. This way, any scratches will be perpendicular to the tracks rather than parallel to them, minimizing the interference they might cause. You can use any type of solution on the cloth to clean the disc, so long

as it will not damage plastic. Most window cleaners are excellent at removing fingerprints and other dirt from the disc and don't damage the plastic surface.

If your disc has deep scratches, they can often be buffed or polished out. A commercial plastic cleaner such as that sold in auto parts stores for cleaning plastic instrument cluster and tail-lamp lenses is very good for removing these types of scratches. This type of plastic polish or cleaner has a very mild abrasive that polishes scratches out of a plastic surface. Products labeled as cleaners usually are designed for more serious scratches, whereas those labeled as polishes are usually milder and work well as a final buff after using the cleaner. Polishes can be used alone if the surface is not scratched very deeply.

Most people are careful about the bottom of the disc because that is where the laser reads, but the top is actually more fragile! This is because the lacquer coating on top of the disc is very thin, normally only 6–7 microns (0.24–0.28 thousandths of an inch). If you write on a disc with a ball point pen, for example, you will press through the lacquer layer and damage the reflective layer underneath, ruining the disc. Also, certain types of markers have solvents that can eat through the lacquer and damage the disc as well. You should write on discs only with felt tip pens that have compatible inks, such as the Sharpie or Staedtler Lumocolor brand, or other markers specifically sold for writing on CDs. In any case, remember that scratches or dents on the top of the disc are more fatal than those on the bottom.

Read errors can also occur when dust accumulates on the read lens of your CD-ROM drive. You can try to clean out the drive and lens with a blast of "canned air" or by using a drive cleaner (which can be purchased at most music stores that sell audio CDs).

If your discs and your drive are clean, but you still can't read a particular disc, your trouble might be due to disc capacity. Many older CD-ROM drives are unreliable when they try to read the outermost tracks of newer discs where the last bits of data are stored. You're more likely to run into this problem with a CD that has lots of data—including some multimedia titles. If you have this problem, you might be able to solve it with a firmware or driver upgrade for your CD-ROM drive, but the only solution might be to replace the drive.

Sometimes too little data on the disc can be problematic as well. Some older CD-ROM drives use an arbitrary point on the disc's surface to calibrate their read mechanism, and if there happens to be no data at that point on the disc, the drive will have problems calibrating successfully. Fortunately, this problem usually can be corrected by a firmware or driver upgrade for your drive.

Many older drives have had problems working under Windows 9x. If you are having problems, contact your drive manufacturer to see whether a firmware or software-driver upgrade is available that might take care of your problem. With new high-speed drives available for well under $100, it might not make sense to spend any time messing with an older drive that is having problems. It might be more cost-effective to upgrade to a new drive instead.

If you are having problems with only one particular disc and not the drive in general, you might find that your difficulties are in fact caused by a defective disc. See whether you can exchange the disc for another to determine whether that is indeed the cause.

Troubleshooting Optical Drives

Failure Reading a CD

If your CD-ROM drive fails to read a CD, try the following solutions:

- Check for scratches on the CD data surface.
- Check the drive for dust and dirt; use a cleaning CD.

- Make sure the drive shows up as a working device in System Properties.
- Try a CD that you know works.
- Restart the computer (the magic cure-all).
- Remove the drive from Device Manager in Windows 9x, allow the system to redetect the drive, and then reinstall the drivers (if PnP-based system).

Failure to Read CD-R, CD-RW Discs in CD-ROM or DVD Drive

If your CD-ROM or DVD drive fails to read CD-R and CD-RW discs, try the following solutions:

- Check compatibility; some very old 1x CD-ROM drives can't read CD-R media. Replace the drive with a newer, faster, cheaper model.
- Many early-model DVD drives can't read CD-R, CD-RW media; check compatibility.
- The CD-ROM drive must be MultiRead compatible to read CD-RW because of the lower reflectivity of the media; replace the drive.
- If some CD-Rs but not others can be read, check the media color combination to see whether some color combinations work better than others; change the brand of media.
- Packet-written CD-Rs (from Adaptec DirectCD and backup programs) can't be read on MS-DOS/Windows 3.1 CD-ROM drives because of the limitations of the operating system.

ATAPI CD-ROM Drive Runs Slowly

If your ATAPI CD-ROM drive performs poorly, check the following items:

- Check the cache size in the Performance tab of the System Properties control panel. Select the quad-speed setting (largest cache size).
- Check to see whether the CD-ROM drive is set as the slave to your hard disk; move the CD-ROM to the secondary controller if possible.
- Your PIO (Programmed I/O) or UDMA mode might not be set correctly for your drive in the BIOS; check the drive specs and use autodetect in BIOS for the best results (see Chapter 5, "BIOS").
- Check that you are using busmastering drivers on compatible systems; install the appropriate drivers for the motherboard's chipset and the operating system in use. See the section "Direct Memory Access and Ultra-DMA," earlier in this chapter.
- Check to see whether you are using the CD-ROM interface on your sound card instead of the ATA connection on the motherboard. Move the drive connection to the ATA interface on the motherboard and disable the sound card ATA if possible to free up IRQ and I/O port address ranges.
- Open the System Properties control panel and select the Performance tab to see whether the system is using MS-DOS Compatibility Mode for CD-ROM drive. If all ATA drives are running in this mode, see `www.microsoft.com` and query on "MS-DOS Compatibility Mode" for a troubleshooter. If only the CD-ROM drive is in this mode, see whether you're using CD-ROM drivers in `CONFIG.SYS` and `AUTOEXEC.BAT`. Remove the lines containing references to the CD-ROM drivers (don't actually delete the lines—`REM` them), reboot the system, and verify that your CD-ROM drive still works and that it's running in 32-bit mode. Some older drives require at least the `CONFIG.SYS` driver to operate.

Poor Results When Writing to CD-R Media

If you are having problems successfully writing data to a CD, see "How to Reliably Record CDs," earlier in this chapter.

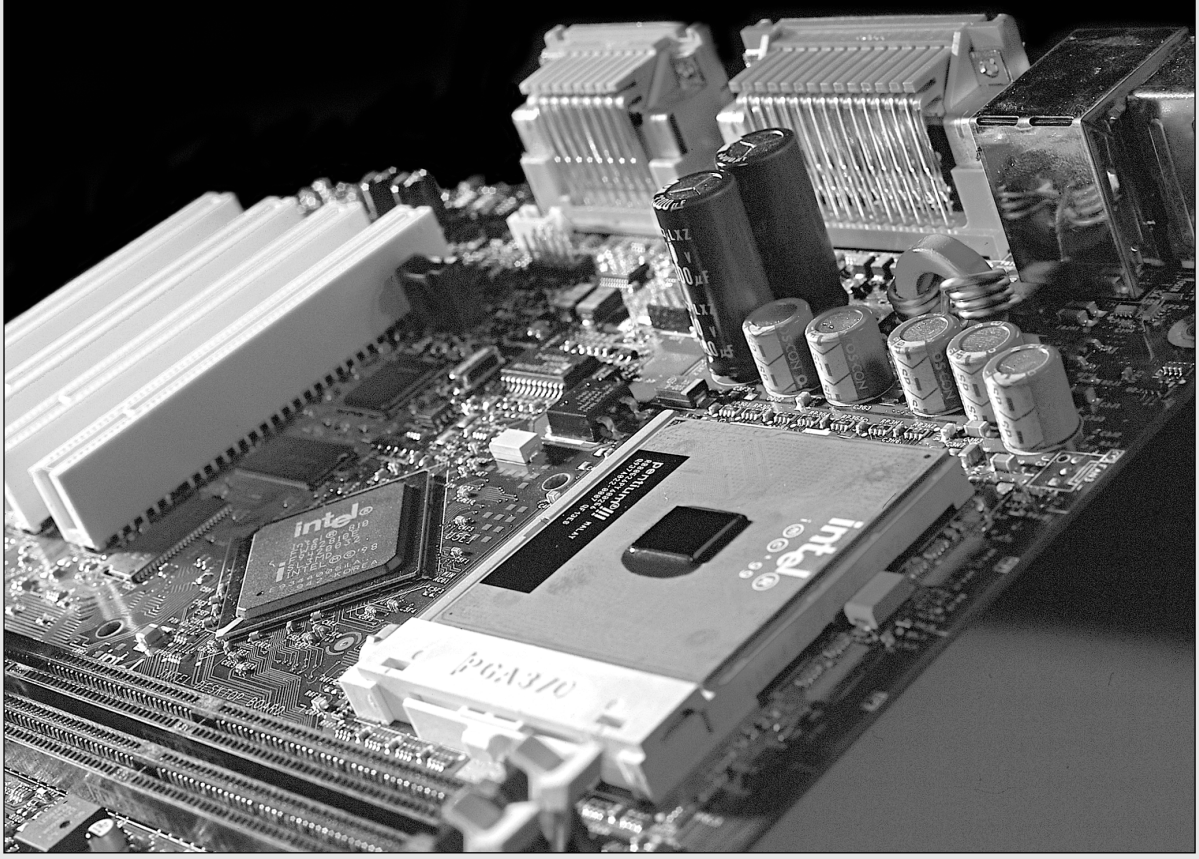
Trouble Reading CD-RW Discs on CD-ROM

If you can't read CD-RW discs in your CD-ROM, check the vendor specifications to see whether your drive is MultiRead compliant. Some drives are not compliant.

If your drive is MultiRead compliant, try the CD-RW disc on a known-compliant CD-ROM drive (a drive with the MultiRead feature).

Trouble Reading CD-R Discs on DVD Drive

If your DVD drive can't read a CD-R disc, check to see that the drive is MultiRead2 compliant because non-compliant DVDs can't read CD-R media. Newer DVD drives generally support reading CD-R media.



Trouble Making Bootable CDs

If you are having problems creating a bootable CD, try these possible solutions:

- Check the contents of the bootable floppy disk from which you copied the boot image. To access the entire contents of a CD, a bootable disk must contain CD-ROM drivers, `AUTOEXEC.BAT`, and `CONFIG.SYS`.
- Use the ISO 9660 format. Don't use the Joliet format because it is for long-filename CDs and can't boot.
- Check your system's BIOS for boot compliance and boot order; the CD-ROM should be listed first.
- SCSI CD-ROMs need a SCSI card with BIOS and bootable capability as well as special motherboard BIOS settings.

CHAPTER 14

Physical Drive Installation and Configuration

Installing All Types of Drives

This chapter covers the actual installation of hard drives, optical drives (CD/DVD), floppy drives, and tape drives. This includes everything from preparing the components to setting jumpers to installing the actual cabling and physical installation. I also dig into some initial system software configuration issues, right up to the point of installing the operating system. From that point on, the steps you take depend on which operating system you are installing.

For more information on drive interfaces, magnetic storage, drive operation, and operating system issues, see the following chapters:

- Chapter 7, "The IDE Interface"
- Chapter 8, "The SCSI Interface"
- Chapter 9, "Magnetic Storage Principles"
- Chapter 10, "Hard Disk Storage"
- Chapter 11, "Floppy Disk Storage"
- Chapter 12, "High-Capacity Removable Storage"
- Chapter 13, "Optical Storage"
- Chapter 17, "I/O Interfaces from Serial and Parallel to IEEE-1394 and USB"

Although most of the drives you would install in a PC are covered here, the primary emphasis is on hard disks and other devices using either ATA (IDE) or SCSI interfaces. For USB or FireWire (IEEE-1394) devices, see Chapter 17.

Hard Disk Installation Procedures

This section describes the hard disk drive installation process, particularly the configuration, physical installation, and formatting of a hard disk drive.

To install a hard drive in a PC, you must perform some or all of the following procedures:

- Configure the drive.
- Configure the host adapter (if used).
- Physically install the drive.
- Configure the system to recognize the drive.
- Partition the drive (FDISK, DISKPART, or SETUP).
- High-level format the partitions (FORMAT or SETUP).

As you perform the procedure, you might need to know various details about the hard disk drive, host adapter (if used), and system ROM BIOS, as well as many of the other devices in the system. This information usually appears in the various manuals or reference sheets that come with these devices. When you purchase these items, be sure the vendor includes any documentation that came with the original components. (Many do not include the manuals unless you ask for them.) For most equipment sold today, you will get enough documentation from the vendor to enable you to proceed.

If you are like me, however, and want all the technical documentation on the device, you should contact the original manufacturer of the device and order the technical specification manual. For example, if you purchase a system that comes with a particular ATA drive, the seller probably will give you

some limited information on the drive, but not nearly the amount that the technical manual for the drive provides. To get this documentation, you normally download it from the drive manufacturer's Web site. The same rule applies for any of the other components in most of the systems sold today. I find the OEM technical manuals essential in providing the highest level of technical support possible.

For reference, you can look up the hard disk manufacturer names in the Vendor List on the DVD-ROM; you will find numbers to call for technical support, as well as URLs for their Web sites.

Note

You also will find a drive specification database on the DVD. This database contains an exhaustive list of drive specs for thousands of drives. If you don't have ready access to your drive specs, check out this searchable database.

Drive Configuration

Before you physically install a hard disk drive in the computer, you must ensure that it is properly configured. For an ATA/IDE drive, this generally means designating the drive as a master/slave or using the Cable Select (CS) feature and a special cable to determine the relationship. For SCSI drives, you must set the device's SCSI ID and possibly its SCSI bus termination state.

◀◀ These procedures are covered in "The IDE Interface," p. 491, and "The SCSI Interface," p. 537.

Host Adapter Configuration

Older hard disk drive types used separate disk controller cards you had to install in a bus slot. The ATA and SCSI hard disk drives used in today's PCs, however, have the disk controller integrated into the drive assembly. For ATA drives, the I/O interface is nearly always integrated into the system's motherboard, and you configure the interface through the BIOS Setup. No separate host adapter exists; therefore, if you have an ATA drive, you can proceed to the section "Physical Installation" later in this chapter. Some systems might use ATA/IDE adapters in lieu of the built-in interface. This is because some of the motherboard-integrated ATA interfaces might not support the faster modes (such as Ultra-ATA/33 through Ultra-ATA/133) that most newer drives can use. In most cases, I would recommend upgrading the motherboard rather than getting an ATA host adapter because a new motherboard has other benefits and the cost isn't much higher.

SCSI drives, however, usually require a host adapter card you must install in a bus slot like any other card. A few motherboards have integrated SCSI adapters, but these are rare. Configuring a SCSI host adapter card involves setting the various system resources the adapter requires. As with most expansion cards, a SCSI host adapter requires some combination of the following system resources:

- Boot ROM address (optional)
- Interrupt request (IRQ)
- Direct Memory Access (DMA) channel
- I/O port address

Not all adapters use every one of these resources, but some might use them all. In most cases with modern plug-and-play adapters and systems, the BIOS and your operating system automatically configure these resources. The computer sets the required hardware resource settings to values that do not conflict with other devices in the computer.

◀◀ See "Plug and Play BIOS," p. 408.

Note

A detailed list of PnP device IDs is included in the Technical Reference section of the DVD included with this book.

If your hardware or operating system does not support Plug and Play, you must manually configure the adapter to use the appropriate resources. Some adapters provide software that enables you to reconfigure or change the hardware resources, whereas others might use jumpers or DIP switches on the adapter card.

◀◀ See "System Resources," p. 324.

The ATA interface driver is part of the standard PC BIOS, which enables booting from an ATA drive. The BIOS provides the device driver functionality the system needs to access the drive before any files can be loaded from disk. However, a SCSI interface driver is not part of the standard PC BIOS, so most SCSI host adapters have their own onboard ROM BIOS that enables SCSI drives to function as bootable devices.

Note

Although standard ATA drivers are provided with Windows, this interface is typically built into the motherboard chipset South Bridge or I/O Controller Hub (ICH) component, and it usually requires that specific chipset drivers be loaded. If you are using a motherboard that is newer than your operating system version (for example, a new board purchased in late 2002 with Windows XP), be sure you install the chipset drivers that came with your motherboard immediately after installing Windows. If the board is older than the OS, the chipset drivers will most likely be present on the OS installation CD; however, it is still a good idea to update to the latest chipset drivers immediately after the OS installation.

Use of the SCSI BIOS is usually optional. If you are not booting from a SCSI drive, you can leave the BIOS on the card disabled and merely install the appropriate device driver to access the SCSI devices. Most host adapters have switches, jumpers, or configuration software you can use to enable or disable SCSI BIOS support.

In addition to providing boot functionality, the SCSI BIOS can provide many other functions, including any or all of the following:

- Low-level formatting
- Drive-type (parameter) control
- Host adapter configuration
- SCSI diagnostics
- Support for nonstandard I/O port addresses and interrupts

If the adapter's onboard BIOS is enabled, it uses specific memory address space in the upper memory area (UMA). The UMA is the top 384KB in the first megabyte of system memory. It is divided into three areas of two 64KB segments each, with the first and last areas being used by the video adapter circuits and the motherboard BIOS, respectively. Segments C000h and D000h are reserved for use by adapter ROMs, such as those found on disk controllers or SCSI host adapters.

Note

You must ensure that any adapters using space in these segments of the UMA (upper memory area) do not overlap with another adapter that uses this space. No two adapters can share this memory space. Most adapters have software, jumpers, or switches that can adjust the configuration of the board and change the addresses it uses to prevent conflict.

Physical Installation

The procedure for the physical installation of a hard disk drive is much the same as that for installing any other type of drive. You must have the correct screws, brackets, and faceplates for the specific drive and system before you can install the drive.

Some computer cases require plastic or metal rails that are secured to the sides of a hard disk drive so it can slide into the proper place in the system (see Figure 14.1). Other case designs have drive bays that directly accept the drive via screws through the side supports and no other hardware is necessary, whereas others use a cage arrangement where you first install the drives into a cage and then slide the cage into the case (see Figure 14.2). If your case uses rails or a cage, these are usually included with the case. With the proper mounting mechanism supplied via the case, all you need is the bare drive to install.

Because cables can vary for both ATA and SCSI interfaces, be sure you have the proper cable for both your drive and controller. For example, to run ATA-66 or faster modes (through ATA-133), you need a special 80-conductor cable that supports the CS feature. This cable is also recommended if you are running Ultra-ATA/33, and it works for all slower modes as well. To determine whether your cable has 40 or 80 conductors, simply count the ridges on the ribbon cable—each ridge contains a conductor (wire). Another indication is that the 80-conductor cable typically has the motherboard connector end color-coded blue, and the master and slave drive connectors colored-coded black and gray, respectively.

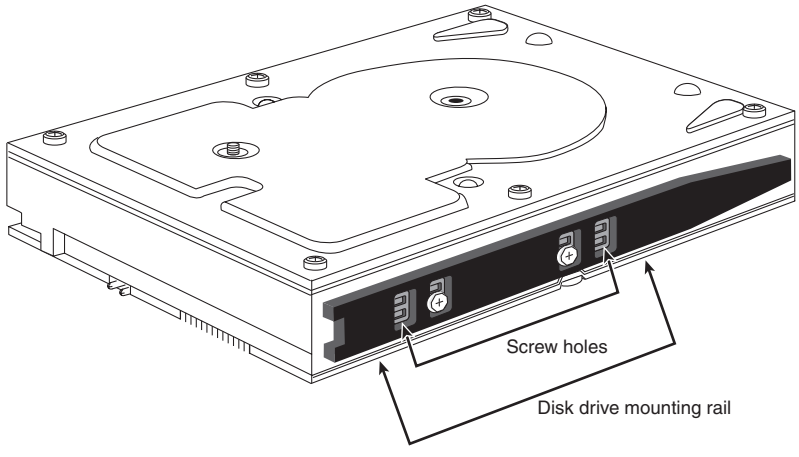


Figure 14.1 A typical 3 1/2" hard disk with mounting rails for a 3 1/2" drive bay.

If you need additional drive-mounting hardware not included with either your case or the drive, several companies that specialize in drive-mounting brackets, cables, and other hardware accessories are listed in the Vendor List (on the DVD). If you intend to install a 3 1/2" hard drive in a 5 1/4" drive bay, you need yet another type of mounting bracket (as shown in Figure 14.3). Many 3 1/2" hard drives come with these brackets, or one might be supplied with your case or chassis.

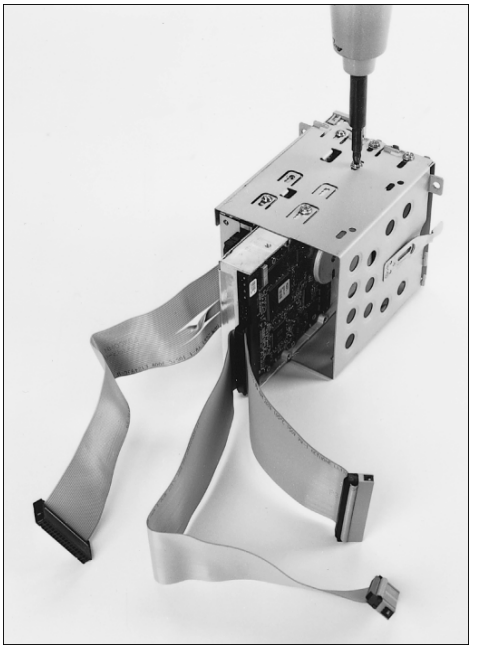

Figure 14.2 A typical hard disk mounted in a removable drive cage.

Note

You should also note the length of the drive cable itself when you plan to add a hard disk drive. It can be very annoying to assemble everything you think you'll need to install a drive and then find that the drive cable is not long enough to reach the new drive location. You can either try to reposition the drive to a location closer to the interface connector on the host adapter or motherboard or just get a longer cable. ATA/IDE cables are limited to 18" in overall length according to the standard; shorter is fine, but longer ones can cause signal integrity problems. This is most important if your drive is going to use the faster ATA-33 through ATA-133 modes. Using a cable that is too long causes timing errors and signal degradation, possibly corrupting the data on your drive. I see many 24"–36" cable assemblies being sold or used in systems; you are asking for trouble if you violate the 18" maximum-length specification.

Different faceplate, or bezel, options are also available. Make sure you have the correct bezel for your application. Some systems, for example, do not need a bezel; if a bezel exists on the drive, you must remove it.

Caution

Be sure you use only the screws that come with your new drive. Many drives come with special short-length screws that may have the same size thread as other screws you might use in your system, but that should not be interchanged. If you use screws that are too long, they might protrude too far into the drive casing and cause problems.

Figure 14.3 A typical bracket used to mount a 3 1/2" drive in a 5 1/4" drive bay. The bracket is screwed to the drive and then mounted in the bay by using screws or rails, as determined by the case.

The step-by-step procedures for installing a hard drive are as follows:

1. Check your computer for an unused ATA/IDE connector. Typical Pentium-class and newer PCs have two ATA/IDE connectors, allowing for up to four ATA/IDE devices.

   You might need an additional cable if both master and slave connectors are used on the primary cable and you are adding a third device.

Tip

Usually it is best for performance to keep devices that will be simultaneously active, such as hard drives and optical drives, on separate cables.

2. Double-check the pin configuration and cable type. The colored (normally red or red-flecked) stripe on one edge of the cable goes to pin 1 of the hard drive's data connector. Most cables and drive connectors are keyed to prevent improper (backward) installation, but many are not. Keying can be done via missing and plugged pins, a ridge on one side of the connector, or both. One tip to note is that pin 1 on the drive connector is almost always oriented nearest to the power connector.

Tip

Newer ATA drives that operate in the faster Ultra-DMA modes (ATA-66 through ATA-133) require a special 80-conductor cable, whereas lesser drives can use a 40-conductor cable. Note that you can always use the superior 80-conductor cable for slower drives, so normally that is all I recommend purchasing. SCSI drives use either 50-pin or 68-pin (wide) cables.

3. Configure the drive jumpers. If the drive is ATA/IDE and you are using a cable that supports CS, you must set the CS jumper on any drives connected to that cable. Otherwise, you must set the drives on the cable as either master or slave. Note that some older drives also required a slave-present jumper be set if the drive was configured as a master with a slave drive on the same cable. You'll find more detail on the drive configuration procedures later in this chapter.

4. Slide the drive carefully into a drive bay of the correct size. Most hard drives—except for a few very high-capacity SCSI drives meant for servers and the Quantum Bigfoot series—are 3 1/2" wide and 1" high. If you have no 3 1/2" drive bays left for your hard disk, attach a drive-adapter kit to the sides of the drive to make it wide enough to fit into a 5 1/4" wide drive bay (refer to Figure 14.3). Some case designs require you to attach rails to the side of the hard drive. If so, attach them to the drive using the screws supplied with either the case or the drive. Be sure the screws aren't too long; if you bottom the screws in the drive, you can damage it. Then, slide the drive into the bay in the case until the rails latch into place.

Note

You can find more visual step-by-step instructions for installing a hard drive in Chapter 22, "Building or Upgrading Systems."

5. Attach the data cable connector to the back of the drive, unless you are adding the drive and cable at the same time. In that case, attach the cable to the drive before you slide it into the drive bay and fasten it into place (step 2).
6. Attach the appropriate power connector to the drive. Most hard drives use the larger, or "Molex," four-wire power connector. If necessary, purchase a Y-splitter cable (see Figure 14.4) to create two power connectors from one (many computers have fewer power connectors than drive bays).

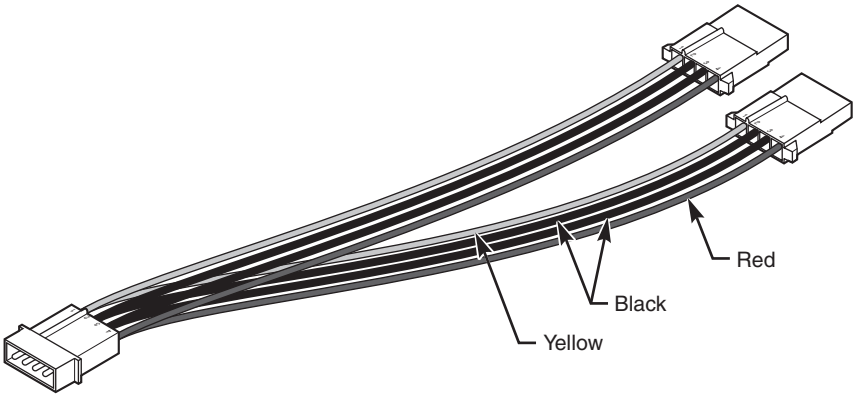

Figure 14.4 Power cord splitter and connector.

7. Turn on the computer and listen for the new hard disk to spin up. Even though today's drives are very quiet compared to early hard disks, you should still hear a faint rattling or clicking as the new hard disk starts to run. If you don't hear anything from the drive, double-check the data and power cables.
8. Restart the computer and access the BIOS setup screens to configure the new hard disk. If your BIOS has an autodetect or auto type setting, I recommend you use it because it will configure the parameters automatically using optimal settings. For ATA hard drives above 528MB (504 megabytes), you also must set logical block address (LBA) translation to access the drive's full capacity. If autodetect was selected, LBA translation should already be set correctly. Many systems have a Peripherals Configuration screen, which also enables you to set transfer speeds for

maximum drive performance, but again these should be configured automatically if you enabled autodetect. If your BIOS can't autodetect your drive, see the documentation that came with the drive for the correct settings. Most drives have the CHS parameters as well as jumper setting information displayed on a sticker attached to the drive, and all modern BIOSes support autodetect, as well. Save the BIOS configuration and exit the BIOS Setup screen to continue. The following section has more information on this step, as it can be complicated.

9. Restart the computer and prepare to run FDISK to prepare the hard drive for formatting and use. Or, you can use drive partitioning software, such as PowerQuest's PartitionMagic, to automatically create and manage disk partitions. Normally, FDISK can be found on the operating system start disk, such as the Windows startup disk. Simply insert the startup disk in the floppy drive, boot from it, and type the `FDISK` command at the `A:` prompt.

◀◀ See "ATA IDE," p. 496, and "The SCSI Interface," p. 537.

System Configuration

After your drive is physically installed, you must provide the computer with basic information about the drive so the system can access and boot from it. How you set and store this information depends on the type of drive and system you have. Standard ATA setup procedures apply for most hard disks except SCSI drives. SCSI drives usually follow a custom setup procedure that varies depending on the host adapter you are using. If you have a SCSI drive, follow the instructions included with the host adapter to configure the drive.

Automatic Drive Detection

For ATA drives, virtually all new BIOS versions in today's PCs have automatic parameter detection (autodetect). The BIOS sends a special Identify Drive command to all the devices connected to the ATA interface during the system startup sequence; the drives are intelligent enough to respond with the correct parameters. The BIOS then automatically enters the parameter information returned by the drive. This procedure eliminates errors or confusion in parameter selection.

Manual Drive Parameters

If you are dealing with a motherboard that does not support autodetect, you must enter the appropriate drive information in the system BIOS manually. The BIOS has a selection of preconfigured drive types, but these are woefully outdated in most cases, providing support only for drives holding a few hundred megabytes or less. In nearly every case, you must select the user-defined drive type and provide values for the following settings:

- Cylinders
- Heads
- Sectors per track

The values you use for these settings should be provided in the documentation for the hard disk drive, but they also might be printed on the drive itself. It's a good idea to check for these settings and write them down because they might not be visible after you've installed the drive. You also should maintain a copy of these settings in case your system BIOS loses its data due to a battery failure. One of the best places to store this information is inside the computer itself. Taping a note with vital settings such as these to the inside of the case can be a lifesaver.

In the event that you are unable to determine the correct settings for your hard drive from either the drive case or the Technical Reference, utility programs are available on the Internet that can query the drive for this information.

Note

The setup parameters for more than 1,000 popular drive models are included in the Technical Reference on the DVD.

Depending on the maker and version of your system BIOS, you might have to configure other settings as well, such as which transfer mode to use and whether the BIOS should use logical block addressing.

◀◀ See "Drive Capacity Limitations," p. 512.

Formatting

Proper setup and formatting are critical to a drive's performance and reliability. This section describes the procedures used to format a hard disk drive correctly. Use these procedures when you install a new drive in a system or immediately after you recover data from a hard disk that has been exhibiting problems.

The three major steps in the formatting process for a hard disk drive subsystem are as follows:

1. Low-level formatting
2. Partitioning
3. High-level formatting

Low-Level Formatting

All new hard disk drives are low-level formatted by the manufacturer, and you do not have to perform another LLF before you install the drive. In fact, under normal circumstances, you should not ever have to perform a low-level format on an ATA or SCSI drive. Most manufacturers no longer recommend that you low-level format any ATA type drive.

This recommendation has been the source of some myths about ATA. Many people say, for example, that you can't perform a low-level format on an ATA drive, and that if you do, you will destroy the drive. This statement is untrue! What can happen with some of the earliest ATA drives is that you might lose the optimal head and cylinder skew factors that were set by the manufacturer for the drive, as well as the map of drive defects. This can have a negative effect on the drive's performance, but you can still reliably use the drive. Note that all drives that internally use a zoned recording (where there is a variable number of sectors per track internally) are immune to any problems due to low-level formatting because the actual sector marks can't be rewritten. This includes pretty much all modern ATA drives made in the last 10 years.

However, sometimes you must perform a low-level format on an ATA or a SCSI drive. The following sections discuss the software you can use to do this.

SCSI Low-Level Format Software

SCSI drives also come preformatted, and unless there is a problem with the drive, you will not have to perform this operation yourself. If you do want to low-level format a SCSI drive, you must use the LLF program provided by the manufacturer of the SCSI host adapter. The designs of these devices vary enough that a register-level program can work only if it is tailored to the individual controller. Fortunately, all SCSI host adapters include low-level format software, either in the host adapter's BIOS or in a separate disk-based program.

The interface to the SCSI drive is through the host adapter. SCSI is a standard, but no true standards exist for what a host adapter is supposed to look like. This means that any formatting or configuration software is specific to a particular host adapter.

Note

Notice that SCSI format and configuration software is keyed to the host adapter and is not specific in any way to the particular SCSI hard disk drive you are using.

ATA Low-Level Format Software

ATA drive manufacturers have defined and standardized extensions to the original WD1002/1003 hard disk controller card to AT-bus (ISA) interface, which is known as the ATA (AT Attachment) interface. The ATA specification provides for vendor-unique commands, which are manufacturer proprietary extensions to the standard. To prevent improper low-level formatting, many of these ATA drives have special codes that must be sent to the drive to unlock the format routines. These codes vary among manufacturers. If possible, you should obtain LLF and defect management software from the drive manufacturer; this software usually is specific to that manufacturer's products and often is model specific. Check the brand and model number of your hard disk to determine the utility program you need.

Most ATA drives are protected from any alteration to the skew factors or defect map erasure because they are always in a translated mode internally. Zoned bit recording drives are always under translation and are fully protected. Most ATA drives have a custom command set that must be used in the format process; the standard format commands defined by the ATA specification usually do not work, especially with intelligent or zoned bit recording ATA drives. Without the proper manufacturer-specific format commands, you can't perform the defect management by the manufacturer-specified method, in which bad sectors often can be spared.

Most manufacturers supply low-level format programs for their drives. Here are a few examples:

- *Seagate.* `ftp://ftp.seagate.com/techsuppt/seagate_utils/sgatfmt4.zip` or `http://www.seagate.com/support/seatools`
- *IBM.* `http://www.storage.ibm.com/hdd/support/download.htm`
- *Maxtor/Quantum.* `http://www.maxtor.com/softwaredownload/default.htm`
- *Western Digital.* `http://www.wdc.com/service/ftp/drives.html` or `http://www.wdc.com/service/ftp/wddiag/wd_diag.exe`

You should try the manufacturer-specific format programs first. They are free, can often work at a lower level, and can handle defects in ways that the more generic ones can't. If formatting software is not available from your drive's manufacturer, I recommend Disk Manager by Ontrack and the Micro-Scope program by Micro 2000. Another excellent, inexpensive, general-purpose PC hardware diagnostic that includes low-level format capability is the IBM Drive Fitness Test (DFT) program. IBM's Drive Fitness Test program works on non-IBM drives as well and performs a detailed and thorough test of your hard drive. I recommend this as one of the best general-purpose drive test programs on the market because it can do a fairly thorough test in nondestructive mode. It performs an LLF (destructive) only on IBM-brand drives. You can download DFT from the IBM site listed previously.

Note

Although Ontrack Disk Manager can be purchased in a "generic" version that works with any manufacturer's hard drives, brand-specific OEM versions are often available free of charge on the utility disks or CD-ROMs shipped with new retail-packaged hard disk drives. You should also check your drive maker's Web site for updated versions of Disk Manager. These OEM versions are designed to check for a particular brand's drive firmware and do not work on any brand other than the one for which they are modified.

Nondestructive Formatters

General-purpose, BIOS-level, nondestructive formatters, such as Calibrate (older Symantec Norton Utilities) and SpinRite (Gibson Research), are not recommended in most situations in which a real LLF is required. These programs have several limitations and problems that decrease their effectiveness; in some cases, they can even cause problems with the way defects are handled on a drive. These programs attempt to perform a track-by-track LLF by using BIOS functions, while backing up and restoring the track data as they go. These programs do not actually perform a complete LLF because they do not even try to low-level format the first track (Cylinder 0, Head 0) due to problems with some controller types that store hidden information on the first track.

These programs also do not perform defect mapping in the way standard LLF programs do, and they even can remove the carefully applied sector header defect marks during a proper LLF. This situation potentially enables data to be stored in sectors that originally were marked defective and might actually void the manufacturer's warranty on some drives. Another problem is that these programs work only on drives that have already been formatted and can format only drives that are formattable through BIOS functions.

Note

SpinRite is useful for recovering data found on drives with read errors because of its thorough method of repeatedly rereading the errors and analyzing the results to reconstruct the missing data.

A true LLF program bypasses the system BIOS and sends commands directly to the disk controller hardware. For this reason, many LLF programs are specific to the disk controller hardware for which they are designed. Having a single format program that will run on all types of controllers is virtually impossible. Many hard drives have been incorrectly diagnosed as being defective because the wrong format program was used and the program did not operate properly.

Drive Partitioning

Partitioning a hard disk is the act of defining areas of the disk for an operating system to use as a volume.

When you partition a disk, the partitioning software writes a master partition boot sector at Cylinder 0, Head 0, Sector 1—the first sector on the hard disk. This sector contains data that describes the partitions by their starting and ending cylinder, head, and sector locations. The partition table also indicates to the ROM BIOS which of the partitions is bootable and, therefore, where to look for an operating system to load.

▶▶ See "File Systems and Data Recovery," p. 1339.

The FDISK program is the accepted standard for partitioning hard disk drives for use with all operating systems up through Windows Me. Windows 2000 and XP use a similar program called DISKPART. All versions of Windows starting with Windows 95 can also partition and format the drive using the SETUP program for installing the OS. These programs are included with your operating system, and although they might have the same name and basic functions with any OS, you should typically use the tools that specifically came with your OS. Partitioning prepares the boot sector of the disk in such a way that the FORMAT program or the Windows SETUP format utility can operate correctly. Partitioning also enables various operating systems to coexist on a single hard disk. No matter which operating system you use, it should come with an FDISK, DISKPART, or SETUP program that can be used to partition the drive.

Note

Because FDISK, DISKPART, and SETUP depend on BIOS information about the hard disk to determine the size and drive geometry of the hard disk, having correct BIOS settings saved in the BIOS Setup is vital to the correct operation of these programs. If a 100GB hard drive is defined in the BIOS as a 100MB hard drive, for example, all these programs will see is 100MB.

With any version of Windows, as with MS-DOS, FDISK enables you to create two types of disk partitions: primary and extended. A primary partition can be bootable but an extended partition can't. If you have only a single hard disk in your system, at least part of the drive must be prepared as a primary partition if you want to start your computer from the hard disk (and who doesn't?). A primary partition is seen as a single volume or drive letter (C: on one-drive systems), whereas an extended partition acts as a sort of logical container for additional volumes (drive letters D: and beyond). A single extended partition can contain a single volume (also referred to by FDISK as a *logical DOS drive*) or several volumes (logical DOS drives) of various sizes.

Don't get hung up on the fact that FDISK calls partitions "DOS" partitions or "DOS" drives. This is true even though the operating system you are installing is Windows 95, 98, Me, NT, 2000, XP, Linux, and so on.

Depending on the version of Windows in use (and with any version of MS-DOS), you might need to subdivide a hard drive through the use of FDISK. The original release of Windows 95 and all MS-DOS versions support a file system known as FAT16, which allows no more than 65,536 files per drive and a single drive letter or volume size of no more than 2.1GB. Thus, a 10GB hard disk prepared with MS-DOS or the original Windows 95 (or 95A) must have a minimum of five drive letters and could have more (see Figure 14.5).

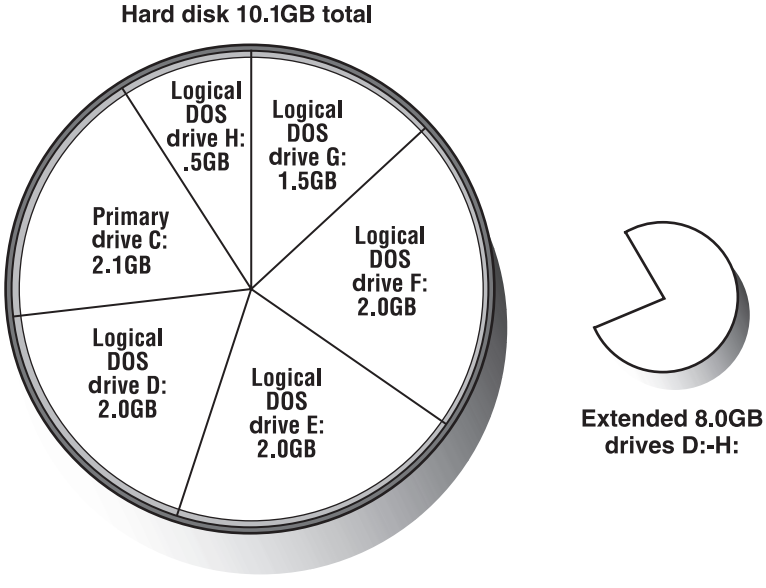

Figure 14.5 Adding a hard drive above 2.1GB in size to an MS-DOS or original Windows 95A computer forces the user to create multiple drive letters to use the entire drive capacity. The logical DOS drives are referenced like any other drive, although they are portions of a single physical hard disk.

▶▶ See "File Allocation Table," p. 1340.

Another reason for subdividing a single drive into multiple volumes is increased data security. For example, PowerQuest (the creator of PartitionMagic) suggests a three-volume partitioning scheme that looks like this:

C: for the operating system and utilities

D: for applications

E: and above for data

In this example, primary and extended partitions would be assigned as shown here:

C: the primary partition

D: and E: in the extended partition as logical DOS drives (volumes)

If a catastrophic failure to the disk structure wipes out C: or D:, drive E:—which contains the data—is usually still intact. This method also makes backing up the data easier; just set the backup program to back up all of E:, or all the changed files on E:.

Large Hard Disk Support

If you use the Windows 95B or above (Win95 OSR 2.x), Windows 98, Windows Me, or Windows 2000 versions of FDISK with a hard drive greater than 512MB, FDISK offers to enable large disk support.

Choosing to enable large disk support provides several benefits:

- *You can use a large hard disk (greater than 2.1GB) as a single drive letter.* In fact, your drive can be as large as 2TB and still be identified by a single drive letter. This is because of the FAT32 file system, which allows for many more files per drive than FAT16.

▶▶ See "FAT32," p. 1358.

- *Because of the more efficient storage methods of FAT-32, your files will use less hard disk space overall.*

However, keep in mind that all disk operations must be performed through an operating system with FAT32 support (Windows 95B or later, Windows 98, Windows Me, or Windows 2000). If you have old MS-DOS games or applications that are bootable, you won't be able to access a FAT32 volume unless you replace the DOS version on the disk with the DOS included on Win95B or Windows 98. This normally can be done by using the `SYS A:` command from the `\Windows\Command` folder. Another option is to use the Windows Startup menu in Win95B or Win98 (press F8 as Windows starts to load) and select Command Prompt to get to a FAT32-capable DOS. On the other hand, you can select Start, Shutdown, Restart the Computer in MS-DOS Mode from the Windows desktop.

A drive prepared with the large hard disk support (FAT32) option enabled can still be partitioned into primary and secondary partitions with FDISK, as with FAT16 for the data-security reasons listed earlier.

Another type of file system is NTFS, which is supported by only Windows NT and Windows 2000. This is a high-performance file system with additional security and networking features. NTFS was revised to NTFS5 in Windows NT 4.0 with Service Pack 4 and later, as well as Windows 2000. It is discussed in more detail in Chapter 24, "File Systems and Data Recovery." Note that Windows 9x can't read NTFS partitions, and Windows NT can't read FAT32 partitions. Windows 2000, however, can handle both FAT32 and NTFS.

Assigning Drive Letters with FDISK

FDISK can be used in many ways, depending on the number of hard drives you have in your system and the number of drive letters you want to create.

With a single drive, creating a primary partition (C:) and an extended partition with two logical DOS drives within it results in the following drive letters:

Partition Type	Drive Letter(s)
Primary	C:
Extended	D: and E:

Most people think that a second physical drive added to this system should have drive letters that follow the E: drive.

However, you must understand how drive letters are allocated by the system to know how to use FDISK correctly in this situation. Table 14.1 shows how FDISK assigns drive letters by drive and partition type.

Table 14.1 Drive Letter Allocations by Drive and Partition Type

Drive	Partition	Order	Drive Letter
1st	Primary	1st	C:
1st	Extended	3rd	E:
2nd	Primary	2nd	D:
2nd	Extended	4th	F:

How does this affect you when you add another hard drive? If you prepare the second hard drive with a primary partition and your first hard drive has an extended partition on it, the second hard drive takes the primary partition's D: drive letter. This moves all the drive letters in the first hard drive's extended partition up one drive letter.

In the first example, a drive is listed with C: (primary partition), D:, and E: (extended partition volumes) as the drive letters (D: and E: were in the extended partition). Table 14.2 indicates what happens if a second drive is added with a primary partition and an extended partition with two volumes (same setup as the first drive).

Table 14.2 Drive Letter Changes Caused by Addition of Second Drive with Primary Partition

Drive	Partition Type	Order	Original Drive Letters (First Drive Only)	New Drive Letters After Adding Second Drive
1st	Primary	1st	C:	C:
1st	Extended	3rd	D:, E:	E:, F:
2nd	Primary	2nd		D:
2nd	Extended	4th		G:, H:

After adding the second drive, the original drive letters D: and E: have now become E: and F:. The primary partition on the new drive has become D:, and the extended partition volumes on the second

drive are G: and H:. Confused? Well, you better not be or you'll find yourself deleting or copying data to or from the wrong drive.

This principle extends to third and fourth physical drives as well: The primary partitions on each drive get their drive letters first, followed by logical DOS drives in the extended partitions.

One way to effect this is to partition additional drives with only extended partitions—in other words, do not create primary partitions on them. This enables the new drive's partitions to be seen only as additional letters, and the letters used by the first drive's partitions to remain unchanged.

If you're *adding* a drive to your system, you should now understand why preparing that second, third, or fourth drive with a primary partition is a bad idea. If you're installing an additional hard drive (not a replacement), remember that it can't be a bootable drive. And if it can't be bootable, there's no reason to make it a primary partition. FDISK allows you to create an extended partition using 100% of the space on any drive. Table 14.3 shows the same example used in Table 14.2 with the second drive installed as an extended partition.

Table 14.3 Drive Letter Allocations After Addition of Second Drive with Extended Partition Only

Drive	Partition Type	Order	Original Drive Letters (First Drive Only)	New Drive Letters After Adding Second Drive
1st	Primary	1st	C:	C:
1st	Extended	3rd	D:, E:	D:, E:
2nd	Primary	2nd	—	—
2nd	Extended	4th		F:

When a new drive is added with only extended partition volumes, you can see that the original drive letters remain undisturbed. This arrangement is much easier to understand, and it prevents accidents with data because of drive letters changing. This operating system behavior also explains why some of the first computers with ATA-based (ATAPI) Iomega Zip drives had the Zip drive as D:, with a single hard disk identified as C: and E:. The Zip drive was treated as the second hard drive with a primary partition. Subsequently, Iomega changed the Zip drive format and driver so that the Zip disk is recognized as an extended partition at the end of the drive letter chain.

Running FDISK

When you run newer versions of FDISK, the first thing that happens is you are prompted with the following:

```
Do you wish to enable large disk support (Y/N).....? [Y]
```

If you answer Yes to this question, FDISK creates FAT32 volumes for all volumes created that are larger than 512MB. Answering No to this question forces FDISK to create only FAT16 volumes, which are limited to a 2GB maximum size and waste more space on the disk due to larger cluster sizes.

Normally, in a modern system you would answer Yes, allowing the use of FAT32. After answering the question, FDISK shows a menu similar to the following:

```
Current fixed disk drive: 1

    Choose one of the following:

    1. Create DOS partition or Logical DOS Drive
    2. Set active partition
    3. Delete partition or Logical DOS Drive
    4. Display partition information
    5. Change current fixed disk drive

    Enter choice: [1]
```

Option 5 is shown only if FDISK detects more than one drive on your system (if more than one is entered via your BIOS Setup). In that case, FDISK defaults to the first drive, and via option 5 you can cause FDISK to work with any of the other hard disks on the system.

To create partitions, you select option 1. If the drive is already partitioned, however, you can use option 4 to display the current layout of the drive.

After selecting option 1, the menu changes to enable you to create primary or extended partitions on a drive as follows:

```
Create DOS Partition or Logical DOS Drive

    Current fixed disk drive: 1

    Choose one of the following:

    1. Create Primary DOS Partition
    2. Create Extended DOS Partition
    3. Create Logical DOS Drive(s) in the Extended DOS Partition

    Enter choice: [1]
```

The rules require you to create a primary partition first on the boot drive, but on a secondary or non-boot drive, you can create just an extended partition if you choose. So, if you are partitioning the first drive in a system and it will be bootable, you would choose option 1.

At this point, you are prompted to decide whether you want to use the maximum available size for a Primary DOS Partition. If you say Yes and you're using FAT32, the primary partition uses the entire drive. Conversely, if you say Yes and you did not enable large drive support (meaning you are using FAT16), the partition uses the entire drive or 2GB, whichever is smaller.

If you decide to create a primary partition that is not the full drive, you should go back through the menus and create an extended partition using the rest of the drive, and then further divide it into logical drives. Normally, I recommend making the primary partition the full size of the drive, keeping all of the drive as one letter. But there are various reasons you might want to split the drive into multiple partitions, such as for different operating systems, different file systems, applications, and so on.

After all the partitions are created, the final operation is to make one of them active (bootable), which is option 2 from the main FDISK menu. Typically, the only one that can be active is the primary partition. After that is done, all FDISK operations are complete, and you can exit the program.

When exiting FDISK after making partition changes, the system must be rebooted before these changes will be recognized. After rebooting, you must then high-level format each of the volumes with the operating system `FORMAT` command, which then allows the operating system to store files on them.

The C: volume usually must be formatted with the system files, although when you install Windows via the Windows Setup command, it detects whether the system files are present and offers to install them for you.

Drive Partitioning with Aftermarket Utilities

Alternative partitioning programs such as PartitionMagic by PowerQuest and Partition Commander by V-Communications enable you to take an existing hard drive and perform the following changes to it without loss of data:

- Create, resize, split, move, and merge partitions on the fly without losing data.
- Convert between file systems without losing data—conversions include FAT to FAT32 and NTFS; FAT32 to FAT; NTFS to FAT and FAT32; primary to logical and vice versa; and FAT32 to NTFS under Windows 2000 Professional. It also includes support for ext2 and Linux SWAP file systems.
- Move applications between partitions and automatically update the drive-letter references after partitioning with their DriveMapper utility.
- Undelete FAT, FAT32, Linux ext2, and NTFS partitions that have been deleted. You can restore partitions that have been deleted on disk as long as the space has not been reallocated or written over.
- Copy or move a partition to another partition or drive.

Note

I still recommend FDISK, DISKPART, or SETUP be used for initial partitioning and setup of any drive, but these aftermarket utilities can be very useful for reconfiguring a system that is already partitioned.

Although the program recommends a full backup before starting, I've used these utilities many times to turn a single "big drive" into two or more drive letters in less than 10 minutes. Performing the same task with backup software and FDISK/FORMAT can take several hours.

High-Level (Operating System) Formatting

The final step in the installation of a hard disk drive is the high-level format. Similar to the partitioning process, the high-level format is specific to the file system you've chosen to use on the drive. On Windows 9x and DOS systems, the primary function of the high-level format is to create a FAT and a directory system on the disk so the operating system can manage files. You must run FDISK before formatting a drive. Each drive letter created by FDISK must be formatted before it can be used for data storage.

Usually, you perform the high-level format with the FORMAT.COM program or the formatting utility in Windows 9x Explorer. FORMAT.COM uses the following syntax:

```
FORMAT C: /S /V
```

This command high-level formats drive C:, writes the hidden operating system files in the first part of the partition, and prompts for the entry of a volume label to be stored on the disk at the completion of the process.

The FAT high-level format program performs the following functions and procedures:

1. Scans the disk (read-only) for tracks and sectors marked as bad during the LLF, and notes these tracks as being unreadable.

2. Returns the drive heads to the first cylinder of the partition, and at that cylinder (Head 1, Sector 1) writes a DOS volume boot sector.
3. Writes a FAT at Head 1, Sector 2. Immediately after this FAT, it writes a second copy of the FAT. These FATs are essentially blank except for bad-cluster marks noting areas of the disk that were found to be unreadable during the marked-defect scan.
4. Writes a blank root directory.
5. If the `/S` parameter is specified, copies the system files, `IO.SYS` and `MSDOS.SYS` (or `IBMBIO.COM` and `IBMDOS.COM`, depending on which DOS you run), and `COMMAND.COM` to the disk (in that order).
6. If the `/V` parameter is specified, prompts the user for a volume label, which is written as the fourth file entry in the root directory.

Now, the operating system can use the disk for storing and retrieving files, and the disk is a bootable disk.

During the first phase of the high-level format, the program performs a marked defect scan. Defects marked by the LLF operation show up during this scan as being unreadable tracks or sectors. When the high-level format encounters one of these areas, it automatically performs up to five retries to read these tracks or sectors. If the unreadable area was marked by the LLF, the read fails on all attempts.

After five retries, the DOS FORMAT program gives up on this track or sector and moves to the next one. If an area remains unreadable after the initial read and five retries, it is marked in the FAT as a bad cluster.

Note

Because the high-level format doesn't overwrite data areas beyond the root directory of the hard disk, using programs such as Norton Utilities to unformat the hard disk that contains data from previous operations is possible, provided no programs or data has been copied to the drive after high-level formatting. Unformatting can be performed because the data from the drive's previous use is still present.

If you create an extended partition, the logical DOS drive letters found there need a simpler `FORMAT` command because system files aren't necessary—for example, `FORMAT D:/V` for drive D:, `FORMAT E:/V` for drive E:, and so on.

FDISK and FORMAT Limitations

The biggest problem with FDISK is that it is destructive. If you change your mind about disk structure, you must back up your system and start over again. That alone is cause for using FDISK with care, but here are other limitations you should keep in mind:

- FDISK doesn't provide any help with issues of drive letter changes.
- FDISK requires FORMAT before the drive is ready for use.
- FORMAT must check the entire drive before making it ready for use. Its error management is rudimentary and can waste a lot of disk space with older drives that have disk errors.
- FDISK and FORMAT are designed for a single operating system environment, with no provision for multiboot options (Windows 9x and NT or Windows 9x and Linux, for example).
- FDISK and FORMAT offer no procedure for migrating data to a new drive, and the `XCOPY` command is tricky to use.

- FDISK and FORMAT might cause conflicts with existing CD-ROM drives, which often use the next available drive letter after the existing hard drive.

For these reasons, many drive vendors offer some type of automatic disk installation software with their hard drives. These routines can make the task of disk migration a fast, easy, and reliable operation.

Typical features of automatic disk installation programs include the following:

- *Replacement for FDISK and FORMAT.* A single program performs both functions more quickly than FDISK and FORMAT separately.
- *Database of drive jumpers for major brands and models.*
- *Drive copy function.* Copies contents of old MS-DOS or Windows 9x drive to the new drive, retaining long filenames, file attributes, and so on.
- *CD-ROM drive letter relocation utility.* Moves CD-ROM to new drive letter (to make room for new hard drive letters) and resets Windows Registry and INI file references to the new drive letter so CD-ROM software works without reinstallation.
- *Menu-driven or wizard-driven process for installing new hard drive.*
- *Optional override of BIOS limitations for installation of large hard drives (>504MB, 2.1GB, 8.4GB, and so on).*

The two major vendors in the automated disk-utility business are Ontrack Data International, Inc., and StorageSoft. These companies sell their disk-installation products to OEM hard drive vendors for use with particular brands of drives. They also sell to the public "generic" versions that can be purchased for use with any brand or model of hard disk. Table 14.4 provides a basic overview of the most popular disk-installation programs.

Table 14.4 Overview of Automatic Disk-Installation Programs

Vendor	Software	Current Version	OEM	Retail
	Disk Manager 2000[1]	4.xx	Yes	Yes
StorageSoft[2]	EZ Drive	9x	Yes	Yes
	DrivePro	3.x	No	Yes
Seagate[3]	DiscWizard	2002	Yes	No
Maxtor[4]	MaxBlast Plus II	1.x	Yes	No

1. Disk Manager 2000 (v4.xx) has replaced Disk Manager DiskGo!

2. Phoenix Technologies acquired StorageSoft in 2002. Its DrivePro software, which it hasn't updated since December 1997, might not be compatible with newer hardware.

3. Seagate's DiscWizard was co-developed with Ontrack and contains Ontrack Disk Manager v9.x.

4. Maxtor's MaxBlast! Software v9.x is a customized version of EZ-Drive. Versions 7.x and 8.x of MaxBlast! are customized versions of Ontrack Disk Manager.

Disk Manager and EZ-Drive are DOS-based utility programs, whereas DiscWizard and Disk Manager DiskGo! offer a Windows-like interface. Seagate's DiscWizard actually analyzes the system, asks the user questions about the intended installation, and prepares a customized procedure based on the user's responses.

OEM versions of disk-installation programs are available from the drive makers' Web sites; retail versions usable with any combination of drives can be purchased from retail stores or at the vendors' online stores.

Replacing an Existing Drive

Previous sections discussed installing a single hard drive or adding a new hard drive to a system. Although formatting and partitioning a new hard disk can be challenging, replacing an existing drive and moving your programs and files to it can be a lot more challenging.

Drive Migration for MS-DOS Users

When MS-DOS 6.x was dominant, many users used this straightforward method to transfer the contents of their old hard drive to their new hard drive:

1. The user creates a bootable disk containing FDISK, FORMAT, and XCOPY.
2. The new hard drive is prepared with a primary partition (and possibly an extended partition, depending on the user's desires).
3. The new hard drive is formatted with system files, although the operating system identifies it as D:.
4. The `XCOPY` command is used to transfer all non-hidden files from C:\ (the old hard drive) to D:\, thus:

   ```
   XCOPY C:\ D:\/S/E
   ```

   The `XCOPY` command also is used as necessary to transfer files from any remaining drive letters on the old hard drive to the corresponding drive letters on the new drive.

Because the only hidden files such a system would have were probably the operating system boot files (already installed) and the Windows 3.1 permanent swap file (which could be re-created after restarting Windows), this "free" data transfer routine worked well for many people.

After the original drive was removed from the system, the new drive would be jumpered as master and assigned C:. The user then would need to run FDISK from a floppy and set the primary partition on the new C: drive as Active. Then, the user would exit FDISK and the drive would boot.

Drive Migration for Windows 9x/Me Users

Windows 9x/Me have complicated the once-simple act of data transfer to a new system by their frequent use of hidden files and folders (such as `\Windows\Inf`, where Windows 9x hardware drivers are stored). The extensive use of hidden files was a major reason for a greatly enhanced version of XCOPY being included in Windows 9x/Me.

Note

XCOPY32 is automatically used in place of XCOPY when XCOPY is started within a command prompt session under Windows.

XCOPY32 for Windows 9x Data Transfer

Compared to "classic" XCOPY, XCOPY32 can copy hidden files; can preserve file attributes such as system, hidden, read-only, and archive; can automatically create folders; and is compatible with long filenames. Thus, using it to duplicate an existing drive is possible, but with these cautions:

- The `XCOPY32` command is much more complex.
- Errors might occur during the copy process because of Windows' use of temporary files during normal operation, but XCOPY32 can be forced to continue.

This command line calls XCOPY32 and transfers all files and folders with their original attributes intact from the original drive (C:) to the new drive (D:). This command, however, must be run from an MS-DOS prompt window (and not MS-DOS Mode) under Windows 9x/Me, as follows:

```
xcopy32 c:\. d:\ /e/c/h/r/k
```

The command switches are explained here:

- `/e`. Copies folders, even if empty; also copies all folders beneath the starting folder.
- `/c`. Continues to copy after errors. The Windows swap file can't be copied due to being in use.
- `/h`. Copies hidden and system files.
- `/r`. Overwrites read-only files.
- `/k`. Preserves file attributes.

Repeat the command with appropriate drive-letter changes for any additional drive letters on your old drive.

After the original drive is removed from the system, the new drive must be jumpered as master (or single), and the operating system assigns it C:. You next need to run FDISK from a floppy and set the primary partition on the new C: drive as Active. Then, exit FDISK, and the drive will boot.

Note that although the XCOPY method has worked for me, some people have problems with it. A much more automated and easy approach to cloning drives is to use commercial software designed for that purpose, such as Drive Copy by PowerQuest or Norton Ghost by Symantec.

Even though many users have prepared new hard drives for use with nothing but FDISK and FORMAT, today's more complex systems are presenting increasingly good reasons for looking at alternatives.

Interfacing to Disk Drives

DOS uses a combination of disk management components to make files accessible. These components differ slightly between floppies and hard disks and among disks of varying sizes. They determine how a disk appears to DOS and applications. Each component used to describe the disk system fits as a layer into the complete system. Each layer communicates with the layer above and below it. When all the components work together, an application can access the disk to find and store data.

Four primary interface layers exist between an application program running on a system and the disk drives attached to the system. They consist of software routines that can perform various functions, usually to communicate with the adjacent layers. These layers are as follows:

- DOS Interrupt 21h (Int 21h) routines
- DOS Interrupt 25/26h (Int 25/26h) routines
- ROM BIOS Disk Interrupt 13h (Int 13h) routines
- Disk controller I/O port commands

Each layer accepts various commands, performs different functions, and generates results. These interfaces are available for both floppy disk drives and hard disks, although the floppy disk and hard disk Int 13h routines differ widely. The floppy disk controllers and hard disk controllers are very different as well, but all the layers perform the same functions for both floppy disks and hard disks.

Interrupt 21h

The DOS Int 21h routines exist at the highest level and provide the most functionality with the least amount of work. For example, if an application program needs to create a subdirectory on a disk, it can call Int 21h, Function 39h. This function performs all the operations necessary to create the subdirectory, including updating the appropriate directory and FAT sectors. The only information this function needs is the name of the subdirectory to create. DOS Int 21h would do much more work by using one of the lower-level access methods to create a subdirectory. Most applications access the disk through this level of interface.

Interrupt 25h and 26h

The DOS Int 25h and Int 26h routines provide much lower-level access to the disk than the Int 21h routines. Int 25h reads only specified sectors from a disk, and Int 26h writes only specified sectors to a disk. If you were to write a program that used these functions to create a subdirectory on a disk, the amount of work would be much greater than that required by the Int 21h method. For example, your program would have to perform all these tasks:

- Calculate exactly which directory and FAT sectors need to be updated.
- Use Int 25h to read these sectors.
- Modify the sectors appropriately to add the new subdirectory information.
- Use Int 26h to write the sectors back to the disk.

The number of steps is even greater when you factor in the difficulty in determining exactly which sectors must be modified. According to Int 25/26h, the entire DOS-addressable area of the disk consists of sectors numbered sequentially from 0. A program designed to access the disk using Int 25h and Int 26h must know the correct disk locations by sector number. A program designed this way might have to be modified to handle disks with different numbers of sectors or different directory and FAT sizes and locations. Because of all the overhead required to get the job done, most programmers do not choose to access the disk in this manner and instead use the higher-level Int 21h, which does all the work automatically.

Typically, only disk- and sector-editing programs access disk drives at the Int 25h and Int 26h level. Programs that work at this level of access can edit only areas of a disk that have been defined to DOS as a logical volume (drive letter). For example, the DOS DEBUG program can read sectors from and write sectors to disks with this level of access.

Interrupt 13h

The next lower level of communications with drives, the ROM BIOS Int 13h routines, usually are found in ROM chips on the motherboard or on an adapter card in an expansion slot. However, an Int 13h handler also can be implemented by using a device driver loaded at boot time. Because DOS requires Int 13h access to boot from a drive (and a device driver can't be loaded until after bootup), only drives with ROM BIOS–based Int 13h support can be bootable. Int 13h routines communicate directly with the controller using the I/O ports on the controller.

Note

The DVD accompanying this book contains a list of functions available at the Interrupt 13h BIOS interface, as well as the error codes that might be returned by the BIOS INT 13h routines. See the Technical Reference section of the DVD.

Few high-powered disk utility programs, other than some basic disk-formatting applications, can talk to the disk at the Int 13h level. The DOS FDISK program communicates at the Int 13h level, as does the Norton Utilities' DISKEDIT program when it is in its absolute sector mode; these are some of the few disk-repair utilities that can do so. These programs are important because you can use them for the worst data recovery situations in which the partition tables have been corrupted. Because the partition tables, and any non-DOS partitions, exist outside the area of a disk that is defined by DOS, only programs that work at the Int 13h level can access them. Most utility programs for data recovery work at only the DOS Int 25/26h level, which makes them useless for accessing areas of a disk outside DOS's domain.

Disk Controller I/O Port Commands

At the lowest interface level, programs communicate directly with the disk controller in the controller's own specific native language. To do this, a program must send controller commands through the I/O ports to which the controller responds.

◀◀ See "IDE Origins," p. 494.

Most applications work through the Int 21h interface. This interface passes commands to the ROM BIOS as Int 13h commands; the ROM BIOS then converts these commands into direct controller commands. The controller executes the commands and returns the results through the layers until the desired information reaches the application. This process enables developers to write applications without worrying about such low-level system details, leaving them instead up to DOS and the ROM BIOS. This also enables applications to run on widely varying types of hardware—as long as the correct ROM BIOS and DOS support is in place.

Any software can bypass any level of interface and communicate with the level below it, but doing so requires much more work. The lowest level of interface available is direct communication with the controller using I/O port commands. Each type of controller has different I/O port locations. With different controllers also come differences among the commands presented at the ports. Only the controller can talk directly to the disk drive.

If not for the ROM BIOS Int 13h interface, a unique DOS would have to be written for each available type of hard and floppy disk drive. Instead, DOS communicates with the ROM BIOS using standard Int 13h function calls translated by the Int 13h interface into commands for the specific hardware. Because of the standard ROM BIOS interface, DOS is relatively independent from the disk hardware and can support many types of drives and controllers.

Hard Disk Drive Troubleshooting and Repair

If a hard drive has a mechanical problem inside the sealed head disk assembly (HDA), repairing the drive is usually unfeasible. It might be doable, but purchasing a new drive will be far less expensive. If the failure is in the logic board, that board can be replaced with one from a donor drive. Typically, this is done only for the purposes of reading the information on the failed drive because you must purchase a complete second drive to cannibalize for the logic board. The drive manufacturers usually don't sell spare parts for their drives anymore.

Most hard disk drive problems are not mechanical hardware problems; instead, they are "soft" problems that can be solved by a new LLF and defect-mapping session. Soft problems are characterized by a drive that sounds normal but produces various read and write errors.

Hard problems are mechanical, such as when the drive sounds as though it contains loose marbles. Constant scraping and grinding noises from the drive, with no reading or writing capability, also

qualify as hard errors. In these cases, an LLF is unlikely to put the drive back into service. If a hardware problem is indicated, first replace the logic-board assembly. You can make this repair yourself and, if successful, you can recover the data from the drive.

If replacing the logic assembly does not solve the problem, contact the manufacturer or a specialized repair shop that has clean-room facilities for hard disk repair. (See the Vendor's List on the DVD for a list of drive manufacturers and companies that specialize in hard disk drive repair.) However, because of the costs, simply purchasing a new drive is probably more economical.

Testing a Drive

When accessing a drive, determining whether the drive has been partitioned and formatted properly is easy. A simple test can tell you whether a stored drive is in its "raw" condition or has been partitioned and formatted properly. These tests work best if you have a boot disk available and if the spare hard drive is the only hard drive attached.

First, attach the drive to your system. If you can attach power and data cables to it, you need not install it into a drive bay unless you are planning to use it immediately. If the drive will be run loose, I recommend placing it on a nonconductive foam pad or other soft surface. This insulates the drive from potential shocks and other hazards. After detecting the drive in the BIOS and saving the changes, start your operating system from the boot disk.

Then, from the `A:` prompt, enter the following command:

```
DIR C:
```

This produces one of the following responses:

- *Invalid drive specification*. This indicates the drive does not have a valid partition (created by FDISK) or that the existing Master Boot Sector or partition tables have been damaged. No matter what, the drive must be partitioned and FORMATted before use. You also get this warning on a FAT32 or NTFS partitioned drive if you use a Windows 95 (original version) or MS-DOS boot disk when checking. Use a Windows 95B, Windows 98/Me, or Windows 2000 boot disk to avoid this false message from FAT32 partitions. Or, use a Windows NT or Windows 2000 boot disk to detect NTFS partitions.
- *Invalid media type*. This drive has been partitioned but not FORMATted, or the format has been corrupted. You should use FDISK's #4 option to examine the drive's existing partitions and either delete them and create new ones or keep the existing partitions and run FORMAT on each drive letter.
- *Directory of C:*. The contents of the C: drive are listed, indicating the drive was stored with a valid FDISK and FORMAT structure and data.

Installing an Optical Drive

Installation of a CD-ROM, CD-R, CD-RW, or DVD-ROM drive can be as difficult or as easy as you make it. If you plan ahead, the installation should go smoothly.

This section walks you through the installation of a typical internal (SCSI or ATA) and external (SCSI only) optical drive, with tips that often aren't included in the manufacturers' installation manuals. After you install the hardware, your job might be finished if you are running Windows 9x and using a Plug and Play drive, or you might have to manually load the software necessary to access the drive.

Note

CD-ROM and DVD-ROM drives use the same ATA and SCSI system interfaces and can be installed using the same basic procedures. Some DVD-ROM drives come with an MPEG-2 decoder board or MPEG decoder software that enables you to view DVD movies and video on your PC. If a board is included, it usually installs in a PCI bus slot like any other expansion card and performs the video decoding process that would otherwise fall to the system processor. Software decoding does not require a board and instead uses your processor to do the decoding work. Software decoding normally requires a fast processor (see the software manufacturer's recommendations for how fast); otherwise, the video appears jumpy, jerky, or unsynchronized with the sound. Premium DVD setups almost always include hardware decoding for this reason.

Note that a separate analog or digital audio connection typically exists between the drive and the sound card as well, used primarily for playing audio CDs.

Avoiding Conflict: Get Your Cards in Order

Regardless of the type of installation—internal or external drive—you must have a functioning ATA or SCSI host adapter before the drive can function. In most cases, you will be connecting the optical drive to an existing ATA or SCSI adapter. If so, the adapter should already be configured not to conflict with other devices in your system. All you have to do is connect the drive with the appropriate cable and proceed from there.

Most computers today have an ATA adapter integrated into the motherboard. However, if you are adding SCSI to your system for the first time, you must install a SCSI host adapter into an expansion slot and ensure it is configured to use the appropriate hardware resources, such as the following:

- IRQ
- DMA channel
- I/O port address

As always, Windows 9x/Me/2000 and PnP hardware can completely automate this process; however, if you're using another operating system, you might have to configure the adapter manually.

Drive Configuration

Configuration of your new optical drive is paramount to its proper functioning. Examine your new drive and locate any jumpers (see Figure 14.6). For an ATA drive, here are the typical ways to jumper the drive:

- As the primary (master) drive on the secondary ATA connection
- As the secondary (slave) drive to a current hard disk drive
- Using Cable Select (CS), where the cable connector determines which drive is master or slave automatically

If the drive is to be the only device on your secondary ATA interface, the factory settings are usually correct. Consult the manual to make sure this is so.

When you use the CD-ROM or DVD-ROM as a secondary drive—that is, the second drive on the same ribbon cable with another device—be sure it is jumpered as the slave drive, and configure the other device so it is the master drive (see Figure 14.7). In most cases, the drive shows up as the next logical drive, or the D: drive.

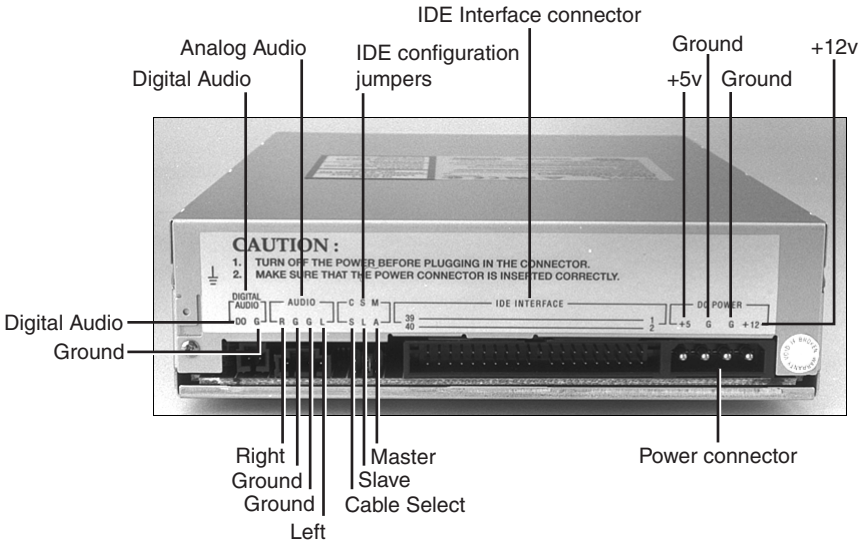

Figure 14.6 The rear connection interfaces of a typical ATA internal CD-ROM drive.

Caution

Whenever possible, you should not connect a CD-ROM or DVD-ROM drive to the same channel as a hard disk drive because devices on the same channel can't simultaneously read or write data. If your computer has the two ATA channels standard in systems today, you should connect the optical drive to the secondary channel, even if you have only one hard disk drive on the primary.

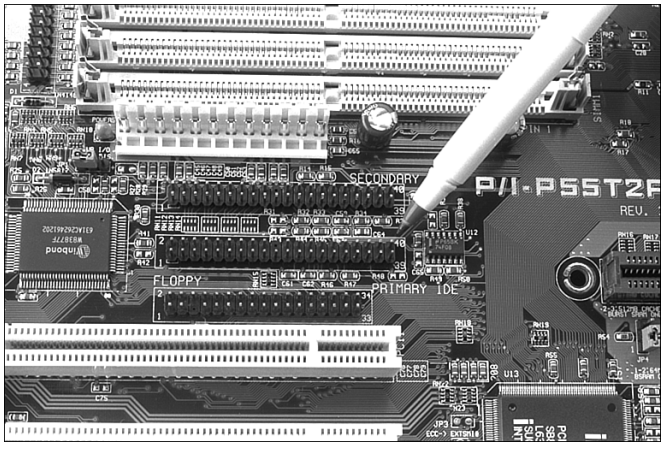

Figure 14.7 An embedded ATA interface with primary and secondary ATA connections (the pen is pointing to the primary ATA connector).

◀◀ These procedures are covered in "The IDE Interface," p. 491, and "The SCSI Interface," p. 537.

Depending on how you look at it, SCSI drives can be a bit easier to configure because you need only to select the proper SCSI ID for the drive. By convention, the boot disk (the C: drive) in a SCSI system is set as ID0, and the host adapter has an ID of 7. You are free to choose any ID in between that is not being used by another device. Most SCSI devices use some type of rotating or pushbutton selector to cycle between the SCSI IDs, but some might use jumpers.

SCSI devices are cabled together in a bus configuration. If your new SCSI drive falls at the end of the SCSI bus, you also must terminate the drive. Note that the SCSI bus refers to the physical arrangement of the devices, and not the SCSI IDs selected for each one.

External (SCSI) Drive Hookup

Unpack the drive carefully. With the purchase of an external drive, you should receive the following items:

- CD-ROM or DVD-ROM drive
- SCSI adapter cable

With the exception of the SCSI host adapter, this is the bare minimum you need to get the drive up and running. You'll probably also find a CD caddy, documentation for the drive, driver software, a SCSI terminator plug, and possibly a sampling of CDs to get you started. SCSI drives almost never come with the SCSI host adapter necessary to connect them to the system. Because SCSI is designed to support up to seven devices on the same system (or up to fifteen devices for Ultra2 SCSI), including a host adapter with every peripheral is impractical. Although a few computers have SCSI interfaces integrated into the motherboard, in most cases you have to purchase a SCSI adapter as a separate expansion card.

To begin the installation, take a look at your work area and the SCSI cable that came with the drive. Where will the drive find a new home? You're limited by the length of the cable. Find a spot for the drive, and insert the power cable into the back of the unit. Be sure you have an outlet or, preferably, a free socket in a surge-suppressing power strip to plug in the new drive.

SCSI devices generally use one of two cable types. Some older drives use a 50-pin Centronics cable, referred to as an A-cable. Most drives today, though, use a 68-pin cable called a P-cable. Plug one end of the supplied cable into the connector socket of the drive and one into the SCSI connector on the adapter card. Most external drives have two connectors on the back—either connector can be hooked to the PC (see Figure 14.8). You use the other connector to attach another SCSI device or, if the drive is at the end of the bus, to connect a terminator plug. Secure the cable with the guide hooks on both the drive and adapter connectors, if provided.

Note

A SCSI device should include some means of terminating the bus, when necessary. The terminator might take the form of a cableless plug you connect to the second SCSI connector on the drive, or the drive might be self-terminating, in which case there should be a jumper or a switch you can set to activate termination.

Finally, your external drive should have a SCSI ID select switch on the back. This switch sets the identification number the host adapter uses to distinguish the drive from the other devices on the bus. The host adapter, by most manufacturers' defaults, should be set for SCSI ID 7, and some (but not all) manufacturers reserve the IDs 0 and 1 for use by hard disk drives. Be sure you set the SCSI ID for the CD-ROM or DVD-ROM drive to any other number—6, 5, or 4, for example. The only rule to follow is

to be sure you do not set the drive for an ID that is already occupied—by either the adapter or any other SCSI peripheral on the bus.

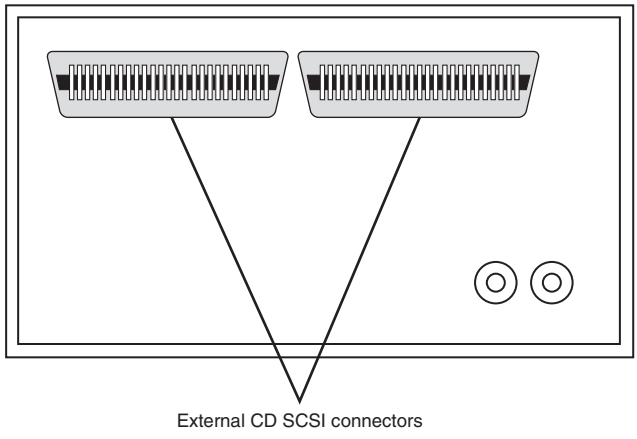

Figure 14.8 External drive with dual SCSI connectors.

Internal Drive Installation

Unpack your internal drive kit. You should have the following pieces:

- The drive
- The internal CD-audio cable
- Floppy disks/CD-ROM with device driver software and manual
- Drive rails and mounting screws

Your manufacturer also might have provided a power cable splitter—a bundle of wires with plastic connectors on each of three ends. A disc caddy and owner's manual might also be included. If you do not already have one in the computer, you also will need a SCSI host adapter to connect SCSI peripherals.

Make sure the PC is turned off, and remove the cover from the case. Before installing a SCSI adapter into the PC's expansion bus, connect the SCSI ribbon cable to the adapter card (see Figure 14.9).

Ribbon Cable and Card Edge Connector

The ribbon cable should be identical on both ends. You'll find a red stripe or dotted line down one side of the outermost edge of the cable. This stripe indicates a pin-1 designation and ensures that the SCSI cable is connected properly to the card and drive. If you're lucky, the manufacturer has supplied a cable with notches or keys along one edge of the connector. With such a key, you can insert the cable into the card and drive in only one way. Unkeyed cables must be hooked up according to the pin-1 designation.

Along one edge of your SCSI adapter is a double row of 50 brass-colored pins. This is the card edge connector. In small print along the base of this row of pins you should find at least two numbers next to the pins—1 and 50. Aligning the ribbon cable's marked edge over pin 1, carefully and evenly insert the ribbon cable connector.

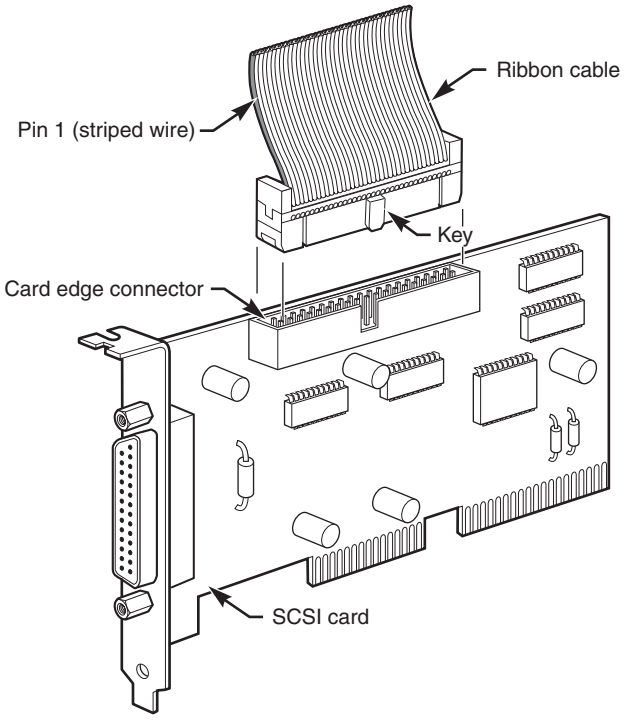

Figure 14.9 Connecting a ribbon cable to a SCSI adapter.

Next, insert the adapter card into a free bus slot in the computer, leaving the drive end of the cable loose for the time being.

Choose a bay in the front of your computer's case for your internal drive. Make sure it's easily accessible from the outside and not blocked by other items on your desk. You'll be inserting the CDs or DVDs here, and you'll need the elbow room.

Remove the drive bay cover from the computer case. You might have to loosen some screws to do this, or the cover might just pop off. Inside the drive bay, you should find a metal enclosure with screw holes for mounting the drive. If the drive has mounting holes along its side and fits snugly into the enclosure, you won't need mounting rails. If it's a loose fit, however, mount the rails along the sides of the drive with the rail screws, and then slide the drive into the bay. Secure the drive into the bay with four screws—two on each side. If the rails or drive don't line up evenly with four mounting holes, be sure you use at least two screws—one mounting screw on each side. Because you'll be inserting and ejecting many discs over the years, mounting the drive securely is a must.

Once again, find the striped side of the ribbon cable and align it with pin 1 on the drive's edge connector. Either a diagram in your owner's manual or a designation on the connector itself tells you which is pin 1.

The back of the drive has a four-pin power connector outlet. Inside the case of your PC, at the back of your floppy or hard disk, are power cords—bundled red and yellow wires with plastic connectors on them. You might already have a power connector lying open in the case. Take the open connector and plug it into the back of the power socket on the CD-ROM or DVD-ROM drive. These

connectors can go in only one way. If you do not have an open connector, use a drive power splitter (refer to Figure 14.4). Disconnect an existing drive power cord from the device that uses the least power. Next, attach the splitter to the detached power cord. Plug one of the free ends back into the drive you removed the power from and plug the other into the CD-ROM or DVD-ROM drive.

Note

It's preferable to "borrow" power from the drive that consumes the least power so you don't overload the connection. Check the specification sheets for your drives to determine their power consumption. In general, devices that are physically smaller or that spin more slowly draw less power. If you have no choice—if the splitter and ribbon cable won't reach, for example—you can split off any power cord that hasn't already been split. Check the power cable to ensure that you have a line not already overloaded with another splitter.

Do not replace the PC cover yet—you need to make sure that everything is running perfectly before you seal the case. You're now ready to turn on the computer. If everything runs normally, it's time to put that cover back on.

SCSI Chains: Internal, External, or Both

Remember, one of the primary reasons for using the SCSI interface for your CD-ROM or DVD-ROM drive is the capability to connect a string of peripherals from one adapter, thus saving card slots inside the PC and limiting the nightmare of tracking IRQs, DMAs, and I/O memory addresses.

You can add hard drives, scanners, tape backup units, and other SCSI peripherals to this chain (see Figure 14.10). You must keep a few things in mind, however, and chief among them is SCSI termination.

◀◀ See "Termination," p. 556.

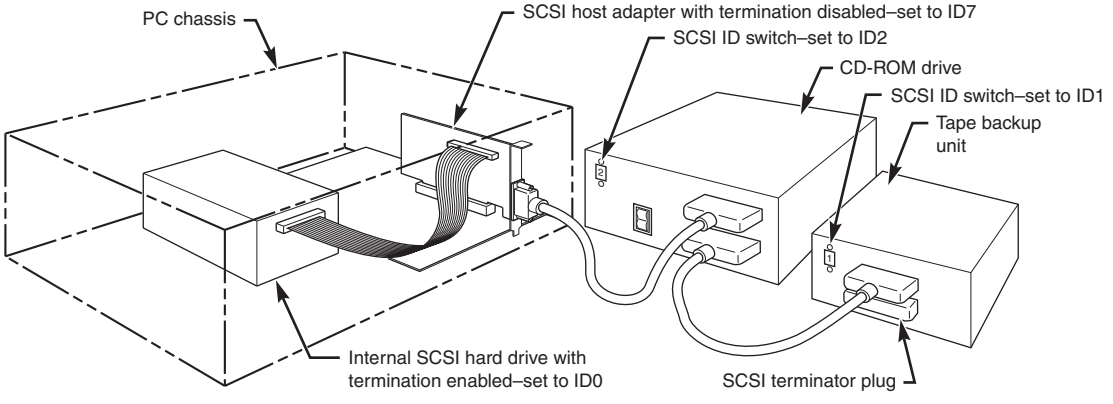

Figure 14.10 A SCSI chain of devices on one adapter card.

Example One: All External SCSI Devices. Say that you installed your CD-ROM or DVD-ROM drive and added a tape device to the SCSI bus with the extra connector on the back of the optical drive. The first device in this SCSI bus is the adapter card itself. Most modern host adapters are *autoterminating*, meaning they will terminate themselves without your intervention if they are at the end of the bus.

From the card, you ran an external cable to the optical drive, and from the optical drive, you added another cable to the back of the tape unit. You must now terminate the tape unit as well. Most external units are terminated with a SCSI cap—a small connector that plugs into the unused external SCSI connector. These external drive connectors come in two varieties: a SCSI cap and a pass-through terminator. The cap is just that; it plugs over the open connector and covers it. The pass-through terminator, however, plugs into the connector and has an open end into which you can plug the SCSI cable. This type of connector is essential if your external drive has only one SCSI connector; you can plug the drive in and make sure it's terminated—all with one connector.

Example Two: Internal Chain and Termination. On an internal SCSI bus, the same rules apply: All the internal devices must have unique SCSI ID numbers, and the first and last devices must be terminated. In the case of internal devices, however, you must check for termination. Internal devices typically have DIP switches or terminator packs similar to those on your adapter card. If you install a tape unit as the last device on the chain, it must have some means of terminating the bus. If you place your optical drive in the middle of the bus, you must deactivate its termination. The host adapter at the end of the chain must still be terminated.

Note

Most internal SCSI devices ship with terminating resistors or DIP switches onboard, usually the latter. Check your user manuals for their locations. Any given device can have one, two, or even three such resistors.

Example Three: Internal and External SCSI Devices. If you mix and match external as well as internal devices, follow the same rules. The bottom example shown in Figure 14.11 has an internal CD-ROM drive, terminated and set for SCSI ID 6; the external hard drive also is terminated and is using SCSI ID 5. The SCSI adapter itself is set for ID 7 and, most importantly, its termination has been disabled because it is no longer at the end of the bus.

Note

As with any adapter card, be careful when handling the card itself. Be sure to ground yourself first.

To help you determine whether your SCSI interface card and devices are functioning properly, Adaptec supplies a utility program called SCSI Interrogator. Use it to determine which logical unit numbers (LUNs) are available for new devices.

If you don't see any devices listed, you might have a termination problem. Shut down your system and your devices. Then, check terminator plugs, switches, or resistor packs. If they appear correct, turn on the external devices about 5 seconds before you start the system. A multiswitch power director with high-quality surge protection works well for this because it allows you to turn on individual devices. If the devices fail to show up after you restart the system, you might have a problem with the SCSI BIOS or device driver software. Check the documentation for your particular card and device to ensure you have installed the proper drivers.

One peculiarity of the Adaptec SCSI Interrogator is that it lists a "host adapter #1" that's actually your ATA interface! If your SCSI card isn't working, both "host adapter #0" and "host adapter #1" are actually ATA. You can tell whether this is happening with Windows 9x because it will list "ESDI_506" as the driver version.

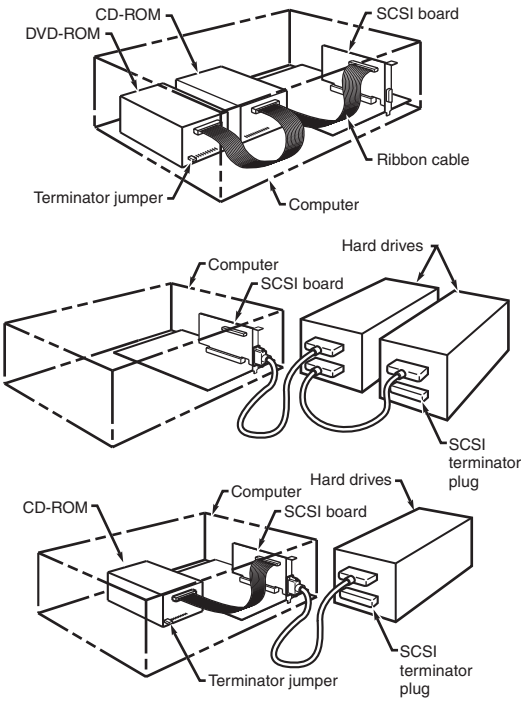

Figure 14.11 Examples of various SCSI termination scenarios.

Floppy Drive Installation Procedures

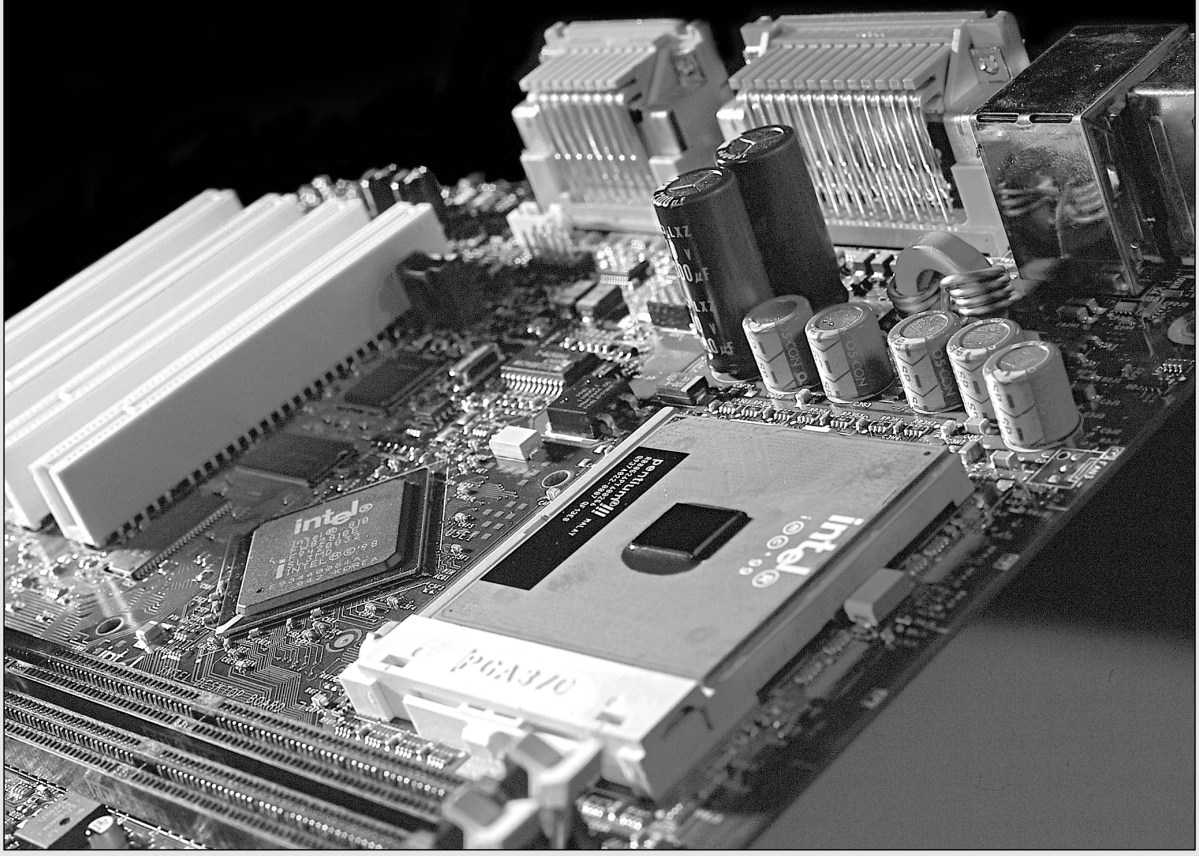
A floppy drive is one of the simplest types of drives to install. In most cases, installing a floppy disk drive is a matter of attaching the drive to the computer chassis or case and then plugging the power and signal cables into the drive. Some type of brackets and screws are usually required to attach the drive to the chassis; however, some chassis are designed to accept the drive with no brackets at all. Any brackets, if necessary, are normally included with the chassis or case itself. Several companies listed in the Vendor List on the DVD specialize in cases, cables, brackets, screw hardware, and other items useful in assembling systems or installing drives.

Note

Because floppy disk drives are generally installed into the same half-height bays as hard disk drives, the physical mounting of the drive in the computer case is the same for both units. See the section "Hard Disk Installation Procedures," earlier in this chapter, for more information on the process.

When you connect the drive, make sure the power cable is installed properly. The cable is usually keyed so you can't plug it in backward, but the keying can be defeated by somebody forcing the connection. If that is done, the drive will be fried the instant the power is turned on.

Next, install the interface cable. A floppy interface cable is a 34-pin cable that typically has a twist in it. What I mean is that pins 10–16 are twisted around before they reach the last (A:) drive connector. Normally, the A: drive must be plugged in after this twist; any drive plugged into a connector before



the twist is seen by the system as drive B:. The twist reverses the drive select and motor enable signals, letting A: and B: drives coexist without rejumpering. This is similar to the way Cable Select works for ATA/IDE drives. Because of this, all floppy drives are jumpered the same way, in the second Drive Select (DS) position.

Older drives used to require various jumpers to be set to enable the drive to work properly. The two most common jumpers were the Drive Select jumper and the Disk Change (DC) jumper. If you encounter an older drive with these jumpers, you should follow a few simple rules. The DS jumper typically has two positions, labeled 0 and 1—or in some cases, 1 and 2. In all PC installations, the DS jumper should be set on the second position, no matter what it is numbered. This enables the drive on the cable before the twist to function as drive B: and the drive at the end of the cable after the twist to function as drive A:. The DC jumper setting is normally an on or off setting. For PC use, if the drive has a DC jumper, it must be set on or enabled. This enables the PC to detect when you have changed disks in the drive. For more information on floppy drives and interfacing, see Chapter 11.

The interface cable is usually keyed to prevent backward installation. If no key exists in this cable, use the colored wire in the cable as a guide to the position of pin 1. Normally, pin 1 is oriented closest to the power connector, which is the same as other drives. If the drive LED stays on continuously when you power up the system or when the system is running, that is a sure sign you have the floppy cable on backward either at the drive end or at the controller (motherboard) end.

CHAPTER 15

Video Hardware

Video Display Technologies

Along with the mouse and keyboard, the video display is a vital part of the user interface of any computer. Actually, it is a latecomer to computing; before CRT monitors came into general use, the teletypewriter was the standard computer interface—a large, loud device that printed the input and output characters on a roll of paper. The first CRT displays used on computers were primitive by today's standards; they displayed only text in a single color (usually green), but to users at the time they were a great improvement, allowing real-time display of input and output data. Over time, color displays were introduced, screen sizes increased, and LCD technologies moved from the portable computer to the desktop.

Today, PC video displays are much more sophisticated, but you must be careful when selecting video hardware for your computer. A slow video adapter can slow down even the fastest and most-powerful PC. Incorrect monitor and video adapter combinations can also cause eyestrain or be unsuitable for the tasks you want to accomplish.

The video subsystem of a PC consists of two main components:

- *Monitor (or video display).* The monitor can be either a CRT or an LCD panel.
- *Video adapter (also called the video card or graphics adapter).* On many recent low-cost systems, video might be built into the motherboard or included as part of this motherboard's chipset.

This chapter explores the range of PC video adapters on the market today and the displays that work with them. The remainder of this section covers the various types of display technologies.

Note

The term *video*, as it is used in this context, does not necessarily imply the existence of a moving image, such as on a television screen. All adapters that feed signals to a monitor or other display are video adapters, regardless of whether they are used with applications that display moving images, such as multimedia or video-conferencing software.

How CRT Display Technology Works

A monitor can use one of several display technologies. The original display technology, and still the most popular, is cathode ray tube (CRT) technology—the same technology used in television sets. CRTs consist of a vacuum tube enclosed in glass. One end of the tube contains an electron gun assembly that projects three electron beams, one each for the red, green, and blue phosphors used to create the colors you see onscreen; the other end contains a screen with a phosphorous coating.

When heated, the electron gun emits a stream of high-speed electrons that are attracted to the other end of the tube. Along the way, a focus control and deflection coil steer the beam to a specific point on the phosphorous screen. When struck by the beam, the phosphor glows. This light is what you see when you watch TV or look at your computer screen. Three layers of phosphors are used: red, green, and blue. A metal plate called a *shadow mask* is used to align the electron beams; it has slots or holes that divide the red, green, and blue phosphors into groups of three (one of each color). Various types of shadow masks affect picture quality, and the distance between each group of three (the *dot pitch*) affects picture sharpness.

▶▶ See "Dot Pitch (CRTs)," p. 863.

Figure 15.1 illustrates the interior of a typical CRT.

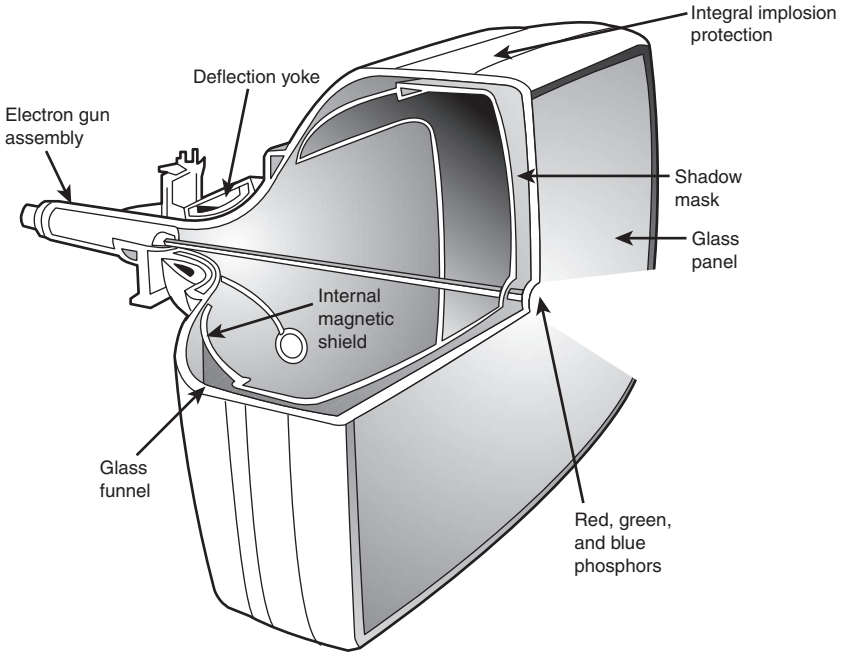


Figure 15.1 A typical CRT monitor is a large vacuum tube. It contains three electron guns (red, green, and blue) that project the picture toward the front glass of the monitor. High voltage is used to produce the magnetism that controls the electron beams that create the picture displayed on the front of the CRT.

The phosphor chemical has a quality called *persistence*, which indicates how long this glow remains onscreen. Persistence is what causes a faint image to remain on your TV screen for a few seconds after you turn the set off. The scanning frequency of the display specifies how often the image is refreshed. You should have a good match between persistence and scanning frequency so the image has less flicker (which occurs when the persistence is too low) and no ghost images (which occurs when the persistence is too high).

The electron beam moves very quickly, sweeping the screen from left to right in lines from top to bottom, in a pattern called a *raster*. The horizontal scan rate refers to the speed at which the electron beam moves laterally across the screen.

During its sweep, the beam strikes the phosphor wherever an image should appear onscreen. The beam also varies in intensity to produce different levels of brightness. Because the glow begins to fade almost immediately, the electron beam must continue to sweep the screen to maintain an image—a practice called *redrawing* or *refreshing* the screen.

Most current CRT displays have an ideal refresh rate (also called the vertical scan frequency) of about 85 hertz (Hz), which means the screen is refreshed 85 times per second. Refresh rates that are too low cause the screen to flicker, contributing to eyestrain. The higher the refresh rate, the better for your eyes. Low-cost monitors often have flicker-free refresh rates available only at 640×480 and 800×600 resolutions; you should insist on high refresh rates at resolutions such as 1,024×768 or higher.

It is important that the refresh rates expected by your monitor match those produced by your video card. If you have mismatched rates, you will not see an image and can actually damage your monitor. Generally speaking, video card refresh rates cover a higher range than most monitors. For this reason,

the default refresh rate used by most video cards is relatively low (usually 60Hz) to avoid monitor damage. The refresh rate can be adjusted through the Windows display properties sheets.

Multiple Frequency Monitors

Although a few very old monitors had fixed refresh rates, most monitors support a range of frequencies. This support provides built-in compatibility with a wide range of current and future video standards (described in the "Video Display Adapters" section later in this chapter). A monitor that supports many video standards is called a *multiple-frequency monitor*. Virtually all monitors sold today are multiple frequency, which means they support operation with a variety of popular video signal standards. Different vendors call their multiple-frequency monitors by different trade names, including multisync, multifrequency, multiscan, autosynchronous, and autotracking.

Note

Even though a monitor is capable of displaying a wide range of video standards, you usually need to fine-tune the display to achieve the best possible pictures.

Curved Versus Flat Picture Tubes

Phosphor-based screens come in two styles: curved and flat. Until recently, the typical display screen has been curved; it bulges outward from the middle of the screen. This design is consistent with the vast majority of CRT designs (the same as the tube in most television sets). Although this type of CRT is inexpensive to produce, the curved surface can cause distortion and glare, especially when used in a brightly lit room. Some vendors use antiglare treatments to reduce the reflectivity of the typical curved CRT surface.

The traditional screen is curved both vertically and horizontally. Some monitor models use the Sony Trinitron CRT, some versions of which are curved only horizontally and flat vertically; these are referred to as *flat square tube (FST)* designs.

Most manufacturers are now selling monitors featuring CRTs that are flat both horizontally and vertically. Sony's FD Trinitron, NEC-Mitsubishi's DiamondTron NF, and ViewSonic's PerfectFlat are some of the more popular flat CRT designs, the first such screens for PCs since the short-lived Zenith FTM monitors of the late 1980s. Many people prefer this type of flatter screen because these picture tubes show less glare and provide a higher-quality, more accurate image. Although flat-screen CRTs are slightly more expensive than conventional curved CRTs, they are only one-third to one-half the price of comparably sized flat-panel LCD displays.

Figure 15.2 compares the cross-section of typical curved and flat CRT picture tubes.

DVI—Digital Signals for CRT Monitors

The latest trend in CRT monitor design is the use of digital input signals using the same Digital Video Interface (DVI) standard used for LCD flat-panel displays. Although several major monitor vendors announced support for DVI-I interfaces for their CRT monitors in 1999, most CRT monitors (except for a few 19" or larger high-end monitors) continue to use the conventional 15-pin analog VGA connector. CRT monitors that use the DVI-I connector—unlike the TTL digital displays of the 1980s that supported only a few colors—support the same unlimited color spectrum as analog CRTs. Users benefit from digital displays because these displays can feature better picture quality, better signal reception, and precise auto setup.

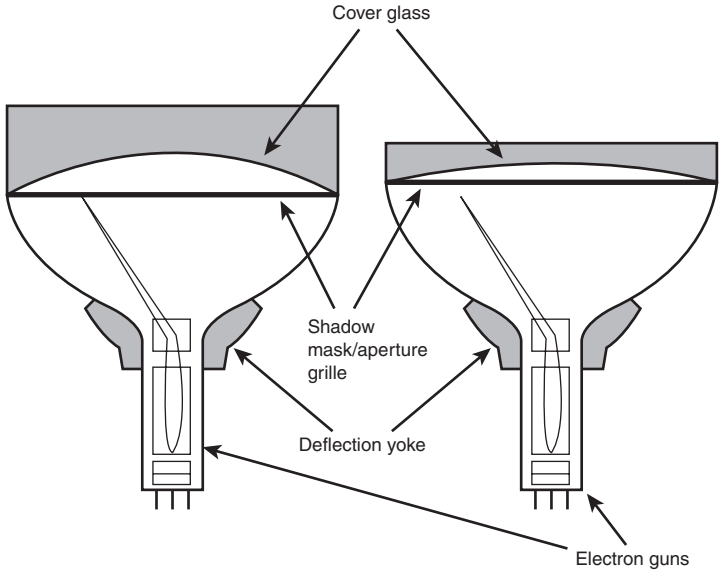

Figure 15.2 A typical curved-tube CRT (left) compared to a Sony Trinitron FD flat tube (right).

Because most low-end and mid-range video cards still feature only analog (DB-15) VGA connectors, many of these monitors feature both analog and 20-pin DVI interfaces. However, as all-digital LCD display panels that also use the DVI interface increase in popularity, analog VGA eventually might be replaced by DVI-based CRT and LCD displays.

▶▶ See "Flat-Panel LCD Monitors," p. 856.

LCD Panels

Borrowing technology from laptop manufacturers, most major monitor makers sell monitors with liquid crystal displays (LCDs). LCDs have low-glare, completely flat screens and low power requirements (5 watts versus nearly 100 watts for an ordinary monitor). The color quality of an active-matrix LCD panel actually exceeds that of most CRT displays.

At this point, however, LCD screens usually are more limited in resolution than typical CRTs. For example, a typical 15" LCD panel (which offers about the same viewable area as a 17" CRT display) has a maximum resolution of 1,024×768, whereas a typical 17" CRT might offer a maximum resolution of 1,280×1,024 or 1,600×1,200. 17" and 18" LCD panels (comparable in viewing area to 19" CRTs) have also become popular. However, these larger LCD panels offer a maximum resolution of 1,280×1,024, whereas a typical 19" CRT has a maximum resolution of 1,600×1,200.

Despite recent price drops, LCD panels continue to be more expensive than comparably sized CRTs. A typical 15" LCD display panel sells for around $350–$550, compared to flat-screen 17" CRTs, which sell for around $200–$450. However, it is important to consider that an LCD screen provides a larger viewable image than a CRT monitor of the same size. See Figure 15.3 for an example of a typical desktop LCD display panel.

Figure 15.3 A typical example of a 15" LCD display panel. Note the small footprint, which makes LCD panels ideal for use in cramped quarters.

Two basic LCD choices are available today on notebook computers: active-matrix analog color and active-matrix digital—the latest development. Monochrome LCD displays are obsolete for PCs, although they remain popular for Palm and similar organizer devices and are sometimes used for industrial display panels. Passive-matrix displays using dual-scan technology were popular for low-cost notebook models until recently, but most low-cost notebooks sold today use the brighter analog or digital active-matrix designs originally found on more expensive notebook computers. Passive-matrix displays are still used with handheld organizers or for industrial-use desktop display panels because of their relatively low cost and enhanced durability compared to active-matrix models.

Note

The most common type of passive-matrix display uses a supertwist numatic design, so these panels are often referred to as STNs. Active-matrix panels usually use a thin-film transistor design and are thus referred to as TFTs.

Desktop LCD panels are analog or digital active-matrix units. Typically, lower-cost 15" LCD panels use the traditional analog VGA connector and must convert analog signals back into digital, whereas more expensive 15" and most larger LCD panels provide both the analog VGA and the DVI digital connector found on many high-end and mid-range video cards. Note that some LCD vendors of VGA/DVI-compatible panels might provide only the cheaper analog VGA cable, leaving it to you to buy your own DVI cable. If you plan to connect your new LCD display to your video card's DVI port, be sure that the panel supports DVI and that the cable is included. And, while you're shopping for an LCD panel, be sure to note which models include the DVI cable; the presence of a DVI cable in the box of a nominally more expensive display can more than make up the difference in price between it and an apparently less expensive panel that doesn't include the cable.

How LCDs Work

In an LCD, a polarizing filter creates two separate light waves. The polarizing filter allows light waves that are aligned only with the filter to pass through. After passing through the polarizing filter, the remaining light waves are all aligned in the same direction. By aligning a second polarizing filter at a right angle to the first, all those waves are blocked. By changing the angle of the second polarizing filter, the amount of light allowed to pass can be changed. It is the role of the liquid crystal cell to change the angle of polarization and control the amount of light that passes. The liquid crystals are rod-shaped molecules that flow like a liquid. They enable light to pass straight through, but an electrical charge alters their orientations and the orientation of light passing through them. Although monochrome LCDs do not have color filters, they can have multiple cells per pixel for controlling shades of gray.

In a color LCD, an additional filter has three cells for each pixel—one each for displaying red, green, and blue—with a corresponding transistor for each cell. The red, green, and blue cells, which make up a pixel, are sometimes referred to as *subpixels*. The ability to control each cell individually has enabled Microsoft to develop a new method of improving LCD text quality. Beginning with Windows XP, you can enable a feature called ClearType through the Display properties sheet. However, individual cells can also fail.

Dead Pixels

A so-called *dead pixel* is one in which the red, green, or blue cell is stuck on or off. Failures in the on state are more common. In particular, those that fail when on are very noticeable on a dark background, such as bright red, green, or blue dots. Although even a few of these can be distracting, manufacturers vary in their warranty policies regarding how many dead pixels are required before you can get a replacement display. Some vendors look at both the total number of dead pixels and their locations. Fortunately, improvements in manufacturing quality make it less and less likely that you will see a screen with dead pixels either on your desktop or in your notebook computer display.

Although there is no normal way to repair bad pixels, there might be a simple fix that can help. I have actually repaired bad pixels by gently tapping on the screen at the pixel location. This seems to work in many cases, especially in cases in which the pixel is always illuminated instead of dead (dark). Because I find a constantly lit pixel to be more irritating than one that is constantly dark, this fix has saved me a lot of aggravation.

Active-Matrix Displays

Most active-matrix displays use a thin film transistor (TFT) array. TFT is a method for packaging from one (monochrome) to three (RGB color) transistors per pixel within a flexible material that is the same size and shape as the display. Therefore, the transistors for each pixel lie directly behind the liquid crystal cells they control.

Two TFT manufacturing processes account for most of the active-matrix displays on the market today: hydrogenated amorphous silicon (a-Si) and low-temperature polysilicon (p-Si). These processes differ primarily in their costs. At first, most TFT displays were manufactured using the a-Si process because it required lower temperatures (less than 400°C) than the p-Si process of the time. Now, lower-temperature p-Si manufacturing processes are making this method an economically viable alternative to a-Si.

To improve horizontal viewing angles in the latest LCD displays, some vendors have modified the classic TFT design. For example, Hitachi's in-plane switching (IPS) design—also known as STFT—aligns the individual cells of the LCD parallel to the glass, running the electric current through the sides of the cells and spinning the pixels to provide more even distribution of the image to the entire panel area. Hitachi's Super-IPS technology also rearranges the liquid crystal molecules into a zig-zag pattern, rather than the typical row-column arrangement, to reduce color shift and improve color uniformity. The similar multidomain vertical alignment (MVA) technology developed by Fujitsu divides the screen into different regions and changes the angle of the regions.

Both Super-IPS and MVA provide a wider viewing angle than traditional TFT displays. Because larger LCD displays (17" and wider) are large enough to cause shifts in viewing angle even for an individual user, these advanced technologies are being used primarily on larger and more expensive panels and have been licensed to other display vendors.

Passive-Matrix Displays

In a passive-matrix LCD, such as you would find on older and less expensive notebook computers, each cell is controlled by the electrical charges of two transistors, determined by the cell's row and column positions on the display. The number of transistors along the screen's horizontal and vertical edges determines the resolution of the screen. For example, a screen with a 1,024×768 resolution has 1,024 transistors on its horizontal edge and 768 on the vertical, for a total of 2,000. As the cell reacts to the pulsing charge from its two transistors, it twists the light wave, with stronger charges twisting the light wave more. *Supertwist* refers to the orientation of the liquid crystals, comparing on mode to off mode—the greater the twist, the higher the contrast.

Charges in passive-matrix LCDs are pulsed; therefore, the displays lack the brilliance of active-matrix, which provides a constant charge to each cell. To increase the brilliance, virtually all vendors have turned to a technique called *double-scan LCD*, which splits passive-matrix screens into a top half and bottom half, reducing the time between each pulse. In addition to increasing the brightness, dual-scan designs also increase the response time and therefore the perceptible speed of the display, making this type more usable for full-motion video or other applications in which the displayed information changes rapidly.

Comparing Active-Matrix and Passive-Matrix Displays

In an active-matrix LCD, such as those used on most current notebook computer displays and all desktop LCD panels, each cell has its own dedicated transistor behind the panel to charge it and twist the light wave. Thus, a 1,024×768 active-matrix display (the most common resolution for 15" LCD panels and notebook computer displays) has 786,432 transistors. This provides a brighter image than passive-matrix displays because the cell can maintain a constant, rather than a momentary, charge. However, active-matrix technology uses more energy than passive-matrix, leading to shorter battery life on portable systems. With a dedicated transistor for every cell, active-matrix displays are more difficult and expensive to produce, but in return they offer a faster display that can be used in outdoor as well as indoor conditions and at wider viewing angles than dual-scan displays.

Note

Because an LCD display requires a specified number of transistors to support each cell, there are no multiple frequency displays of this type. All the pixels on an LCD screen are of a fixed size, although CRT pixels are variable. Thus, LCD displays are designed to be operated at a specific resolution; however, most recent notebook and desktop display panels offer onboard scaling. Before purchasing this type of display, be sure your video adapter supports the same resolution as the screen and that the resolution is sufficient for your needs throughout the life of the monitor.

In both active- and passive-matrix LCDs, the second polarizing filter controls how much light passes through each cell. Cells twist the wavelength of light to closely match the filter's allowable wavelength. The more light that passes through the filter at each cell, the brighter the pixel.

Monochrome LCDs used in handheld organizers and industrial LCD panels achieve grayscales (up to 64) by varying the brightness of a cell or dithering cells in an on-and-off pattern. Color LCDs, on the other hand, dither the three-color cells and control their brilliance to achieve different colors on the screen. Double-scan passive-matrix LCDs (also known as DSTN) have been used in some lower-cost notebook models in recent years because they approach the quality of active-matrix displays but do not cost much more to produce than other passive-matrix displays. Although DSTN panels offer better on-axis (straight-ahead) viewing quality than straight passive-matrix panels, their off-axis (viewing at an angle) performance is still poor when compared to active-matrix (TFT) panels. Most low-cost notebook computer lines, which formerly used DSTN or other passive-matrix designs, have now switched over to TFT active-matrix displays.

Note

An alternative to LCD screens is gas-plasma technology, typically known for its black and orange screens in some of the older Toshiba notebook computers. Some companies are incorporating full-color gas-plasma technology for desktop screens and color high-definition television (HDTV) flat-panel screens, such as the Philips Flat TV. At this point, full-color gas-plasma technology is not cost-effective for computer displays.

Historically, the big problem with active-matrix LCDs has been that the manufacturing yields are lower than for passive-matrix LCDs, forcing higher prices. This means many of the panels produced have more than a certain maximum number of failed transistors. The resulting low yields limit the production capacity and incur somewhat higher prices. Recent improvements in technology and more factories producing LCD panels have helped prices for both notebook computers and desktop LCD panels to drop significantly. As a result, prices have dropped below $400 for some of the newest 15" desktop LCD display panels and for the use of active-matrix LCDs in almost all notebook computers now on the market.

In the past several hot, miniature CRTs were needed to light an LCD screen, but portable computer manufacturers now use a single tube the size of a cigarette. Fiber-optic technology evenly spreads light emitted from the tube across an entire display.

Thanks to supertwist and triple-supertwist LCDs, today's screens enable you to see the screen clearly from more angles with better contrast and lighting. To improve readability, especially in dim light, virtually all laptops include backlighting or edgelighting (also called sidelighting). Backlit screens provide light from a panel behind the LCD. Edgelit screens get their light from small fluorescent tubes mounted along the sides of the screen. Some older laptops excluded such lighting systems to lengthen battery life. Power-management features incorporated into notebook computers enable you to run the backlight at a reduced power setting that dims the display but allows for longer battery life.

Flat-Panel LCD Monitors

LCD desktop monitors, once seen mainly on the office sets of futuristic TV shows, are now becoming an increasingly reasonable choice for use in today's office computing environment. Many users with dual-display-capable video cards have added an LCD panel as a second monitor or use one as their only monitor.

LCD monitors offer a number of benefits when compared to conventional CRT "glass tube" monitors. LCD panels feature a larger effective viewable area than CRTs; a 15" LCD is essentially equal in usability to a 17" CRT. Because LCDs use direct addressing of the display (each pixel in the picture corresponds with a transistor), they produce a high-precision image. LCDs can't have the common CRT display problems of pin-cushion, barrel distortion, or convergence errors (halos around the edges of onscreen objects).

LCD panels are less expensive to operate because they feature lower power consumption and much less heat buildup than CRTs. Because LCD units lack a CRT, no concerns exist about electromagnetic VLF or ELF emissions.

LCD panels offer a smaller footprint (front-to-back dimensions), and some offer optional wall or stand mounting. Several LCD panels offer a pivoting feature, enabling the unit to swivel 90° and providing a choice between the traditional landscape horizontal mode for Web surfing and the portrait vertical mode for word processing and page-layout programs. LCD panels weigh substantially less than comparably sized CRTs. For example, the ViewSonic VG150, a 15" LCD display, weighs only 11 lbs., compared to the 35 lbs.–50 lbs. weight of typical 17" CRTs.

There are two major proposals for digital LCD display panel standards:

- *The Digital Flat Panel (DFP) standard approved by the Video Electronic Standards Association (VESA) in February 1999.* DFP was previously known as PanelLink; DFP has now been replaced by DVI.
- *The Digital Visual Interface (DVI) standard proposed by the Digital Display Working Group (DDWG) in April 1999.* DVI is much more popular with hardware vendors and has become a de facto standard supported by most recent mid-range and high-end VGA display cards.

Figure 15.4 shows how DFP and DVI connectors found on some video cards and digital LCD displays compare to the standard VGA connector used on conventional video cards, CRTs, and analog-compatible LCD displays.

Before you rush to the store to purchase an LCD desktop monitor, you should consider several potential drawbacks:

- *If you routinely switch display resolutions (as Web developers do to preview their work), LCD monitors must take one of two approaches to change resolutions.* Some older units might reduce the onscreen image to occupy only the pixels of the new resolution, thus using only a portion of a typical 1,024×768 LCD panel to display a 640×480 image, whereas newer units might scale the image to occupy the entire screen. Scaling is becoming more common because the Digital Display Work Group standard for LCD desktop displays specifies that the scaling must take place in the display panel, the graphics controller, or both places. Look at the quality of a scaled image if using different resolutions is important to you.
- *If you choose an analog LCD panel, you'll usually save money and be able to use your existing video card or onboard video port.* However, image quality for both text and graphics can suffer because of the conversion of the computer's digital signal to analog (at the video card) and back to digital again (inside the LCD panel). The conversion can lead to pixel jitter or pixel swim, in which adjacent LCD cells are turned on and off by the display's incapability to determine which cells should stay on and stay off. Most panels come with adjustment software to reduce this display-quality problem, but you might not be able to eliminate it entirely.

- *Digital LCD panels avoid conversion problems when attached to a digital-compatible display card.* However, most low-cost off-the-shelf display cards don't support digital signals yet, and the onboard video circuits built into some motherboards don't support DVI yet.

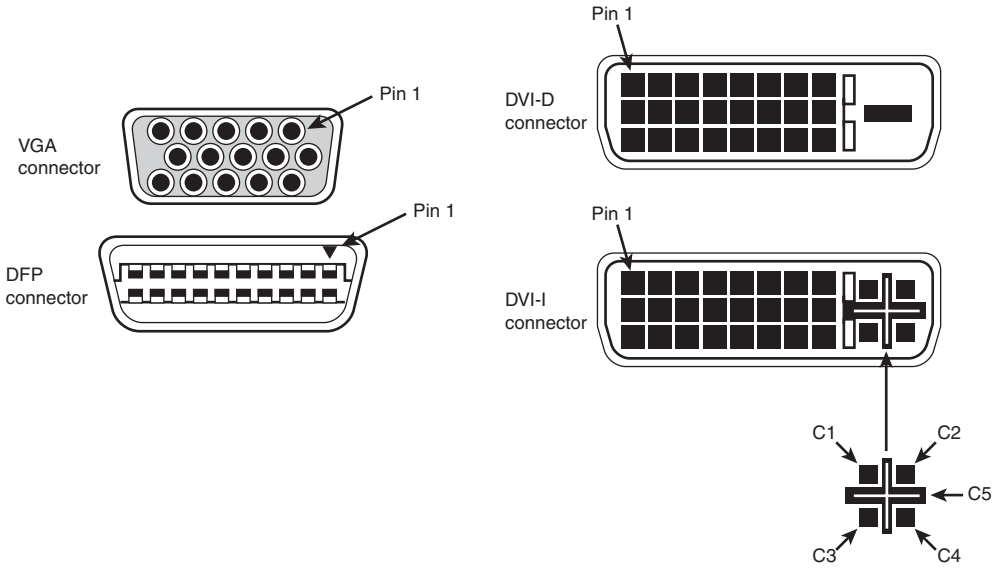

Figure 15.4 Conventional VGA cards, CRTs, and analog-compatible LCD displays use the standard VGA connector. Early digital LCDs and their matching video cards often used the DFP connector. Most recent digital LCD panels use the DVI-D connector, whereas video cards used with both analog and digital displays use the DVI-I connector.

Note

Video card and chipset makers, such as NVIDIA, Matrox, and ATI, have added support for digital and analog display panels to their newest 3D chipsets and video cards.

- *High-quality LCD display panels of either digital or analog type are great for displaying sharp text and graphics.* But they often can't display as wide a range of very light and very dark colors as CRTs can.
- *Many LCD displays don't react as quickly as CRTs.* This can cause full-motion video, full-screen 3D games, and animation to look smeared onscreen. To avoid this problem, look for LCD displays that use a faster response liquid-crystal material. ViewSonic's name for its faster material is 3X-LCD.

Thanks to price decreases, larger panel sizes, and widespread support for DVI digital connectors on current video cards, this is the best time ever to consider buying an LCD panel for your desktop PC.

Be sure that you use the following criteria when you consider purchasing an LCD monitor:

- *Evaluate the panel both at its native resolution and at any other resolutions you plan to use.*
- *If you're considering a digital LCD panel, determine whether your existing video card supports the features you need.* Features you might find necessary include OpenGL and high-speed 3D support (for gaming), VGA-to-TV support (for video producers), and DVD playback software (for watching DVD movies). Because most mid-range and high-end video cards based on the latest NVIDIA and ATI chipsets do offer a DVI port for connection with current and forthcoming digital LCD panels, you can upgrade to a high-performance video card that will support your display. Even though some notebook computers now support DVI displays, most still feature only analog VGA connectors.
- *Look for displays that support both analog and DVI inputs if you want to use the same display on different systems.* Because LCD panels are much lighter and smaller than normal CRT displays, they're a natural choice for connecting to both desktop and notebook computers. If you use multiple computers in a small work area, you might also want to look for displays that support multiple inputs, which enables you to connect two computers to one screen.
- *Make sure your system has a suitable expansion slot for the recommended video card type.* Many low-cost systems today feature onboard AGP video but no AGP slot, which can't be upgraded unless the user opts for the obsolescent (for video) PCI slot. As the move to LCD panels continues, more of these systems should feature built-in support for LCD displays, but this could be a problem for some time to come. NVIDIA's nForce and ATI's RADEON IGP integrated graphics chipsets support both DVI and analog VGA displays.
- *Evaluate the panel and card combo's performance on video clips and animation if you work with full-motion video, animated presentation programs, or games.*
- *Although active-matrix (analog) and digital LCD monitors have much wider viewing areas than do passive-matrix and dual-scan LCD panels used in low-cost notebook computers, their viewing angles are still usually much less than CRTs.* This is an important consideration if you're planning to use your LCD monitor for group presentations. To improve the horizontal viewing area, several vendors have developed patented improvements to the basic TFT display, such as Hitachi's in-plane switching (IPS) and Fujitsu's multidomain vertical adjustment (MVA), both of which have been licensed to other leading LCD display makers.
- *A high-contrast ratio (luminance difference between white and black) makes for sharper text and vivid colors.* A typical CRT has a contrast ratio of about 245:1. Although LCD panels in the May 23, 2000 *PC Magazine* test had contrast ratios ranging from a low of 186:1 to a high of 370:1, newer LCD panels have even higher contrast ratios (up to 400:1). Panels could be viewed at an average horizontal angle of as much as 129° without loss of contrast.
- *Features such as integrated speakers and Universal Serial Bus (USB) hubs are pleasant additions, but your eyes should make the final decision about which panel is best for you.* Because reviews of LCD panels often don't provide detailed analysis of horizontal and vertical viewing angles and contrast ratios, check display units in stores yourself. Be sure to view the displays from several angles. If you're adding the panel as a second display, be sure to check its off-axis image quality.
- *Look for pivoting displays that enable you to rotate the display to match an upright page layout if you use your computer for text-editing or page layout.* This feature is supported by many LCD panels—particularly those that are 17" or larger—but the display performance in portrait mode is usually lower than in normal landscape mode, especially for rapid motion. If possible, test the display in portrait mode if you plan to use this mode frequently.

Video Adapter Types

A monitor requires a source of input. The signals that run to your monitor come from a video adapter inside or plugged into your computer.

The three ways computer systems connect to either CRT or LCD displays are as follows:

- *Add-on video cards*. This method requires the use of an AGP or a PCI expansion slot but provides the highest possible level of performance, the greatest amount of memory, and the largest choice of features.
- *Video-only chipset on motherboard*. Performance is generally less than with add-on video cards because older chipset designs are often used.
- *Motherboard chipset with integrated video*. This has the lowest cost of any video solution, but performance can also be very low, especially for 3D gaming or other graphics-intensive applications. Resolution and color-depth options are also more limited than those available with add-on video cards. However, new motherboard chipset designs from video-chipset makers such as NVIDIA (nForce series) and ATI (RADEON IGP) perform significantly better than other motherboard chipsets and often rival mid-range add-on video cards.

Most systems that use Baby-AT or ATX motherboards typically use add-on video cards, whereas the obsolete LPX and most current NLX and Micro-ATX motherboards typically use video chipsets on the motherboard. Many of the most recent low-cost computers built on the Micro-ATX, Flex-ATX, or NLX form factor use motherboard chipsets that integrate video, such as the Intel 810 series. Systems with integrated video (either with video chipsets or motherboard chipsets that include video) usually can be upgraded with an add-on video card, but some do not include an AGP slot, which is best suited for high-speed video today.

▶▶ See "Integrated Video/Motherboard Chipsets," p. 878.

▶▶ See "3D Chipsets," p. 903.

The term *video adapter* applies to either integrated or separate video circuitry.

Monitor Selection Criteria

Stores offer a dizzying variety of monitor choices, from the low-cost units bundled with computers to large-screen tubes that cost more than many systems. Because a monitor can account for a large part of the price of your computer system, you need to know what to look for when you shop for a monitor.

Important factors to consider include

- Viewable image size
- Resolution
- Dot pitch (CRTs)
- Image brightness and contrast (LCDs)
- Power management and safety certifications
- Vertical and horizontal frequencies
- Picture controls
- Environmental issues (lighting, size, weight)

This section helps you understand these issues so you can make a wise choice for your next display, regardless of the display technology you prefer.

The Right Size

CRT-based monitors come in various sizes ranging from 15" to 42" diagonal measure. The larger the monitor, the higher the price tag—after you get beyond 19" displays, the prices skyrocket. The most common CRT monitor sizes are 17", 19", and 21". These diagonal measurements, unfortunately, often represent not the size of the actual image the screen displays, but the size of the tube.

As a result, comparing one company's 17" CRT monitor to that of another might be unfair unless you actually measure the active screen area. The active screen area refers to the diagonal measure of the lighted area on the screen. In other words, if you are running Windows, the viewing area is the actual diagonal measure of the desktop.

This area can vary widely from monitor to monitor, so one company's 17" monitor can display a 16" image, and another company's 17" monitor can present a 15 1/2" image. Typically, you can expect to lose 1"–1 1/2" from the diagonal screen size to the actual active viewing area. Consult the monitor's packaging, advertising, or manufacturer's Web site for precise information for a given model. For example, ViewSonic lists the size of its G73f CRT monitor as the following: 17" (16.0" VIS [viewable image size]). I recommend that you concern yourself with the VIS, not the tube size, when you select a CRT monitor.

Note

Most CRTs currently on the market are 17" in size or larger; 17" has become the current standard, with 19" CRTs becoming common as prices drop below $500.

You can adjust many better-quality monitors to display a high-quality image that completely fills the tube from edge to edge. Less-expensive monitors can fill the screen also, but some of them do so only by pushing the monitor beyond its comfortable limits. The result is a distorted image that is worse than the monitor's smaller, properly adjusted picture.

In most cases today, the 17" CRT monitor is the best bargain in the industry. A 17" monitor is recommended for new systems, especially when running Windows, and is not much more expensive than a 15" display. I recommend a 17" monitor as the minimum you should consider for most normal applications. Displays of 19"–21" or larger are recommended for high-end systems, especially in situations where graphics applications are the major focus.

Note

One of the many reasons I don't recommend low-cost computers sold by major retail stores is because they often are bundled with 15" monitors. With 1,024×768 or higher resolutions becoming commonplace for both Internet and desktop applications, you need 17" CRTs or larger to comfortably support resolutions above 800×600. And, even if the system you are considering is bundled with a 17" display, the refresh rate can be too low for comfort at 1,024×768. If you buy the computer and monitor separately, you have a wider choice of displays and can get one of higher quality. You can also opt for an LCD display if space, rather than cost, is a major factor. Note that some vendors who make both computers and LCD displays, such as Sony, now bundle some of their computer models with LCD displays.

Larger monitors are particularly handy for applications such as CAD and desktop publishing, in which the smallest details must be clearly visible. With a 17" or larger display, you can see nearly an entire 8 1/2"×11" print page in 100% view; in other words, what you see onscreen virtually matches the

page that will be printed. Being able to see the entire page at its actual size can save you the trouble of printing several drafts of a document or project to get it right.

With the popularity of the Internet, monitor size and resolution become even more of an issue. Many Web pages are designed for 800×600 or higher resolutions. Whereas a 15" monitor can handle 800×600 fairly well, a 17" monitor set to 1,024×768 resolution enables you to comfortably view any Web site without eyestrain (if the monitor supports 75Hz or higher refresh rates) or excessive scrolling.

Note

Although many monitors smaller than 17" are physically capable of running at 1,024×768 and even higher resolutions, most people have trouble reading print at that size. A partial solution is to enable large icons in the Windows Display properties (right-click your desktop and select Properties). In Windows 98/Me/2000/XP, select Effects, Use Large Icons. Windows 95 doesn't have an option to enlarge only the icons; you can use the Settings tab to select Large Fonts, but some programs will not work properly with font sizes larger than the default Small Fonts setting.

Resolution

Resolution is the amount of detail a monitor can render. This quantity is expressed in the number of horizontal and vertical picture elements, or *pixels*, contained in the screen. The greater the number of pixels, the more detailed the images. The resolution required depends on the application. Character-based applications (such as DOS command-line programs) require little resolution, whereas graphics-intensive applications (such as desktop publishing and Windows software) require a great deal.

It's important to realize that CRTs are designed to handle a range of resolutions natively, but LCD panels (both desktop and notebook) are built to run a single native resolution and must scale to other choices. Older LCD panels handled scaling poorly, but even though current LCD panels perform scaling better, the best results with various resolutions are still found with CRTs.

As PC video technology developed, the screen resolutions video adapters support grew at a steady pace. The following list shows standard resolutions used in PC video adapters and the terms commonly used to describe them:

Resolution	Abbreviation	Standard Designation
640×480	VGA	Video Graphics Array
800×600	SVGA	Super VGA
1,024×768	XGA	eXtended Graphics Array
1,280×1,024	SXGA	Super XGA
1,600×1,200	UXGA	Ultra XGA

Today, the term *VGA* is still in common use as a reference to the standard 640×480 16-color display that most versions of the Windows operating systems use as their default; Windows XP, however, defaults to 800×600. The 15-pin connector to which you connect the CRT monitor on most video adapters is also often called a VGA plug. A 20-pin connector is used for DFP-compatible LCD display panels. A larger 24-pin connector is used on DVI-D displays, whereas DVI-I displays use a 29-pin version of the DVI-D connector (refer to Figure 15.4).

However, the terms SVGA, XGA, SXGA, and UXGA are used less often today to describe screen resolution. The industry typically describes screen resolutions simply by citing the number of pixels. Nearly all the video adapters sold today support 640×480, 800×600, 1,024×768, and 1,280×1,024 pixel resolutions at several color depths, and many support 1,600×1,200 and higher as well.

Because all CRT and most new and upcoming LCD displays can handle various resolutions, you have a choice. As you'll see later in this chapter, the combinations of resolution and color depth (number of colors onscreen) you can choose might be limited by how much RAM your graphics adapter has onboard or, if you have motherboard chipset-based video, how much system memory is allocated to your video function. If you switch to a larger display and you can't set the color depth you want to use, a new video card with more RAM is a desirable upgrade. Video cards once featured upgradeable memory, but this is no longer an option with current models.

Which resolution do you want for your display? Generally, the higher the resolution, the larger the display you will want. Why? Because Windows icons and text use a constant number of pixels, higher display resolutions make these screen elements a smaller part of the desktop onscreen. By using a larger display (17" or larger), you can use higher resolution settings and still have text and icons that are readable.

To understand this issue, you might want to try various resolutions on your system. As you change from 640×480 to 800×600 and 1,024×768, you'll notice several changes to the appearance of your screen.

At 640×480, text and onscreen icons are very large. Because the screen elements used for the Windows 9x/2000/Me desktop and software menus are at a fixed pixel width and height, you'll notice that they shrink in size onscreen as you change to the higher resolutions. You'll be able to see more of your document or Web page onscreen at the higher resolutions because each object requires less of the screen.

If you are operating at 640×480 resolution, for example, you should find a 15" monitor to be comfortable. At 1,024×768, you probably will find that the display of a 15" monitor is too small; therefore, you will probably prefer to use a larger one, such as a 17" monitor. The following list shows the smallest monitors I recommend to properly display the resolutions users typically select:

Resolution	Minimum Recommended CRT Monitor	Minimum Recommended LCD Panel
640×480	14"	15"
800×600	15"	15"
1,024×768	17"	15"
1,280×768	19"	17"
1,600×1,200	21"	18"

Although these are not necessarily the limits of a given monitor's capabilities, they are what I recommend. On small monitors set to high resolutions, characters, icons, and other information are too small for most users and can cause eyestrain. Low-cost CRT monitors and those bundled with many systems often produce blurry results when set to their maximum resolution.

Whereas CRTs can produce poor-quality results at very high resolutions, LCD displays are always crisp and perfectly focused by nature. Also, the dimensions advertised for the LCD screens represent the exact size of the viewable image, unlike most conventional CRT-based monitors. In addition, the LCD is so crisp that screens of a given size can easily handle resolutions that are higher than what would otherwise be acceptable on a CRT.

For example, many of the high-end notebook systems now use 14" or 15" LCD panels that feature 1,024×768 resolution. Although this resolution would be unacceptable on a 14" or 15" CRT display, it works well on the 14" or 15" LCD panel because of the crystal-clear image.

Dot Pitch (CRTs)

Another important specification that denotes the quality of a given CRT monitor is its dot pitch, which is controlled by the design of the shadow mask or aperture grille inside the CRT. A *shadow mask* is a metal plate built into the front area of the CRT, next to the phosphor layers. It has thousands of holes that are used to help focus the beam from each electron gun so that it illuminates only one correctly colored phosphor dot at a time. Because of the immense speed of screen rewriting (60–85 times per second), all dots appear to be illuminated at the same time. The mask prevents the electron gun from illuminating the wrong dots.

In a monochrome monitor, the picture element is a screen phosphor, but in a color monitor, the picture element is a phosphor triad—which is a group of three phosphor dots (red, green, and blue). Dot pitch, which applies only to color monitors, is the distance (in millimeters) between phosphor triads, measured from the center of a phosphor dot in a given triad to the same color phosphor dot in the next triad. Screens with a small dot pitch have a smaller space between the phosphor triads. As a result, the picture elements are closer together, producing a sharper picture onscreen. Conversely, screens with a large dot pitch tend to produce images that are less clear. Figure 15.5 illustrates dot pitch.

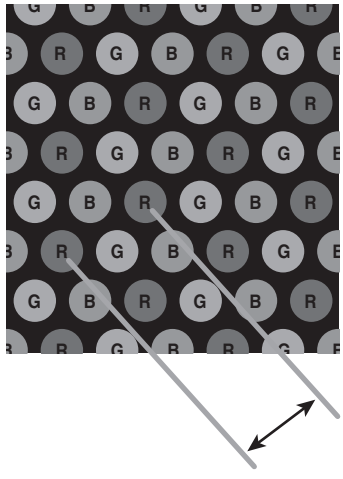

Figure 15.5 Dot pitch is the distance between each group (triad) of red, green, and blue (RGB) phosphors. A smaller dot pitch helps produce sharper, clearer images.

Note

Dot pitch is not an issue with LCD portable or desktop display panels because of their designs, which use transistors rather than phosphor triads.

The original IBM PC color monitor had a dot pitch of .43mm, which is considered to be poor by almost any standard. Smaller pitch values indicate sharper images. Most monitors have a dot pitch between .25mm and .30mm, with state-of-the-art monitors at the lower end of the scale. To avoid grainy images, look for a dot pitch of .26mm or smaller. Be wary of monitors with anything larger than a .28mm dot pitch; they lack clarity for fine text and graphics. Although you can save money by buying monitors with smaller tubes or a higher dot pitch, the trade-off isn't worth it.

Monitors based on Sony's Trinitron picture tubes and Mitsubishi's DiamondTron picture tubes use an aperture grille, which uses vertical strips (rather than a shadow mask) to separate red, green, and blue phosphors. This produces a brighter picture, although the stabilizing wires shown in Figure 15.6 are visible on close examination. Monitors using an aperture grille–type picture tube use a stripe pitch measurement instead of dot pitch. An aperture grille monitor stripe pitch of .25mm is comparable to a .27mm dot pitch on a conventional monitor.

Some of NEC's monitors use a variation on the aperture grille called the slotted mask, which is brighter than standard shadow-mask monitors and more mechanically stable than aperture grille–based monitors (see Figure 15.6).

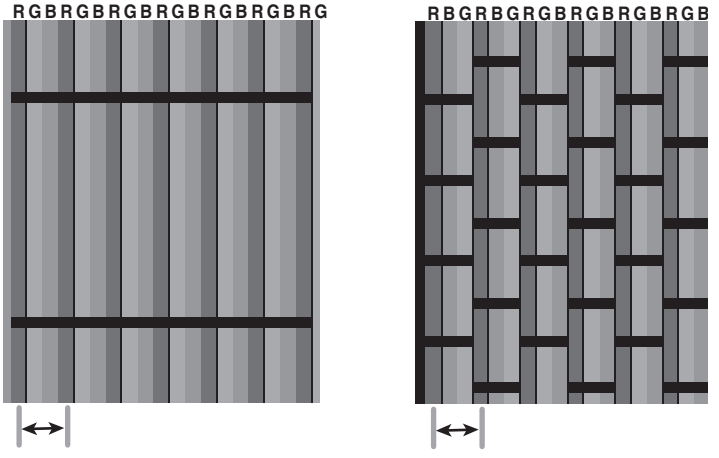

Figure 15.6 Aperture-grille picture tubes (left) have their phosphors arranged in vertical stripes with one or two reinforcing wires, depending on CRT size. NEC's CromaClear slotted mask picture tube design (right) provides many of the benefits of both the shadow-mask and aperture-grille designs.

The dot pitch or stripe pitch measurement is one of the most important specifications of any monitor, but it is not the only specification. You might find the image on a monitor with a slightly higher dot pitch superior to that of a monitor with a lower dot pitch. There is no substitute for actually looking at images and text on the monitors you're considering purchasing.

Image Brightness and Contrast (LCD Panels)

As previously mentioned, dot pitch is not a factor in deciding which LCD panel to purchase. Although it's a consideration that applies to both LCDs and CRTs, the brightness of a display is especially important in judging the quality of an LCD panel.

Although a dim CRT display is almost certainly a sign of either improper brightness control or a dying monitor, brightness in LCD panels can vary a great deal from one model to another. Brightness for LCD panels is measured in candelas per square meter, which for some reason is referred to as a *nit*. Typical ratings for analog and digital display panels range from under 100 to as much as 250 nits. A good combination is a high nit rating (150 or above) and a high contrast rating.

Interlaced Versus Noninterlaced

Monitors and video adapters can support interlaced or noninterlaced resolution. In *noninterlaced* (conventional) mode, the electron beam sweeps the screen in lines from top to bottom, one line after the other, completing the screen in one pass. In *interlaced* mode, the electron beam also sweeps the screen from top to bottom, but it does so in two passes—sweeping the odd lines first and the even lines second. Each pass takes half the time of a full pass in noninterlaced mode. Early high-resolution monitors, such as the IBM 8514/A, used interlacing to reach their maximum resolutions, but all recent and current high-resolution (1,024×768 and higher) monitors are noninterlaced, avoiding the slow screen response and flicker caused by interlacing.

For more information about interlaced displays, see "Interlaced Versus Noninterlaced" in Chapter 15 of *Upgrading and Repairing PCs, 12th Edition*, included in electronic form on the DVD-ROM accompanying this book.

Energy and Safety

Monitors, like virtually all power-consuming computer devices, have been designed to save energy for a number of years. Virtually all monitors sold in recent years have earned the Environmental Protection Agency's Energy Star logo by reducing their current draw to 30 watts or less when idle. Power-management features in the monitor, as well as controls provided in the system BIOS and in the latest versions of Windows, help monitors and other types of computing devices use less power.

▶▶ For more information about power management, see Chapter 21, "Power Supply and Chassis/Case," p. 1155.

Power Management

One of the first energy-saving standards for monitors was VESA's Display Power-Management Signaling (DPMS) spec, which defined the signals a computer sends to a monitor to indicate idle times. The computer or video card decides when to send these signals.

In Windows 9x/Me/2000/XP, you must enable this feature if you want to use it because it's turned off by default. To enable it in Windows 9x/Me, open the Display properties in the Control Panel, switch to the Screen Saver tab, and make sure the Energy Star low-power settings and Monitor Shutdown settings are checked. You can adjust how long the system remains idle before the monitor picture is blanked or the monitor shuts down completely. Use the Power icon in Windows 2000/XP to set power management for the monitor and other peripherals. You can also access power management by selecting the Screen Saver tab on the Display properties sheet and clicking the Power button.

Intel and Microsoft jointly developed the Advanced Power Management (APM) specification, which defines a BIOS-based interface between hardware that is capable of power-management functions and an operating system that implements power-management policies. In short, this means you can configure an OS such as Windows 9x to switch your monitor into a low-power mode after an interval of nonuse and even to shut it off entirely. For these actions to occur, however, the monitor, system BIOS, and operating system must all support the APM standard.

With Windows 98, Windows Me, Windows 2000, and Windows XP, Microsoft introduced a more comprehensive power-management method called Advanced Configuration and Power Interface (ACPI). ACPI also works with displays, hard drives, and other devices supported by APM and allows the computer to automatically turn peripherals, such as CD-ROMs, network cards, hard disk drives, and printers, on and off. It also enables the computer to turn consumer devices connected to the PC, such as VCRs, televisions, telephones, and stereos, on and off.

Although APM compatibility has been standard in common BIOSes for several years, a number of computers from major manufacturers required BIOS upgrades to add ACPI support when Windows 98 was introduced.

Note

ACPI support is installed on Windows 98, Windows Me, Windows 2000, and Windows XP computers only if an ACPI-compliant BIOS is present when either version of Windows is first installed. If an ACPI-compliant BIOS is installed after the initial Windows installation, it is ignored. Fortunately, both versions of Windows still support APM as well. See Microsoft's FAQ for ACPI on the Microsoft Web site.

Use Table 15.1 to select the most appropriate DPMS power-management setting(s) for your needs. Most recent systems enable you to select separate values for standby (which saves minimal amounts of power) and for monitor power-down (which saves more power but requires the user to wait several seconds for the monitor to power back up).

Table 15.1 Display Power Management Signaling

State	Horizontal	Vertical	Video	Power Savings	Recovery Time
On	Pulses	Pulses	Active	None	n/a
Stand-By	No Pulses	Pulses	Blanked	Minimal	Short
Suspend	Pulses	No Pulses	Blanked	Substantial	Longer
Off	No Pulses	No Pulses	Blanked	Maximum	System Dependent

Virtually all monitors with power management features meet the requirements of the United States EPA's Energy Star labeling program, which requires that monitor power usage be reduced to 15 watts or less in standby mode. However, some current monitors also comply with the far more stringent Energy 2000 (E2000) standard developed in Switzerland. E2000 requires that monitors use less than 5 watts when in standby mode.

Emissions

Another trend in green monitor design is to minimize the user's exposure to potentially harmful electromagnetic fields. Several medical studies indicate that these electromagnetic emissions can cause health problems, such as miscarriages, birth defects, and cancer. The risk might be low, but if you spend a third of your day (or more) in front of a computer monitor, that risk is increased.

The concern is that VLF (very low frequency) and ELF (extremely low frequency) emissions might affect the body. These two emissions come in two forms: electric and magnetic. Some research indicates that ELF magnetic emissions are more threatening than VLF emissions because they interact with the natural electric activity of body cells. Monitors are not the only culprits; significant ELF emissions also come from electric blankets and power lines.

Note

ELF and VLF are a form of electromagnetic radiation; they consist of radio frequencies below those used for normal radio broadcasting.

The standards shown in Table 15.2 have been established to regulate emissions and other aspects of monitor operations. Even though these standards originated with Swedish organizations, they are recognized and supported throughout the world.

Table 15.2 Monitor Emissions Standards

Standard Name	Established by	Date Established	Regulates	Notes
MPR I	SWEDAC[1]	1987	Monitor emissions	Replaced by MPR II.
MPR II	SWEDAC[1]	1990	Monitor emissions	Added maximums for ELF and VLF; minimum standard in recent monitors.
TCO[2]	TCO[2]	1992	Tighter monitor emissions limits than MPR-II; power management	TCO 95 and TCO 99 add other classes of devices to the TCO standard.

1. The Swedish Board for Accreditation and Conformity Assessment

2. Swedish abbreviation for the Swedish Confederation of Professional Employees

Today, virtually all monitors on the market support TCO standards.

If you aren't using a low-emission monitor yet, you can take other steps to protect yourself. The most important is to stay at arm's length (about 28 inches) from the front of your monitor. When you move a couple of feet away, ELF magnetic emission levels usually drop to those of a typical office with fluorescent lights. Likewise, monitor emissions are weakest at the front of a monitor, so stay at least 3 feet from the sides and backs of nearby monitors and 5 feet from any photocopiers, which are also strong sources of ELF.

Electromagnetic emissions should not be your only concern; you also should be concerned about screen glare. In fact, some of the antiglare panels that fit in front of a monitor screen not only reduce eyestrain, but also cut ELF and VLF emissions.

Note that because plasma and LCD displays don't use electron guns or magnets, they don't produce ELF emissions.

Frequencies

One essential buying decision is to choose a monitor that works with your selected video adapter. Today, virtually all monitors are multiple-frequency (also called multiscanning and multifrequency) units that accommodate a range of standards, including those that are not yet standardized. However, big differences exist in how well various monitors cope with various video adapters.

Tip

High-quality monitors retain their value longer than most other computer components. Although it's common for a newer, faster processor to come out right after you have purchased your computer or to find the same model with a bigger hard disk for the same money, a good quality monitor should outlast your computer. If you purchase a unit with the expectation that your own personal requirements will grow over the years, you might be able to save money on your next system by reusing your old monitor.

Some useful features include

- Front-mounted digital controls that can memorize screen settings
- Onscreen programmability to enable you to precisely set desired values for screen size and position
- Self-test mode, which displays a picture even when your monitor is not receiving a signal from the computer

With multiple-frequency CRT monitors, you must match the range of horizontal and vertical frequencies the monitor accepts with those generated by your video adapter. The wider the range of signals, the more expensive—and more versatile—the monitor. Your video adapter's vertical and horizontal frequencies must fall within the ranges your monitor supports. The vertical frequency (or refresh/frame rate) determines the stability of your image (the higher the vertical frequency, the better). Typical vertical frequencies range from 50Hz to 160Hz, but multiple-frequency monitors support different vertical frequencies at different resolutions. You might find that a bargain monitor has a respectable 100Hz vertical frequency at 640×480 but drops to a less desirable 60Hz at 1,024×768. The horizontal frequency (or line rate) typically ranges from 31.5KHz to 90KHz or more. By default, most video adapters use a 60Hz default vertical scan frequency to avoid monitor damage.

Although LCD monitors use lower vertical frequencies than CRTs, they avoid problems with screen flicker because of their design. Because they use transistors to activate all the pixels in the image at once, as opposed to a scanning electron beam that must work its way from the top to the bottom of the screen to create an image, LCD panels never flicker.

Refresh Rates (Vertical Scan Frequency)

The *refresh rate* (also called the vertical scan frequency) is the rate at which the screen display is rewritten. This is measured in hertz. A refresh rate of 72Hz means that the screen is refreshed 72 times per second. A refresh rate that is too low causes CRT screens to flicker, contributing to eyestrain. The higher the refresh rate, the better for your eyes and your comfort during long sessions at the computer.

A *flicker-free refresh rate* is a refresh rate high enough to prevent you from seeing any flicker. The flicker-free refresh rate varies with the resolution of your monitor setting (higher resolutions require higher refresh rates) and must be matched by both your monitor and display card. Because a refresh rate that is too high can slow down your video display, use the lowest refresh rate that is comfortable for you.

One important factor to consider when purchasing a CRT monitor is the refresh rate, especially if you are planning to use the monitor at 1,024×768 or higher resolutions. Low-cost monitors sometimes have refresh rates that are too low to achieve flicker-free performance for most users and thus can lead to eyestrain.

Table 15.3 compares two typical 17" CRT monitors and a typical mid-range graphics card.

Note the differences in the refresh rates supported by the ATI RADEON 7500 (based on the popular ATI RADEON 7500 GPU [graphics processing unit] chip) and two 17" CRT monitors from ViewSonic: the A70 and PF77.

The A70 sells for around $220, and the PF77 sells for about $360. The PF77 offers flicker-free refresh rates at higher resolutions than the cheaper A70.

Although the ATI RADEON 7500 video card supports higher refresh rates than either monitor, these rates can't be used safely. Use of video adapter refresh rates in excess of the monitor's maximum refresh rate can damage the monitor!

Table 15.3 Refresh Rates Comparison

Resolution	ATI RADEON 7500 Video Card Vertical Refresh	ViewSonic A70 (17") Monitor Vertical Refresh (Maximum)	ViewSonic PF77 (17") Monitor Vertical Refresh (Maximum)
1,024×768	60Hz–200Hz[1]	87Hz[1]	118Hz[1]
1,280×1,024	60Hz–160Hz[1]	66Hz	89Hz[1]
1,600×1,200	60Hz–120Hz[1]	Not supported	77Hz[1]

1. Rates above 72Hz will be flicker-free for many users; the VESA standard for flicker-free refresh is 85Hz or above.

To determine a monitor's refresh rates for the resolutions you're planning to use, check out the monitor manufacturer's Web site.

During installation, Windows 2000, Windows 98, Windows 95B (OSR 2.x), Windows Me, and Windows XP support Plug and Play (PnP) monitor configuration if both the monitor and video adapter support the Data Display Channel (DDC) feature. When DDC communication is available, the monitor can send signals to the operating system that indicate which refresh rates it supports, as well as other display information; this data is reflected by the Display Properties sheet for that monitor.

Monitors that don't support PnP configuration via DDC can be configured with an .INF (information) file, just as with other Windows-compatible devices. This might be supplied with a setup disk or can be downloaded from the monitor vendor's Web site.

Note

Because monitors are redrawing the screen many times per second, the change in a noninterlaced screen display is virtually invisible to the naked eye, but it is very obvious when computer screens are photographed, filmed, or videotaped. Because these cameras aren't synchronized to the monitor's refresh cycle, it's inevitable that the photo, film, or videotape will show the refresh in progress as a line across the picture.

If you need to capture moving images from a monitor to videotape, use a video card with a TV-out option to send your picture to a VCR.

In my experience, a 60Hz vertical scan frequency (frame rate) is the minimum anybody should use, and even at this frequency, most people notice a flicker. Especially on a larger display, onscreen flicker can cause eyestrain and fatigue. If you can select a frame rate (vertical scan frequency) of 72Hz or higher, most people are not able to discern any flicker. Most modern mid-range or better displays easily handle vertical frequencies up to 85Hz or more at resolutions up to 1,024×768. This greatly reduces the flicker a user sees. However, note that increasing the frame rate, although it improves the quality of the image, can also slow down the video hardware because it now needs to display each image more times per second. In general, I recommend that you set the lowest frame rate you find comfortable. To adjust the video card's refresh rate with Windows 9x/Me/2000/XP, use the Display icon in Control Panel.

Depending on your flavor of Windows, the refresh rates supported by the video card will appear on one of the Display tabs. Optimal is the default setting, but this really is a "safe" setting for any monitor. Select a refresh rate of at least 72Hz or higher to reduce or eliminate flicker. Click Apply for the new setting to take effect. If you choose a refresh rate other than Optimal, you'll see a warning about

possible monitor damage. This is a warning you should take seriously, especially if you don't have detailed information about your monitor available. You can literally smoke a monitor if you try to use a refresh rate higher than the monitor is designed to accept. Before you try using a custom refresh rate, do the following:

- Make sure Windows has correctly identified your monitor as either a Plug and Play monitor or by brand and model.
- Check the manual supplied with the monitor (or download the statistics) to determine which refresh rates are supported at a given resolution. As in the example listed earlier, low-cost monitors often don't support high refresh rates at higher resolutions.

Click OK to try the new setting. The screen changes to show the new refresh rate. If the screen display looks scrambled, wait a few moments and the screen will be restored to the previous value; you'll see a dialog box asking whether you want to keep the new setting. If the display was acceptable, click Yes; otherwise, click No to restore your display. If the screen is scrambled and you can't see your mouse pointer, just press the Enter key on your keyboard because No is the default answer. With some older video drivers, this refresh rate dialog box is not available. Get an updated video driver, or check with the video card vendor for a separate utility program that sets the refresh rate for you.

If you have a scrambled display with a high refresh rate, but you think the monitor should be capable of handling the refresh rate you chose, you might not have the correct monitor selected. To check your Windows 9x/Me/2000/XP monitor selection, check the Display Properties dialog box. If your monitor is listed as Standard VGA, Super VGA, or Default Monitor, Windows is using a generic driver that will work with a wide variety of monitors. However, this generic driver doesn't support refresh rates above 75Hz because some monitors could be damaged by excessive refresh rates.

In some cases, you might need to manually select the correct monitor brand and model in the Windows Display Properties dialog box. If you don't find your brand and model of monitor listed, check with your monitor vendor for a driver specific for your model. After you install it, see whether your monitor will safely support a higher refresh rate.

Horizontal Frequency

Different video resolutions use different horizontal frequencies. For example, the standard VGA resolution of 640×480 requires a horizontal resolution of 31.5KHz, whereas the 800×600 resolution requires a vertical frequency of at least 72Hz and a horizontal frequency of at least 48KHz. The 1,024×768 image requires a vertical frequency of 60Hz and a horizontal frequency of 58KHz, and the 1,280×1,024 resolution requires a vertical frequency of 60Hz and a horizontal frequency of 64KHz. If the vertical frequency increases to 75Hz at 1,280×1,024, the horizontal frequency must be 80KHz. For a super-crisp display, look for available vertical frequencies of 75Hz or higher and horizontal frequencies of up to 90KHz or more. My favorite 17" NEC monitor supports vertical resolutions of up to 75Hz at 1,600×1,200 pixels, 117Hz at 1,024×768, and 160Hz at 640×480!

Virtually all the analog monitors on the market today are, to one extent or another, multiple-frequency. Because literally hundreds of manufacturers produce thousands of monitor models, it is impractical to discuss the technical aspects of each monitor model in detail. Suffice it to say that before investing in a monitor, you should check the technical specifications to ensure that the monitor meets your needs. If you are looking for a place to start, check out some of the magazines that periodically feature reviews of monitors. If you can't wait for a magazine review, investigate monitors at the Web sites run by any of the following vendors: IBM, Sony, NEC-Mitsubishi, and ViewSonic. Each of these manufacturers creates monitors that set the standards by which other monitors can be judged. Although you typically pay a bit more for these manufacturers' monitors, they offer a known, high level of quality and compatibility, as well as service and support. Note that most monitor

companies sell several lines of monitors, varying by refresh rates, CRT type, antiglare coatings, energy efficiency, and warranties. For best results at resolutions of 1,024×768 and above, avoid the lowest-cost 17" monitors because these models tend to produce fuzzy onscreen displays with low refresh rates.

Controls

Most of the newer CRT monitors and LCD panels use digital controls instead of analog controls. This has nothing to do with the signals the monitor receives from the computer, but only the controls (or lack of them) on the front panel that enable you to adjust the display. Monitors with digital controls have a built-in menu system that enables you to set parameters such as brightness (which adjusts the black level of the display), contrast (which adjusts the luminance of the display), screen size, vertical and horizontal shifts, color, phase, and focus. A button brings the menu up onscreen, and you use controls to make menu selections and vary the settings. When you complete your adjustments, the monitor saves the settings in nonvolatile RAM (NVRAM) located inside the monitor. This type of memory provides permanent storage for the settings with no battery or other power source. You can unplug the monitor without losing your settings, and you can alter them at any time in the future. Digital controls provide a much higher level of control over the monitor and are highly recommended.

Tip

Digital video engineer Charles Poynton's notes on adjusting brightness and contrast controls provide an excellent tutorial on the use of these often misunderstood monitor adjustments. Find them online at `www.inforamp.net/~poynton/notes/brightness_and_contrast/`.

Digital controls make adjusting CRT monitors suffering from any of the geometry errors shown in Figure 15.7 easy. Before making these adjustments, be sure the vertical and horizontal size and position are correct.

Tip

Get a monitor with positioning and image controls that are easy to reach, preferably on the front of the case. Look for more than just basic contrast and brightness controls; a good monitor should enable you to adjust the width and height of your screen images and the placement of the image on the screen. The monitor should also be equipped with a tilt-swivel stand so you can adjust the monitor to the best angle for your use.

Although LCD panels aren't affected by geometry errors as CRT monitors can be, they can have their own set of image-quality problems, especially if they use the typical 15-pin analog VGA video connector. Pixel jitter and pixel swim (in which adjacent pixels turn on and off) are relatively common problems that occur when using an LCD monitor connected to your PC with an analog VGA connector.

Environment

One factor you might not consider when shopping for a monitor is the size and strength of the desk on which you intend to put it. Although many 17" CRT monitors use less desk space than before, reducing the 18"–24" depth used by older models to a more reasonable 16"–17" depth, these monitors are still relatively heavy at around 35–40 lbs. 21" and larger monitors can be truly huge, weighing in at 60 lbs. or more! Some of the rickety computer stands and mechanical arms used to keep monitors off the desktop might not be capable of safely holding or supporting a large unit. Check the weight rating of the computer stand or support arm you're planning to use before you put a CRT monitor on it. It's tragic to save a few dollars on these accessories, only to watch them crumple under the weight of a large monitor and wipe out your monitor investment.

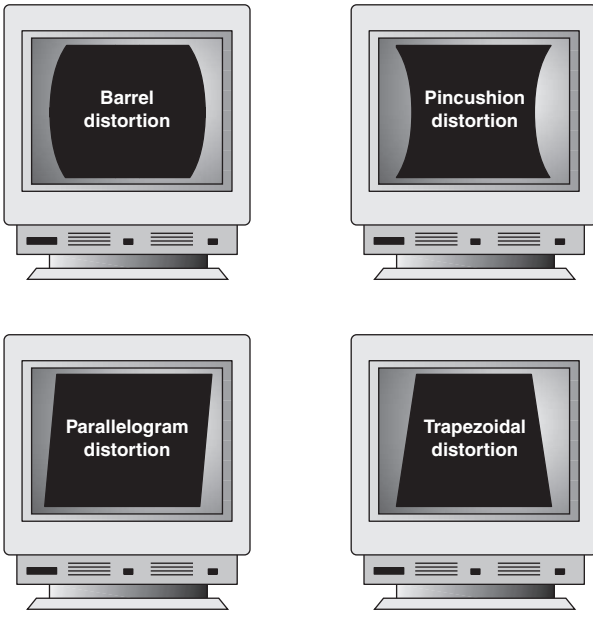

Figure 15.7 Typical geometry errors in CRT monitors; these can be corrected on most models that have digital picture controls.

Tip

If you are using a relatively narrow computer table but don't want to use an LCD panel, look for a monitor that uses the so-called short-neck or short-depth CRTs. These short-neck CRTs are used in many recent 17" and 19" models and allow the monitor to take up less space front to back; this often is referred to as a smaller footprint. Some 17" short-neck models use no more front-to-back space than typical 15" models and weigh less. ViewSonic's GS773 short-depth 17" monitor is only 15.2" deep and weighs only 35 lbs.

Another important consideration is the lighting in the room in which you will use the monitor. The appearance of a CRT display in the fluorescent lighting of an office is markedly different from that in your home. The presence or absence of sunlight in the room also makes a big difference. Office lighting and sunlight can produce glare that becomes incredibly annoying when you are forced to stare at it for hours on end. You can reduce onscreen glare by choosing monitors equipped with flat-square or other flat CRT technologies or LCD panels and antiglare coatings. You can retrofit aftermarket filters to monitors that lack these features to help reduce glare.

Tip

If you are extremely short of space or have relatively light-duty computer furniture, consider the newest 15" LCD display panels, which weigh only 10 lbs. or so and feature a much narrower front-to-back footprint than 17" CRTs.

Testing a Display

Unlike most of the other peripherals you can connect to your computer, you can't really tell whether a monitor suits you by examining its technical specifications. Price might not be a reliable indicator

either. Testing monitors is a highly subjective process, and it is best to "kick the tires" of a few at a dealer showroom or in the privacy of your home or office (if the dealer has a liberal return policy).

Testing should also not be simply a matter of looking at whatever happens to be displayed on the monitor at the time. Many computer stores display movies, scenic photos, or other flashy graphics that are all but useless for a serious evaluation and comparison. If possible, you should look at the same images on each monitor you try and compare the manner in which they perform a specific series of tasks.

Before running the tests listed here, set your display to the highest resolution and refresh rate allowed by your combination of display and graphics card.

One good series of tasks is as follows:

- *Draw a perfect circle with a graphics program.* If the displayed result is an oval, not a circle, this monitor will not serve you well with graphics or design software.
- *Using a word processor, type some words in 8- or 10-point type (1 point equals 1/72").* If the words are fuzzy or the black characters are fringed with color, select another monitor.
- *Display a screen with as much white space as possible and look for areas of color variance.* This can indicate a problem with only that individual unit or its location, but if you see it on more than one monitor of the same make, it might indicate a manufacturing problem; it could also indicate problems with the signal coming from the graphics card. Move the monitor to another system equipped with a different graphics card model and retry this test to see for certain whether it's the monitor or the video card.
- *Display the Microsoft Windows desktop to check for uniform focus and brightness.* Are the corner icons as sharp as the rest of the screen? Are the lines in the title bar curved or wavy? Monitors usually are sharply focused at the center, but seriously blurred corners indicate a poor design. Bowed lines can be the result of a poor video adapter, so don't dismiss a monitor that shows those lines without using another adapter to double-check the effect. Adjust the brightness up and down to see whether the image blooms or swells, which indicates the monitor is likely to lose focus at high brightness levels. You can also use diagnostics that come with the graphics card or third-party system diagnostics programs to perform these tests.
- *With LCD displays in particular, change to a lower resolution from the panel's native resolution using the Microsoft Windows Display properties settings.* Because LCD panels have only one native resolution, the display must use scaling to handle other resolutions full-screen. If you are a Web designer, are a gamer, or must capture screens at a particular resolution, this test will show you whether the LCD panel produces acceptable display quality at resolutions other than normal. You can also use this test on a CRT, but CRTs, unlike LCD panels, are designed to handle a wide variety of resolutions.
- *A good monitor is calibrated so that rays of red, green, and blue light hit their targets (individual phosphor dots) precisely.* If they don't, you have bad convergence. This is apparent when edges of lines appear to illuminate with a specific color. If you have good convergence, the colors are crisp, clear, and true, provided there isn't a predominant tint in the phosphor.
- *If the monitor has built-in diagnostics (a recommended feature), try them as well to test the display independently of the graphics card and system to which it's attached.*

Maintaining Your Monitor

Because a good 17" or larger monitor can be used for several years on more than one computer, proper care is essential to extend its life to the fullest extent.

Use the following guidelines for proper care of your monitors:

- *Although phosphor burn (in which an image left onscreen eventually leaves a permanent shadow onscreen) is next-to-impossible with VGA-type displays—unlike the old TTL displays—screensavers are still useful for casual security.* You can password-protect your system with both the standard Windows screensaver and third-party programs (although a determined snoop can easily thwart screensaver password protection). Windows includes several screensavers that can be enabled via the Display Control Panel. A bevy of free and inexpensive screensavers is available for download from the Internet. Keep in mind, though, that add-on screensavers can cause crashes and lockups if they're poorly written or out-of-date. Use screensavers written for your particular operating system version to minimize problems.
- *To prevent premature failure of the monitor's power supply, use the power-management feature of the Display Properties or Power (Management) sheet to put the monitor into a low-power standby mode after a reasonable period of inactivity (10–15 minutes) and to turn it off after about 60 minutes.* Using the power management feature is far better than using the on/off switch when you are away from the computer for brief periods. Turn off the monitor only at the end of your computing "day."

  How can you tell whether the monitor is really off or in standby mode? Look at the power LCD on the front of the monitor. A monitor that's in standby mode usually has a blinking green or solid amber LCD in place of the solid green LCD displayed when it's running in normal mode. Because monitors in standby mode still consume some power, they should be shut off at the end of the computing day.

  If the monitor will not go into standby when the PC isn't sending signals to it, make sure the monitor is properly defined in Windows' Display Properties sheet. In addition, the Energy Star check box should be selected for any monitor that supports power management, unless the monitor should be left on at all times (such as when used in a retail kiosk or self-standing display).
- *Make sure the monitor has adequate ventilation along the sides, rear, and top.* Because monitors use passive cooling, a lack of adequate airflow caused by piling keyboards, folders, books, or other office debris on top of the monitor will cause it to overheat and considerably shorten its life. If you're looking at a monitor with a partly melted grille on the top of the case, you're looking at a victim of poor cooling. If you need to use a monitor in an area with poor airflow, use an LCD panel instead of a CRT because LCDs run much cooler than CRTs.
- *The monitor screen and case should be kept clean.* Turn off the power, spray a cleaner such as Endust for Electronics onto a soft cloth (never directly onto the monitor!), and wipe the screen and the case gently.
- *If your CRT monitor has a degaussing button or feature, use it periodically to remove stray magnetic signals.* Keep in mind that CRTs have powerful magnets around the picture tube, so keep magnetic media away from them.

Video Display Adapters

A video adapter provides the interface between your computer and your monitor and transmits the signals that appear as images on the display. Throughout the history of the PC, there have been a succession of standards for video display characteristics that represent a steady increase in screen resolution and color depth. The following list of standards can serve as an abbreviated history of PC video-display technology:

MDA (Monochrome Display Adapter)
HGC (Hercules Graphics Card)
CGA (Color Graphics Adapter)
EGA (Enhanced Graphics Adapter)
VGA (Video Graphics Array)
SVGA (Super VGA)
XGA (Extended Graphics Array)
UVGA (Ultra VGA)
SXGA (Super XGA)
UXGA (Ultra XGA)

IBM pioneered most of these standards, but other manufacturers of compatible PCs adopted them as well. Today, IBM is no longer the industry leader it once was (and hasn't been for some time), and many of these standards are obsolete. Those that aren't obsolete seldom are referred to by these names anymore. The sole exception to this is *VGA*, which is a term that is still used to refer to a baseline graphics display capability supported by virtually every video adapter on the market today.

When you shop for a video adapter today, you are more likely to see specific references to the screen resolutions and color depths that the device supports than a list of standards such as VGA, SVGA, XGA, and UVGA. However, reading about these standards gives you a good idea of how video-display technology developed over the years and prepares you for any close encounters you might have with legacy equipment from the dark ages.

Today's VGA and later video adapters can also display most older color graphics software written for CGA, EGA, and most other obsolete graphics standards. This enables you to use older graphics software (such as games and educational programs) on your current system. Although not a concern for most users, some older programs wrote directly to hardware registers that are no longer found on current video cards.

Obsolete Display Adapters

Although many types of display systems were at one time considered to be industry standards, few of these are viable standards for today's hardware and software.

Note

If you are interested in reading more about MDA, HGC, CGA, EGA, or MCGA display adapters, see Chapter 8 of *Upgrading and Repairing PCs, 10th Anniversary Edition*, included on the DVD with this book.

Current Display Adapters

When IBM introduced the PS/2 systems on April 2, 1987, it also introduced the VGA display. On that day, in fact, IBM also introduced the lower-resolution MCGA and higher-resolution 8514 adapters. The MCGA and 8514 adapters did not become popular standards like the VGA did, and both were discontinued.

All current display adapters that connect to the 15-pin VGA analog connector or the DVI analog/digital connector are based on the VGA standard.

Digital Versus Analog Signals

Unlike earlier video standards, which are digital, the VGA is an analog system. Why have displays gone from digital to analog when most other electronic systems have gone digital? Compact disc players (digital) have replaced most turntables (analog), mini DV camcorders are replacing 8MM and VHS-based analog camcorders, and TiVo and UltimateTV digital video recorders are performing time-shifting in place of analog VCRs for many users. With a digital television set, you can watch several channels on a single screen by splitting the screen or placing a picture within another picture.

Most personal computer displays introduced before the PS/2 are digital. This type of display generates different colors by firing the RGB electron beams in on-or-off mode, which allows for the display of up to eight colors (2^3). In the IBM displays and adapters, another signal doubles the number of color combinations from 8 to 16 by displaying each color at one of two intensity levels. This digital display is easy to manufacture and offers simplicity with consistent color combinations from system to system. The real drawback of the older digital displays such as CGA and EGA is the limited number of possible colors.

In the PS/2 systems, IBM went to an analog display circuit. Analog displays work like the digital displays that use RGB electron beams to construct various colors, but each color in the analog display system can be displayed at varying levels of intensity—64 levels, in the case of the VGA. This versatility provides 262,144 possible colors (64^3), of which 256 could be simultaneously displayed. For realistic computer graphics, color depth is often more important than high resolution because the human eye perceives a picture that has more colors as being more realistic. IBM moved to analog graphics to enhance the color capabilities of its systems.

Video Graphics Array

PS/2 systems incorporated the primary display adapter circuitry onto the motherboard, and both IBM and third-party companies introduced separate VGA cards to enable other types of systems to enjoy the advantages of VGA.

Although the IBM MicroChannel (MCA) computers, such as the PS/2 Model 50 and above, introduced VGA, it's impossible today to find a brand-new replacement for VGA that fits into the obsolete MCA-bus systems. However, surplus and used third-party cards might be available if you look hard enough.

The VGA BIOS is the control software residing in the system ROM for controlling VGA circuits. With the BIOS, software can initiate commands and functions without having to manipulate the VGA directly. Programs become somewhat hardware independent and can call a consistent set of commands and functions built into the system's ROM-control software.

◀◀ See "Video Adapter BIOS," p. 481.

Other implementations of the VGA differ in their hardware but respond to the same BIOS calls and functions. New features are added as a superset of the existing functions, and VGA remains compatible with the graphics and text BIOS functions built into the PC systems from the beginning. The VGA can run almost any software that originally was written for the CGA or EGA, unless it was written to directly access the hardware registers of these cards.

A standard VGA card displays up to 256 colors onscreen, from a palette of 262,144 (256KB) colors; when used in the 640×480 graphics or 720×400 text mode, 16 colors at a time can be displayed. Because the VGA outputs an analog signal, you must have a monitor that accepts an analog input.

VGA displays originally came not only in color, but also in monochrome VGA models, which use color summing. With color summing, 64 gray shades are displayed instead of colors. The summing routine is initiated if the BIOS detects a monochrome display when the system boots. This routine uses an algorithm that takes the desired color and rewrites the formula to involve all three color guns, producing varying intensities of gray. Users who preferred a monochrome display, therefore, could execute color-based applications.

Note

For a listing of the VGA display modes supported by the original IBM VGA card (and thus all subsequent VGA-type cards), see "VGA Display Modes" in Chapter 15 of *Upgrading and Repairing PCs, 12th Edition*, available in electronic form on the DVD-ROM supplied with this book.

Even the least-expensive video adapters on the market today can work with modes well beyond the VGA standard. VGA, at its 16-color, 640×480 graphics resolution, has come to be the baseline for PC graphical display configurations. VGA is accepted as the least common denominator for all Windows systems and must be supported by the video adapters in all systems running Windows. The installation programs of all Windows versions use these VGA settings as their default video configuration. In addition to VGA, virtually all adapters support a range of higher screen resolutions and color depths, depending on the capabilities of the hardware. If a Windows 9x/Me or Windows XP/2000 system must be started in Safe Mode because of a startup problem, the system defaults to VGA in the 640×480, 16-color mode. Windows 2000 and Windows XP also offer a VGA Mode startup that also uses this mode (Windows XP uses 800×600 resolution) but doesn't slow down the rest of the computer the way Safe Mode (which replaces 32-bit drivers with BIOS services) does.

IBM introduced higher-resolution versions of VGA called XGA and XGA-2 in the early 1990s, but most of the development of VGA standards has come from the third-party video card industry and its trade group, the Video Electronic Standards Association (VESA).

Note

If you are interested in reading more about the XGA and XGA-2 display adapters, see "XGA and XGA-2" in Chapter 8 of *Upgrading and Repairing PCs, 10th Anniversary Edition*, included on the DVD with this book.

Super VGA

When IBM's XGA and 8514/A video cards were introduced, competing manufacturers chose not to attempt to clone these incremental improvements on their VGA products. Instead, they began producing lower-cost adapters that offered even higher resolutions. These video cards fall into a category loosely known as Super VGA (SVGA).

SVGA provides capabilities that surpass those offered by the VGA adapter. Unlike the display adapters discussed so far, SVGA refers not to an adapter that meets a particular specification, but to a group of adapters that have different capabilities.

For example, one card might offer several resolutions (such as 800×600 and 1,024×768) that are greater than those achieved with a regular VGA, whereas another card might offer the same or even greater resolutions but also provide more color choices at each resolution. These cards have different capabilities; nonetheless, both are classified as SVGA.

The SVGA cards look much like their VGA counterparts. They have the same connectors, but because the technical specifications from different SVGA vendors vary tremendously, it is impossible to provide a definitive technical overview in this book. The connector is shown in Figure 15.8; the pinouts are shown in Table 15.4.

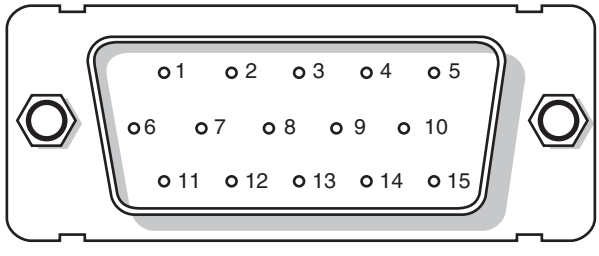

Figure 15.8 VGA connector used for SVGA and other VGA-based standards.

Table 15.4 Standard 15-pin VGA Connector Pinout

Pin #	Function	Direction	Pin #	Function	Direction
1	Red video	Out	9	Key (plugged hole)	
2	Green video	Out	10	Synch Ground	
3	Blue video	Out	11	Monitor ID 0	In
4	Monitor ID 2	In	12	Monitor ID 1	In
5	TTL Ground (monitor self-test)		13	Horizontal Synch	Out
6	Red analog ground		14	Vertical Synch	Out
7	Green analog ground		15	Monitor ID 3	In
8	Blue analog ground				

On the VGA cable connector that plugs into your video adapter, pin 9 is often pinless. Pin 5 is used only for testing purposes, and pin 15 is rarely used; these are often pinless as well. To identify the type of monitor connected to the system, some manufacturers use the presence or absence of the monitor ID pins in various combinations.

VESA SVGA Standards

The Video Electronics Standards Association includes members from various companies associated with PC and computer video products. In October 1989, VESA recognized that programming applications to support the many SVGA cards on the market was virtually impossible and proposed a standard for a uniform programmer's interface for SVGA cards; it is known as the VESA BIOS extension (VBE). VBE support might be provided through a memory-resident driver (used by older cards) or through additional code added to the VGA BIOS chip itself (the more common solution). The benefit of the VESA BIOS extension is that a programmer needs to worry about only one routine or driver to support SVGA. Various cards from various manufacturers are accessible through the common VESA interface. Today, VBE support is a concern primarily for real-mode DOS applications, usually older games, and for non-Microsoft operating systems that need to access higher resolutions and color depths. VBE supports resolutions up to 1,280×1,024 and color depths up to 24-bit (16.8 million colors), depending on the mode selected and the memory on the video card. VESA compliance is of virtually no consequence to Windows versions 95 and up. These operating systems use custom video drivers for their graphics cards.

Note

For a listing of VESA BIOS modes by resolution, color depth, and scan frequency, see "VESA SVGA Standards" in the Technical Reference portion of the DVD accompanying this book.

Integrated Video/Motherboard Chipsets

Although built-in video has been a staple of low-cost computing for a number of years, until the late 1990s most motherboard-based video simply moved the standard video components discussed earlier in this chapter to the motherboard. Many low-cost systems—especially those using the semiproprietary LPX motherboard form factor—have incorporated standard VGA-type video circuits on the motherboard. The performance and features of the built-in video differed only slightly from add-on cards using the same or similar chipsets, and in most cases the built-in video could be replaced by adding a video card. Some motherboard-based video also had provisions for memory upgrades.

◀◀ See "LPX," p. 208.

However, in recent years the move toward increasing integration on the motherboard has led to the development of chipsets that include 3D accelerated video and audio support as part of the chipset design. In effect, the motherboard chipset takes the place of most of the video card components listed earlier and uses a portion of main system memory as video memory. The use of main system memory for video memory is often referred to as *unified memory architecture (UMA)*, and although this memory-sharing method was also used by some built-in video that used its own chipset, it has become much more common with the rise of integrated motherboard chipsets.

The pioneer of integrated chipsets containing video (and audio) features was Cyrix. While Cyrix was owned by National Semiconductor, it developed a two-chip product called MediaGX. MediaGX incorporated the functions of a CPU, memory controller, sound, and video and made very low-cost computers possible (although with performance significantly slower than that of Pentium-class systems with similar clock speeds). National Semiconductor retained the MediaGX after it sold Cyrix to VIA Technologies. National Semiconductor went on to develop improved versions of the MediaGX, called the Geode GX1 and Geode GX2, for use in thin clients (a terminal that runs Windows and has a high-res display), interactive set-top boxes, and other embedded devices.

Intel became the next major player to develop integrated chipsets, with its 810 chipset for the Pentium III and Celeron processors. The 810 (codenamed Whitney before its official release) heralded the beginning of widespread industry support for this design. Intel later followed the release of the 810 series (810 and 810E) with the 815 series, most of which also feature integrated video.

The 810 chipset family supports relatively low-performance (PCI-equivalent) integrated graphics, whereas the 815 series chipsets with integrated video (815, 815E, 815EG, and 815G) support AGP-equivalent integrated 3D graphics with i740-class performance. Motherboards with the 815 or 815E chipset can also be equipped with an optional AGP slot for video card upgrades, whereas the 815P and 815EP chipsets lack integrated video and are used with separate AGP cards. Both the 810 and 815 series chipsets are designed to support recent and current Intel processors, such as the Pentium III and Celeron in their Socket 370 form factors. Both the 810 family and 815 family chipsets are two-piece sets: One chip contains the Graphics Memory Controller Hub, which replaces the traditional North Bridge chip and adds integrated video, and the other chip contains the I/O Controller Hub, which replaces the traditional South Bridge.

◀◀ See "Intel 810, 810E, and 810E2," p. 263, and "Intel 815, 815E, and 815EP," p. 266.

Intel is far from alone in its support for integrated chipsets; most other major chipset vendors also have developed similar integrated chipsets for use in low-cost computers and motherboards using both Intel and AMD CPUs, as shown in Table 15.5.

Table 15.5 Major Non-Intel Integrated Chipsets

Vendor	Chipset	Processors Supported	Number of Chips in Chipset	Notes
VIA Technologies	VIA Apollo PLE133	Pentium III/ Celeron/VIA C3 (Socket 370)	2	Incorporates Trident Blade3D graphics
VIA Technologies	VIA Apollo PLE133T	Pentium III/ Tualatin/ Celeron/ VIA C3 (Socket 370)	2	Incorporates Trident Blade3D graphics

Table 15.5 Continued

Vendor	Chipset	Processors Supported	Number of Chips in Chipset	Notes
VIA Technologies	VIA Apollo MVP4	Super Socket 7 (AMD K6 family, VIA Cyrix MII, Intel Pentium MMX)	2	Incorporates Trident Blade3D graphics
VIA Technologies	ProSavage PL133	Pentium III, Celeron, VIA C3	2	Incorporates S3 Savage 4 3D graphics; PC133 SDRAM
VIA Technologies	ProSavage PL133T	Pentium III/ Tualatin, Celeron, VIA C3	2	Incorporates S3 Savage 4 3D graphics with optional LCD, TV out; PC133 SDRAM
VIA Technologies	ProSavage PM133	Pentium III, Celeron, VIA C3	2	Incorporates S3 Savage 4 3D graphics with optional external AGP 4x; PC133 SDRAM
VIA Technologies	ProSavage KM133	AMD Athlon, Duron (Socket A)	2	Incorporates S3 Savage 4 3D graphics, with optional LCD and external AGP 4x; PC133 SDRAM
VIA Technologies	ProSavage P4M266	Pentium 4	2	Incorporates S3 Savage 8 3D graphics with optional external AGP 4x; DDR SDRAM
Silicon Integrated Systems (SiS)	SiS 530/ 5595	Super Socket 7 (AMD K6 family, Cyrix MII, Intel Pentium MMX)	2	Incorporates SiS6320 3D graphics
Silicon Integrated Systems (SiS)	SiS 620/ 5595	Pentium II/ III/Celeron (Slot 1 or Socket 370)	2	Incorporates SiS6320 3D graphics
Silicon Integrated Systems (SiS)	SiS 630	Pentium III/Celeron (Socket 370)	1	Incorporates SiS300 3D graphics; compatible with SiS Video Bridge
Silicon Integrated Systems (SiS)	SiS 630E	Pentium III/ Celeron (Socket 370)	1	Incorporates SiS300 3D graphics

Table 15.5 Continued

Vendor	Chipset	Processors Supported	Number of Chips in Chipset	Notes
Silicon Integrated Systems (SiS)	SiS 630S	Pentium III/ Celeron (Socket 370)	1	Incorporates SiS300 3D graphics; also supports external AGP 4X
Silicon Integrated Systems (SiS)	SiS 730S	AMD Athlon/ Duron (Socket A)	1	Incorporates 3D graphics; also supports external AGP 4X
Silicon Integrated Systems (SiS)	SiS 740	AMD Athlon/ Duron (Socket A)	2	Multiple monitor and TV-out; PC133 SDRAM or DDR SDRAM
Silicon Integrated Systems (SiS)	SiS 650	Pentium 4	2	Supports external AGP 4x; multiple monitor and TV-out
Acer Labs	Aladdin TNT2	Pentium II/III/Celeron (Slot A and Socket A)	2	Based on NVIDIA's RIVA TNT2 3D video chipset
NVIDIA	nForce	AMD Athlon/Duron (Socket A)	2	Based on GeForce 2 GPU; supports DVI and TV-out and external AGP 4x
ATI	RADEON IGP 330/340	Pentium 4	2	Based on RADEON VE; 340 also supports TV-out and FSB up to 533MHz; supports ATI's IXP 200/250 (USB 2.0, 10/100 Ethernet, ATA 100; IXP 250 adds manage-ability features) South Bridge or third-party South Bridge
ATI	RADEON IGP 320	AMD Athlon/ Duron (Socket A)	2	Based on RADEON VE supports ATI's IXP 200/250 (USB 2.0, 10/100 Ethernet, ATA 100; IXP 25 adds manageability features) South Bridge or third-party South Bridge

Although a serious 3D gamer will not be satisfied with the performance of most integrated chipsets (NVIDIA's nForce and ATI's RADEON IGPs being notable exceptions), business, home/office, and casual gamers will find that integrated chipset-based video—particularly those that support advanced AGP 2x and faster 3D functions—are satisfactory in performance and provide cost savings compared with separate video cards. If you decide to buy a motherboard with an integrated chipset, I recommend that you select one that also supports external AGP 4x video. This enables you to add a faster video card in the future if you decide you need it.

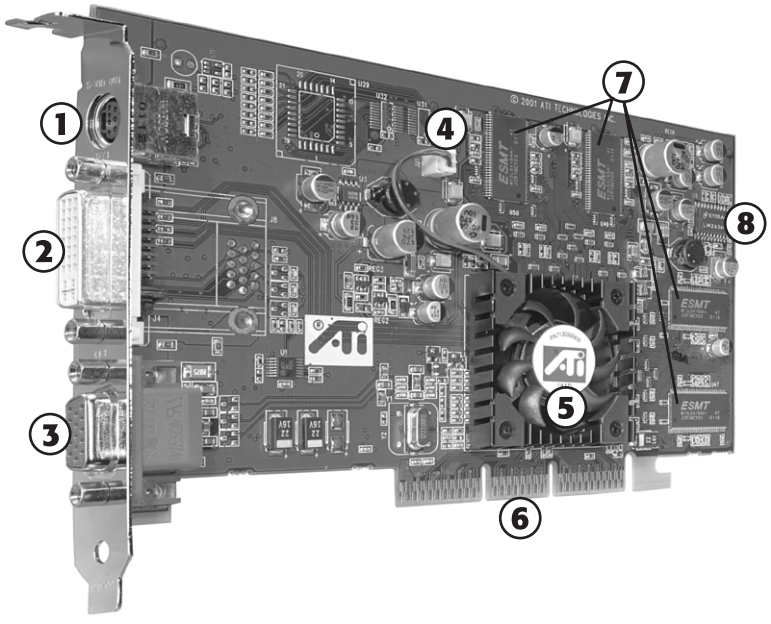
Video Adapter Components

All video display adapters contain certain basic components, such as the following:

- Video BIOS.
- Video processor/video accelerator.
- Video memory.
- Digital-to-analog converter (DAC). Formerly a separate chip, the DAC is often incorporated into the video processor/accelerator chip on recent chipsets. The DAC is not necessary on a purely digital subsystem (digital video card and display), but because most display subsystems have an analog VGA video card, an analog display, or both, video cards will continue to have DAC features for some time to come.
- Bus connector.
- Video driver.

Figure 15.9 indicates the locations of many of these components on a typical video card.

Virtually all video adapters on the market today use chipsets that include 3D acceleration features. The following sections examine these components and features in greater detail.



The Video BIOS

Video adapters include a BIOS that is similar in construction but completely separate from the main system BIOS. (Other devices in your system, such as SCSI adapters, might also include their own BIOS.) If you turn on your monitor first and look quickly, you might see an identification banner for your adapter's video BIOS at the very beginning of the system startup process.

Similar to the system BIOS, the video adapter's BIOS takes the form of a ROM (read-only memory) chip containing basic instructions that provide an interface between the video adapter hardware and the software running on your system. The software that makes calls to the video BIOS can be a standalone application, an operating system, or the main system BIOS. The programming in the BIOS chip enables your system to display information on the monitor during the system POST and boot sequences, before any other software drivers have been loaded from disk.

◀◀ See "BIOS Basics," p. 356.

The video BIOS also can be upgraded, just like a system BIOS, in one of two ways. The BIOS uses a rewritable chip called an EEPROM (electrically erasable programmable read-only memory) that you can upgrade with a utility the adapter manufacturer provides. Alternatively, you might be able to completely replace the chip with a new one—again, if supplied by the manufacturer and if the manufacturer did not hard solder the BIOS to the printed circuit board. Most recent video cards use a surface-mounted BIOS chip rather than a socketed chip. A BIOS you can upgrade using software is referred to as a *flash* BIOS, and most current-model video cards that offer BIOS upgrades use this method.

1. TV out
2. DVI out (can be converted to VGA out)
3. VGA out
4. Power connector for fan
5. Fan/heatsink over RADEON 7500 GPU with intergrated DAC
6. AGP 4x slot connector
7. 64MB DDR memory
8. Voltage regulator chip

Figure 15.9 The ATI RADEON 7500 is a typical example of a mid-range video card optimized for gaming and dual-display support. Like most recent graphics cards, it uses a nonremovable flash BIOS (not visible in this photo). *Photo courtesy of ATI Technologies, Inc.*

Video BIOS upgrades are sometimes necessary in order to use an existing adapter with a new operating system, or when the manufacturer encounters a significant bug in the original programming. Occasionally, a BIOS upgrade is necessary because of a major revision to the video card chipset's video drivers. As a general rule, the video BIOS is a component that falls into the "if it ain't broke, don't fix it" category. Try not to let yourself be tempted to upgrade just because you've discovered that a new BIOS revision is available. Check the documentation for the upgrade, and unless you are experiencing a problem the upgrade addresses, leave it alone.

◀◀ See "Video Adapter BIOS," p. 481.

The Video Processor

The video processor, or chipset, is the heart of any video adapter and essentially defines the card's functions and performance levels. Two video adapters built using the same chipset often have many of the same capabilities and deliver comparable performance. Also, the software drivers that operating systems and applications use to address the video adapter hardware are written primarily with the

chipset in mind. You often can use a driver intended for an adapter with a particular chipset on any other adapter using the same chipset. Of course, cards built using the same chipset can differ in the amount and type of memory installed, so performance can vary.

Several main types of processors are used in video adapters; these technologies are compared in Table 15.6.

Table 15.6 Video Processor Technologies

Processor Type	Where Video Processing Takes Place	Relative Speed	Relative Cost	How Used Today
Frame-buffer	Computer's CPU.	Very slow	Very low	Obsolete; mostly ISA video cards
Graphics coprocessor	Video card's own processor.	Very fast	Very high	CAD and engineering workstations
Graphics accelerator	Video chip draws lines, circles, shapes; CPU sends commands to draw them.	Fast	Low to moderate	All mainstream video cards; is combined with 3D graphics processor on current cards
3D graphics processor	Video cards 3D graphics processing units (in accelerator chipset) render polygons and add lighting and shading effects as needed.	Fast 2D and 3D display	Most price ranges depending on chipset, memory, and RAMDAC speed	All gaming optimized video cards and almost all mainstream video cards

Identifying the Video and System Chipsets

Before you purchase a system or a video card, you should find out which chipset the video card or video circuit uses or, for systems with integrated chipset video, which integrated chipset the system uses. This allows you to have

- Better comparisons of card or system to others
- Access to technical specifications
- Access to reviews and opinions
- Better buying decisions
- Choice of card manufacturer or chipset manufacturer support and drivers

Because video card performance and features are critical to enjoyment and productivity, find out as much as you can before you buy the system or video card by using the chipset or video card manufacturer's Web site and third-party reviews.

The Vendor List on the DVD has information on most of the popular video chipset manufacturers, including how to contact them. You should note that NVIDIA (the leading video chipset vendor) makes only chipsets, whereas ATI (the #2 video vendor) makes branded video cards and supplies chipsets to vendors. This means a wide variety of video cards use the same chipset.

Video RAM

Most video adapters rely on their own onboard memory that they use to store video images while processing them; although some AGP video cards can use system memory for 3D textures, this feature is not universally supported. Many low-cost systems with onboard video use the UMA feature to share the main system memory. In any case, the memory on the video card or borrowed from the system performs the same tasks.

The amount of memory on the adapter or used by integrated video determines the maximum screen resolution and color depth the device can support. You often can select how much memory you want on a particular video adapter; for example, 16MB, 32MB, and 64MB are common choices today. Although adding more memory is not guaranteed to speed up your video adapter, it can increase the speed if it enables a wider bus (from 64 bits wide to 128 bits wide) or provides nondisplay memory as a cache for commonly displayed objects. It also enables the card to generate more colors and higher resolutions and, for AGP cards (see the following), allows 3D textures to be stored and processed on the card, rather than in slower main memory.

Many types of memory have been used with video adapters. These memory types are summarized in Table 15.7.

Table 15.7 Memory Types Used in Video Display Adapters

Memory Type	Definition	Relative Speed	Usage
FPM DRAM	Fast Page-Mode RAM	Slow	Low-end ISA cards; obsolete
VRAM[1]	Video RAM	Fast	Expensive; obsolete
WRAM[1]	Window RAM	Fast	Expensive; obsolete
EDO DRAM	Extended Data Out DRAM	Moderate	Low-end PCI-bus
SDRAM	Synchronous DRAM	Fast	Low-end PCI/AGP
MDRAM	Multibank DRAM	Fast	Little used; obsolete
SGRAM	Synchronous Graphics DRAM	Very fast	High-end PCI/AGP; replaced by DDR SDRAM
DDR SDRAM	Double-Data Rate SDRAM	Very fast	High-end AGP

1. VRAM and WRAM are dual-ported memory types that can read from one port and write data through the other port. This improves performance by reducing wait times for accessing the video RAM compared to FPM DRAM and EDO DRAM.

To learn more about memory types used on older video cards (FPD DRAM, VRAM, WRAM, EDO DRAM, and MDRAM), see Chapter 15 of *Upgrading and Repairing PCs, 12th Edition*, available in electronic form on the DVD packaged with this book.

SGRAM, SDRAM, and DDR SDRAM have replaced VRAM, WRAM, and MDRAM as high-speed video RAM solutions. SGRAM, SDRAM, and DDR SDRAM are derived from popular motherboard memory technologies. Their high speeds and low production costs have enabled even inexpensive video cards to have 16MB or more of high-speed RAM onboard.

SDRAM

Synchronous DRAM (SDRAM) is the same type of RAM used on many current systems based on processors such as the Pentium III, Pentium 4, Athlon, and Duron. The SDRAMs found on video cards are usually surface-mounted individual chips; on a few early models, a small module containing SDRAMs might be plugged into a proprietary connector. This memory is designed to work with bus speeds up to 200MHz and provides performance just slightly slower than SGRAM. SDRAM is used primarily in current low-end video cards and chipsets such as NVIDIA's GeForce2 MX and ATI's RADEON VE.

SGRAM

Synchronous Graphics RAM (SGRAM) was designed to be a high-end solution for very fast video adapter designs. SGRAM is similar to SDRAM in its capability to be synchronized to high-speed buses up to 200MHz, but it differs from SDRAM by including circuitry to perform block writes to increase the speed of graphics fill or 3D Z-buffer operations. Although SGRAM is faster than SDRAM, most video card makers have dropped SGRAM in favor of even faster DDR SDRAM in their newest products.

DDR SDRAM

Double Data Rate SDRAM (also called DDR SDRAM) is the most recent video RAM technology. It is designed to transfer data at speeds twice that of conventional SDRAM by transferring data on both the rising and falling parts of the processing clock cycle. Today's top-of-the-line and mid-range video cards based on chipsets such as NVIDIA's GeForce 4 and GeForce 3 Ti and ATI's RADEON 8000 and 7000 series use DDR SDRAM for video memory.

Video RAM Speed

Video cards with the same type of 3D graphics processor chip (GPU) onboard might use different speeds of memory. For example, the Gainward MX400 Golden Sample card (based on the GeForce2 MX400) uses 3.5ns memory, whereas the Hercules 3D Prophet II MX400, based on the same GeForce2 MX400 GPU, uses 5.5ns memory. Both video cards run at the same standard speeds, but the Gainward card can be overclocked to a much higher speed because its memory is faster. Video card makers also match different memory speeds with different versions of the same basic GPU.

Unless you dig deeply into the technical details of a particular 3D graphics card, determining whether a particular card uses SDRAM, DDR SDRAM, or SGRAM can be difficult. Because none of today's 3D accelerators feature upgradeable memory, I recommend that you look at the performance of a given card and choose the card with the performance, features, and price that's right for you.

RAM Calculations

The amount of memory a video adapter needs to display a particular resolution and color depth is based on a mathematical equation. A location must be present in the adapter's memory array to display every pixel on the screen, and the resolution determines the number of total pixels. For example, a screen resolution of 1,024×768 requires a total of 786,432 pixels.

If you were to display that resolution with only two colors, you would need only 1 bit of memory space to represent each pixel. If the bit has a value of 0, the dot is black, and if its value is 1, the dot is white. If you use 24 bits of memory space to control each pixel, you can display more than 16.7 million colors because 16,777,216 combinations are possible with a 4-digit binary number (2^{24}=16,777,216). If you multiply the number of pixels necessary for the screen resolution by the number of bits required to represent each pixel, you have the amount of memory the adapter needs to display that resolution. Here is how the calculation works:

1,024×768 = 786,432 pixels×24 bits per pixel
= 18,874,368 bits
= 2,359,296 bytes
= 2.25MB

As you can see, displaying 24-bit color (16,777,216 colors) at 1,024×768 resolution requires exactly 2.25MB of RAM on the video adapter. Because most adapters support memory amounts of only 256KB, 512KB, 1MB, 2MB, or 4MB, you would need to use a video adapter with at least 4MB of RAM onboard to run your system using that resolution and color depth.

To use the higher-resolution modes and greater numbers of colors common today, you would need much more memory on your video adapter than the 256KB found on the original IBM VGA. Table 15.8 shows the memory requirements for some of the most common screen resolutions and color depths used for 2D graphics operations, such as photo editing, presentation graphics, desktop publishing, and Web page design.

Table 15.8 Video Display Adapter Minimum Memory Requirements for 2D Operations

Resolution	Color Depth	No. Colors	Onboard Video RAM	Actual Memory Required
640×480	8-bit	256	512KB	307,200 bytes
640×480	16-bit	65,536	1MB	614,400 bytes
640×480	24-bit	16,777,216	1MB	921,600 bytes
800×600	8-bit	256	512KB	480,000 bytes
800×600	16-bit	65,536	1MB	960,000 bytes
800×600	24-bit	16,777,216	2MB	1,440,000 bytes
1,024×768	16-bit	65,536	2MB	1,572,864 bytes
1,024×768	24-bit	16,777,216	4MB	2,359,296 bytes
1,280×1,024	16-bit	65,536	4MB	2,621,440 bytes
1,280×1,024	24-bit	16,777,216	4MB	3,932,160 bytes

From this table, you can see that a video adapter with 2MB can display 65,536 colors in 1,024×768 resolution mode, but for a true color (16.8 million colors) display, you would need to upgrade to 4MB.

3D video cards require more memory for a given resolution and color depth because the video memory must be used for three buffers: the front buffer, back buffer, and Z-buffer. The amount of video memory required for a particular operation varies according to the settings used for the color depth and Z-buffer. Triple buffering allocates more memory for 3D textures than double-buffering but can slow down performance of some games. The buffering mode used by a given 3D video card usually can be adjusted through its properties sheet.

Table 15.9 lists the memory requirements for 3D cards in selected modes. For memory sizes used by other combinations of color depth and Z-buffer depth, see the eTesting Labs' Memory Requirements for 3D Applications Web site at the following address:

`www.etestinglabs.com/benchmarks/3dwinbench/d5memfor3d.asp`

Table 15.9 Video Display Adapter Memory Requirements for 3D Operations

Resolution	Color Depth	Z-Buffer Depth	Buffer Mode	Actual Memory Used	Onboard Video Memory Size Required
640×480	16-bit	16-bit	Double	1.76MB	2MB
			Triple	2.34MB	4MB
	24-bit	24-bit	Double	2.64MB	4MB
			Triple	3.52MB	4MB
	32-bit	32-bit	Double	3.52MB	4MB
			Triple	4.69MB	8MB
800×600	16-bit	16-bit	Double	2.75MB	4MB
			Triple	3.66MB	4MB
	24-bit	24-bit	Double	4.12MB	8MB
			Triple	5.49MB	8MB
	32-bit	32-bit	Double	5.49MB	8MB
			Triple	7.32MB	8MB
1,024×768	16-bit	16-bit	Double	4.12MB	8MB
			Triple	5.49MB	8MB
	24-bit	24-bit	Double	6.75MB	8MB
			Triple	9.00MB	16MB
	32-bit[1]	32-bit	Double	9.00MB	16MB
			Triple	12.00MB	16MB
1,280×1,024	16-bit	16-bit	Double	7.50MB	8MB
			Triple	10.00MB	16MB
	24-bit	24-bit	Double	11.25MB	16MB
			Triple	15.00MB	16MB
	32-bit	32-bit	Double	15.00MB	16MB
			Triple	20.00MB	32MB
1,600×1,280	16-bit	16-bit	Double	10.99MB	16MB
			Triple	14.65MB	16MB
	24-bit	24-bit	Double	16.48MB	32MB
			Triple	21.97MB	32MB
	32-bit	32-bit	Double	21.97MB	32MB
			Triple	29.30MB	32MB

Note

Although 3D adapters typically operate in a 32-bit mode (refer to Table 15.9), this does not necessarily mean they can produce more than the 16,277,216 colors of a 24-bit true-color display. Many video processors and video memory buses are optimized to move data in 32-bit words, and they actually display 24-bit color while operating in a 32-bit mode, instead of the 4,294,967,296 colors you would expect from a true 32-bit color depth.

If you spend a lot of time working with graphics and want to enjoy 3D games, you might want to invest in a 24-bit (2D) or 32-bit (3D) video card with at least 32MB or more of RAM. Although 2D operations can be performed with as little as 4MB of RAM, 32-bit color depths for realistic 3D operation with large Z-buffers use most of the RAM available on a 16MB card at 1,024×768 resolution; higher resolutions use more than 16MB of RAM at higher color depths. Today's video cards provide more RAM and more 2D/3D performance for less money than ever before. Note that recent and

current-model video cards don't use socketed memory anymore, so you must be sure to buy a video card with all the memory you might need now and in the future. Otherwise, you must replace a card with inadequate memory.

Windows Can't Display More Than 256 Colors

If you have a video card with 1MB or more of video memory, but the Windows Display Settings properties sheet won't allow you to select a color depth greater than 256 colors, Windows might have misidentified the video card during installation or the video driver installation might be corrupted.To see which video card Windows recognizes, click the Advanced Properties button, and then click the Adapter tab if necessary. Your adapter type might be listed either by the video card's brand name and model or by the video card's chipset maker and chipset model.

If the card model or chipset appears to be incorrect or not specific enough, click Change and see what other drivers your system lists that appear to be compatible, or use a utility program provided by your video card/chipset maker to identify your card and memory size. Then, manually select the correct driver if necessary. If the video card model or chipset appears to be correct, open the System properties sheet, locate the Device Manager, and remove the display adapter listing. Restart the computer and Windows will redetect the video card/chipset and install the correct driver.

Video Bus Width

Another issue with respect to the memory on the video adapter is the width of the bus connecting the graphics chipset and memory on the adapter. The chipset is usually a single large chip on the card that contains virtually all the adapter's functions. It is wired directly to the memory on the adapter through a local bus on the card. Most of the high-end adapters use an internal memory bus that is 64 bits or even 128 bits wide. This jargon can be confusing because video adapters that take the form of separate expansion cards also plug into the main system bus, which has its own speed rating. When you read about a 64-bit or 128-bit video adapter, you must understand that this refers to the local video bus and that the bus connecting the adapter to the system is actually the 32- or 64-bit PCI or AGP bus on the system's motherboard.

◀◀ See "System Bus Types, Functions, and Features," p. 295.

The Digital-to-Analog Converter

The digital-to-analog converter on a video adapter (commonly called a RAMDAC) does exactly what its name describes. The RAMDAC is responsible for converting the digital images your computer generates into analog signals the monitor can display. The speed of the RAMDAC is measured in MHz; the faster the conversion process, the higher the adapter's vertical refresh rate. The speeds of the RAMDACs used in today's high-performance video adapters range from 300MHz to 350MHz. Most of today's video card chipsets include the RAMDAC function inside the 3D accelerator chip, but some dual-display-capable video cards use a separate RAMDAC chip to allow the second display to work at different refresh rates than the primary display.

The benefits of increasing the RAMDAC speed include higher vertical refresh rates, which allows higher resolutions with flicker-free refresh rates (72Hz–85Hz or above). Typically, cards with RAMDAC speeds of 300MHz or above display flicker-free (75Hz or above) at all resolutions up to 1,920×1,200. Of course, as discussed earlier in this chapter, you must ensure that any resolution you want to use is supported by both your monitor and video card.

The Bus

You've learned in this chapter that certain video adapters were designed for use with certain system buses. Earlier bus standards, such as the IBM MCA, ISA, EISA, and VL-Bus, have all been used for VGA and other video standards. Because of their slow performances, all are now obsolete; current video

cards are made exclusively for either the PCI or AGP bus standard. In July 1992, Intel Corporation introduced Peripheral Component Interconnect (PCI) as a blueprint for directly connecting microprocessors and support circuitry. It then extended the design to a full expansion bus with Release 2 in 1993; the current standard is Release 2.1. Popularly termed a mezzanine bus, PCI combines the speed of a local bus with microprocessor independence. PCI video adapters, similar to VL-Bus adapters, can dramatically increase video performance when compared with ISA adapters. PCI video adapters, by their design, are meant to be Plug and Play (PnP), which means they require little configuration. The PCI standard virtually replaced the older VL-Bus standard overnight and has dominated Pentium-class video until recently. Although the PCI bus remains the best general-purpose standard for expansion cards, the current king of high-speed video is AGP.

◀◀ See "Accelerated Graphics Port," p. 322.

◀◀ See "The PCI Bus," p. 316.

The most recent system bus innovation is the Accelerated Graphics Port (AGP), an Intel-designed dedicated video bus that delivers a maximum bandwidth up to 16 times larger than that of a comparable PCI bus. AGP is essentially an enhancement to the existing PCI bus; it's intended for use with only video adapters and provides them with high-speed access to the main system memory array. This enables the adapter to process certain 3D video elements, such as texture maps, directly from system memory rather than having to copy the data to the adapter memory before the processing can begin. This saves time and eliminates the need to upgrade the video adapter memory to better support 3D functions.

Note

Although the earliest AGP cards had relatively small amounts of onboard RAM, most recent and all current implementations of card-based AGP use large amounts of on-card memory and use a memory aperture (a dedicated memory address space above the area used for physical memory) to transfer data more quickly to and from the video card's own memory. Integrated chipsets featuring built-in AGP do use system memory for all operations, including texture maps.

Ironically, the memory aperture used by AGP cards can actually cause out-of-memory errors with Windows 9x and Windows Me on systems with more than 512MB of RAM. See Microsoft Knowledge Base document #Q253912 for details.

Although it was designed with the Pentium II in mind, AGP is not processor dependent. However, it does require support from the motherboard chipset, and AGP cards require a special expansion slot, which means you can't upgrade an existing non-AGP system to use AGP without replacing the motherboard.

All recent nonintegrated motherboard chipsets from major vendors (Intel, Acer Labs, VIA Technologies, and SiS) for Pentium II and newer Intel processors and AMD Athlon and Duron processors support some level of AGP. However, some of the integrated chipsets don't support an AGP slot.

◀◀ See "Socket 7 (and Super7)," p. 96.

Even with the proper chipset, however, you can't take full advantage of AGP's capabilities without the proper operating system support. AGP's Direct Memory Execute (DIME) feature uses main memory instead of the video adapter's memory for certain tasks to lessen the traffic to and from the adapter. Windows 98/Me and Windows 2000/XP support this feature, but Windows 95 and Windows NT 4 do not.

Four speeds of AGP are available: 1X, 2X, 4X, and 8X (AGP 3.0). AGP 1X and 2X are part of the original AGP Specification 1.0; AGP 4X is part of AGP Specification 2.0; and AGP 8X is part of AGP Specification 3.0. AGP 1X is the original version of AGP, running at 66MHz clock speed and a

maximum transfer rate of 266MB/second (twice the speed of 32-bit PCI video cards). AGP 1X is obsolete, having been replaced by AGP 2X, which runs at 133MHz and offers transfer rates up to 533MB/second. The most common version of AGP supports 4X mode, which offers maximum transfer rates in excess of 1GB/second; AGP 4x also can be used with AGP 2x-compatible motherboards (although its performance then is limited to 2X). Intel's AGP 8X mode, which provides transfer rates in excess of 2GB/second, is now known as AGP Specification 3.0; motherboards using AGP 3.0 can handle either AGP 3.0 or 1.5v AGP 2.0 video cards. Even though AGP 3.0 (AGP 8X) is the fastest version of AGP, if you plan to use an AGP video card with an older system first, you might want to specify a 1.5v AGP 4X video card instead. Such cards will work in both AGP 4X (AGP 2.0) and AGP 8X (AGP 3.0) systems. Because of the bandwidth required by AGP 3.0, systems featuring this version of AGP also support DDR333 memory, which is significantly faster than DDR266 (also known as PC2100 memory). AGP 3.0 was announced in 2000, but support for the standard requires the development of motherboard chipsets that were not introduced until mid-2002. By late 2002, AGP 3.0 video cards should be widely available.

Caution

Should you check motherboard-video card compatibility before you buy? Yes, because early AGP cards (especially those based on Intel's i740 chipset) were designed strictly for the original AGP Pentium II-based motherboards. Some AGP users have Super Socket 7 motherboards instead, and some early AGP cards don't work with these motherboards. Check with both the video card and motherboard vendors before you make your purchase.

Intel's 845 chipset for the Pentium 4 works with 1.5v AGP 4X video cards but not with AGP 2X/4X cards running at 3.3v.

◀◀ See "Socket 7 (and Super7)," p. 96.

The high and mid-range sectors of the video card market have shifted almost completely to AGP 4X; PCI video cards are being relegated to replacements for older systems. Ironically, because of the high popularity of AGP today, you might pay more for a slower PCI video card than for an AGP card with similar features.

Note

Many low-cost systems implement AGP video on the motherboard without providing an AGP expansion slot for future upgrades. This prevents you from changing to a faster or higher memory AGP video card in the future, although you might be able to use slower PCI video cards. For maximum flexibility, get your AGP video on a card.

VL-Bus, PCI, and AGP have some important differences, as Table 15.10 shows.

Table 15.10 Local Bus Specifications

Feature	VL-Bus	PCI	AGP
Theoretical maximum	132MB/sec	132MB/sec[1]	533MB/sec throughput (2X) 1.06GB/sec throughput (4X) 2.12GB/sec throughput (8X)
Slots[2]	3 (typical)	4/5 (typical)	1
Plug and Play support	No	Yes	Yes
Cost	Inexpensive	Slightly higher	Similar to PCI

Table 15.10 Continued

Feature	VL-Bus	PCI	AGP
Ideal use	Low-cost 486	High-end 486, Pentium, P6	Pentium II/III/Celeron/4, K6, Athlon, Duron
Status	Obsolete	Current	Current

1. At the 66MHz bus speed and 32 bits. Throughput is higher on the 100MHz system bus.

The Video Driver

The software driver is an essential, and often problematic, element of a video display subsystem. The driver enables your software to communicate with the video adapter. You can have a video adapter with the fastest processor and the most efficient memory on the market but still have poor video performance because of a badly written driver.

Video drivers generally are designed to support the processor on the video adapter. All video adapters come equipped with drivers the card manufacturer supplies, but often you can use a driver the chipset maker created as well. Sometimes you might find that one of the two provides better performance than the other or resolves a particular problem you are experiencing.

Most manufacturers of video adapters and chipsets maintain Web sites from which you can obtain the latest drivers; drivers for chipset-integrated video are supplied by the system board or system vendor. A driver from the chipset manufacturer can be a useful alternative, but you should always try the adapter manufacturer's driver first. Before purchasing a video adapter, you should check out the manufacturer's site and see whether you can determine how up-to-date the available drivers are. At one time, frequent driver revisions were thought to indicate problems with the hardware, but the greater complexity of today's systems means that driver revisions are a necessity. Even if you are installing a brand-new model of a video adapter, be sure to check for updated drivers on the manufacturer's Web site for best results.

The video driver also provides the interface you can use to configure the display your adapter produces. On a Windows 9x/Me/2000/XP system, the Display Control Panel identifies the monitor and video adapter installed on your system and enables you to select the color depth and screen resolution you prefer. The driver controls the options that are available for these settings, so you can't choose parameters the hardware doesn't support. For example, the controls would not allow you to select a 1,024×768 resolution with 24-bit color if the adapter had only 1MB of memory.

When you click the Advanced button on the Settings page, you see the Properties dialog box for your particular video display adapter. The contents of this dialog box can vary, depending on the driver and the capabilities of the hardware. Typically, on the General page of this dialog box, you can select the size of the fonts (large or small) to use with the resolution you've chosen. Windows 98/Me/2000 (but not Windows XP) also add a control to activate a convenient feature. The Show Settings Icon on Task Bar check box activates a tray icon that enables you to quickly and easily change resolutions and color depths without having to open the Control Panel. This feature is often called QuickRes. The Adapter page displays detailed information about your adapter and the drivers installed on the system, and it enables you to set the Refresh Rate for your display; with Windows XP, you can use the List All Modes button to view and choose the resolution, color depth, and refresh rate with a single click. The Monitor page lets you display and change the monitor's properties and switch monitor drivers if necessary. In Windows XP, you can also select the refresh rate on this screen.

If your adapter includes a graphics accelerator, the Performance page contains a Hardware Acceleration slider you can use to control the degree of graphic display assistance provided by your adapter hardware. In Windows XP, the Performance page is referred to as the Troubleshoot page.

Setting the Hardware Acceleration slider to the Full position activates all the adapter's hardware acceleration features.

Moving the slider one notch to the left addresses mouse display problems by disabling the hardware's cursor support in the display driver. This is the equivalent of adding the `SWCursor=1` directive to the `[Display]` section of the `System.ini` file.

Moving the slider another notch (to the second notch from the right) prevents the adapter from performing certain bit-block transfers. With some drivers, this setting also disables memory-mapped I/O. This is the equivalent of adding the `Mmio=0` directive to the `[Display]` section of `System.ini` and the `SafeMode=1` directive to the `[Windows]` section of `Win.ini` (and the `SWCursor` directive mentioned previously).

Moving the slider to the None setting (the far left) adds the `SafeMode=2` directive to the `[Windows]` section of the `Win.ini` file. This disables all hardware acceleration support and forces the operating system to use only the device-independent bitmap (DIB) engine to display images, rather than bit-block transfers. Use this setting when you experience frequent screen lockups or receive invalid page fault error messages.

Note

If you need to disable any of the video hardware features listed earlier, this often indicates a buggy video or mouse driver. If you download and install updated video and mouse drivers, you should be able to revert to full acceleration.

In most cases, another tab called Color Management is also available. You can select a color profile for your monitor to enable more accurate color matching for use with graphics programs and printers.

Video cards with advanced 3D acceleration features often have additional properties; these are discussed later in this chapter.

Multiple Monitors

Windows 98/Me and Windows 2000/XP include a video display feature that Macintosh systems have had for years: the capability to use multiple monitors on one system. Windows 98/Me support up to nine monitors (and video adapters), each of which can provide a different view of the desktop. Windows 2000 and Windows XP support up to ten monitors and video adapters. When you configure a Windows 98/Me or Windows 2000/XP system to use multiple monitors, the operating system creates a virtual desktop—that is, a display that exists in video memory that can be larger than the image actually displayed on a single monitor. You use the multiple monitors to display various portions of the virtual desktop, enabling you to place the windows for different applications on separate monitors and move them around at will.

Unless you use multiple-head video cards, each monitor you connect to the system requires its own video adapter. So, unless you have nine bus slots free, the prospects of seeing a nine-screen Windows display are slim, for now. However, even two monitors can be a boon to computing productivity.

On a multimonitor Windows 98/Me system, one display is always considered to be the primary display. The primary display can use any PCI or AGP VGA video adapter that uses a Windows 98/Me minidriver with a linear frame buffer and a packed (nonplanar) format, meaning that most of the brand-name adapters sold today are eligible. Additional monitors are called secondaries and are much more limited in their hardware support. To install support for multiple monitors, be sure you have only one adapter installed first; then reboot the system, and install each additional adapter one at a time. For more information about multiple-monitor support for Windows 98/Me, including a list of supported adapters, see the Microsoft Knowledge Base article #Q182708.

It's important that the computer correctly identifies which one of the video adapters is the primary one. This is a function of the system BIOS, and if the BIOS on your computer does not let you select which device should be the primary VGA display, it decides based on the order of the PCI slots in the machine. You should, therefore, install the primary adapter in the highest-priority PCI slot. In some cases, an AGP adapter might be considered secondary to a PCI adapter. Depending on the BIOS used by your system, you might need to check in various places for the option to select the primary VGA display. For example, the Award BIOS used by the ASUS A7V133 motherboard for Socket A processors lists this option, which it calls Primary VGA BIOS, in the Boot menu. In contrast, the Phoenix BIOS used by the Intel DB815-EEA motherboard lists this option, which it calls Default Primary Video Adapter, in the Video Configuration menu.

◀◀ See "The PCI Bus," p. 316.

After the hardware is in place, you can configure the display for each monitor from the Display control panel's Settings page. The primary display is always fixed in the upper-left corner of the virtual desktop, but you can move the secondary displays to view any area of the desktop you like. You can also set the screen resolution and color depth for each display individually. For more information about configuring multiple-monitor support in Windows 98/Me, see Microsoft Knowledge Base article #Q179602. The multiple-monitor support included with Windows 2000 and Windows XP is somewhat different from that of Windows 98/Me. These versions of Windows support ten monitors, rather than nine as with Windows 98/Me. In addition, because Windows 2000 and XP use different display drivers than Windows 98/Me, some configurations that work with 98/Me might not work with Windows 2000/XP. For more information about configuring multiple-monitor support in Windows 2000, see Microsoft Knowledge Base article #Q238886. For details of the display cards compatible with Windows XP in multiple-display modes, see Microsoft Knowledge Base article #Q307397.

Windows XP also supports DualView, an enhancement to Windows 2000's multiple-monitor support. DualView supports the increasing number of dual-head video cards as well as notebook computers connected to external displays. With systems supporting DualView, the first video port is automatically assigned to the primary monitor. On a notebook computer, the primary display is the built-in LCD display.

Even if your BIOS enables you to specify the primary video card and you use video cards that are listed as compatible, determining exactly which display cards will work successfully in a multimonitor configuration can be difficult. Microsoft provides a list of compatible display cards in the `Hcl.txt` file located on the Windows 2000 CD-ROM, but this list does not contain the latest video cards and chipsets from NVIDIA, ATI, or other companies, nor does it take into account changes in supported chipsets caused by improved drivers. Unfortunately, the online version of the Microsoft Windows Hardware Quality Labs Hardware Compatibility List (`www.Microsoft.com/hcl`) doesn't list information about multiple-monitor support for any version of Windows.

Consequently, you should check with your video card or chipset maker for the latest information on Windows 2000 or Windows XP and multiple-monitor support issues.

Because new chipsets, updated drivers, and combinations of display adapters are a continuous issue for multiple-monitor support, I recommend the following online resources:

- `http://www.realtimesoft.com/ultramon`. Home of the UltraMon multiple-monitor support enhancement program ($24.95) and an extensive database of user-supplied multiple-monitor configurations for Windows 98/Me, Windows 2000/XP, and Linux

- `http://www.digitalroom.net` (click Tech Articles and then Multiple Monitor Guide). Excellent tips on multiple-monitor setups and links to other resources

Multiple-monitor support can be enabled through either of the following:

- Installation of a separate AGP or PCI graphics card for each monitor you want to use
- Installation of a single AGP or PCI graphics card that can support two or more monitors

A card that supports multiple monitors (also called a multiple-head or dual-head card) saves slots inside your system.

Depending on the card in question, you can use the multiple-monitor feature in a variety of ways. For example, the ATI RADEON VE, RADEON 7500, and RADEON 8500 all feature a 15-pin analog VGA connector for CRTs, a DVI-I digital/analog connector for digital LCD panels, and a TV-out connector for S-video or composite output to TVs and VCRs. Thus, you can connect any of the following to these cards:

- One analog LCD or CRT display **and** one digital LCD display
- Two analog LCD or CRT displays (when the DVI-I–to–VGA adapter is used)
- One analog LCD or CRT display **and** one TV
- One digital LCD display **and** one TV

Some of the major multiple-head cards on the market are listed in Table 15.11.

Table 15.11 Major Multiple-Head Video Cards

Brand	Model	Type(s)	Number of Monitors Supported	Accelerator Chip(s)	Notes
Appian Graphics	Jeronimo Pro	PCI	2 or 4	3D Labs Permedia 2 3D (2 or 4)	Supports analog CRTs and LCD displays
Appian Graphics	Jeronimo 2000	AGP, PCI	2	3D Labs Permedia 3 (2)	Supports analog CRTs and LCD displays
Appian Graphics	Hurricane	AGP, PCI	2	ATI RADEON VE 3D (1)	Supports analog CRTs and LCD displays
ATI	RADEON VE	AGP	2	ATI RADEON VE 3D (1)	Supports analog CRTs and LCD displays; supports digital flat panel (DVI) and TV-out

Table 15.11 Continued

Brand	Model	Type(s)	Number of Monitors Supported	Accelerator Chip(s)	Notes
ATI	RADEON 7500[1]	AGP	2	ATI RADEON 7500 3D (1)	Supports analog CRTs and LCD displays; supports digital flat panel (DVI) and TV-out
ATI	RADEON 8500[1]	AGP	2	ATI RADEON 8500 3D (1)	Supports analog CRTs and LCD displays; supports digital flat panel (DVI) and TV-out
Gainward	CARDEXpert GeForce2 MX Twin View	AGP	2	NVIDIA GeForce2 (1) MX TwinView	Supports analog CRTs and LCD displays; supports TV out option
Hercules	Hercules 3D Prophet II MX Dual-Display	AGP	2	NVIDIA GeForce2 (1) MX TwinView	Supports analog CRTs and LCD displays; supports TV-out option
LeadTek	WinFast GeForce2 MX DH Pro	AGP	2	NVIDIA GeForce2 (1) MX TwinView	Supports analog CRTs and LCD displays; supports TV-out option
Matrox	Millennium G200 MMS	PCI	2 or 4	MGA-G200 3D (2 or 4)	Supports analog CRT and digital flat panel (DVI PanelLink); supports TV-out
Matrox	Millennium G450	AGP, PCI	2	Matrox G450 3D (1)	Supports analog CRT and LCD displays; supports TV-out; supports digital flat panel (DVI)[2]
Matrox	Millennium G550	AGP, PCI	2	Matrox G550 3D (1)	Supports analog CRT and LCD displays; supports TV-out; supports digital flat panel (DVI)

1. The RADEON 8500LE (slower version of the RADEON 8500) and RADEON 7500 GPU chips are also used by various third-party suppliers to produce video cards with multiple-display support.

2. Optional adapter required.

3D Graphics Accelerators

Since the late 1990s, 3D acceleration—once limited to exotic add-on cards designed for hardcore gameplayers—has become commonplace in the PC world. Although business software has yet to

embrace 3D imaging, full-motion graphics are used in sports, first-person shooters, team combat, driving, and many other types of PC gaming. Because even low-cost integrated chipsets offer some 3D support and 3D video cards are now in their fifth generation of development, virtually any user of a recent-model computer has the ability to enjoy 3D lighting, perspective, texture, and shading effects in their favorite games. The latest 3D sports games provide lighting and camera angles so realistic that a casual observer could almost mistake the computer-generated game for an actual broadcast, and the latest 3D accelerator chips enable fast PCs to compete with high-performance dedicated game machines, such as Sony's PlayStation 2 and Nintendo's GameCube (as well as the PC-based Microsoft Xbox) for the mind and wallet of the hard-core gameplayer.

How 3D Accelerators Work

To construct an animated 3D sequence, a computer can mathematically animate the sequences between keyframes. A keyframe identifies specific points. A bouncing ball, for example, can have three keyframes: up, down, and up. Using these frames as a reference point, the computer can create all the interim images between the top and bottom. This creates the effect of a smoothly bouncing ball.

After it has created the basic sequence, the system can then refine the appearance of the images by filling them in with color. The most primitive and least effective fill method is called *flat shading*, in which a shape is simply filled with a solid color. *Gouraud shading*, a slightly more effective technique, involves the assignment of colors to specific points on a shape. The points are then joined using a smooth gradient between the colors.

A more processor-intensive, and much more effective, type of fill is called *texture mapping*. The 3D application includes patterns—or textures—in the form of small bitmaps that it tiles onto the shapes in the image, just as you can tile a small bitmap to form the wallpaper for your Windows desktop. The primary difference is that the 3D application can modify the appearance of each tile by applying perspective and shading to achieve 3D effects. When lighting effects that simulate fog, glare, directional shadows, and others are added, the 3D animation comes very close indeed to matching reality.

Until the late 1990s, 3D applications had to rely on support from software routines to convert these abstractions into live images. This placed a heavy burden on the system processor in the PC, which has a significant impact on the performance not only of the visual display, but also of any other applications the computer might be running. Starting in the period from 1996 to 1997, chipsets on most video adapters began to take on many of the tasks involved in rendering 3D images, greatly lessening the load on the system processor and boosting overall system performance.

Because there have now been five generations of 3D accelerators (depending on what you count as a "generation"), and more and more memory is standard to enable high-resolution 3D animations, most high-quality 3D accelerator cards cost at least $200, and some models packed with 64MB of DDR SDRAM and the latest accelerator technology can sell for as much as $350–$400. Both video games and 3D animation programs are taking advantage of their capability to render smooth, photo-realistic images at high speeds and in real time.

Fortunately, users with less-demanding 3D performance requirements often can purchase low-end products based on the previous generation of 3D accelerator chips for about $100. These cards typically provide more-than-adequate performance for 2D business applications. Some mid-range and high-end 3D accelerators also support dual-display and TV-out capabilities, enabling you to work and play at the same time.

3D technology has added an entirely new vocabulary to the world of video display adapters. Before purchasing a 3D accelerator adapter, you should familiarize yourself with some of the terms and concepts involved in the 3D image generation process.

The basic function of 3D software is to convert image abstractions into the fully realized images that are then displayed on the monitor. The image abstractions typically consist of the following elements:

- *Vertices*. Locations of objects in three-dimensional space, described in terms of their x, y, and z coordinates on three axes representing height, width, and depth.
- *Primitives*. The simple geometric objects the application uses to create more complex constructions, described in terms of the relative locations of their vertices. This serves not only to specify the location of the object in the 2D image, but also to provide perspective because the three axes can define any location in three-dimensional space.
- *Textures*. Two-dimensional bitmap images or surfaces designed to be mapped onto primitives. The software enhances the 3D effect by modifying the appearance of the textures, depending on the location and attitude of the primitive. This process is called *perspective correction*. Some applications use another process, called *MIP mapping*, which uses different versions of the same texture that contain varying amounts of detail, depending on how close the object is to the viewer in the three-dimensional space. Another technique, called *depth cueing*, reduces the color and intensity of an object's fill as the object moves farther away from the viewer.

Using these elements, the abstract image descriptions must then be rendered, meaning they are converted to visible form. Rendering depends on two standardized functions that convert the abstractions into the completed image that is displayed onscreen. The standard functions performed in rendering are

- *Geometry*. The sizing, orienting, and moving of primitives in space and the calculation of the effects produced by the virtual light sources that illuminate the image
- *Rasterization*. The converting of primitives into pixels on the video display by filling the shapes with properly illuminated shading, textures, or a combination of the two

A modern video adapter that includes a chipset capable of 3D video acceleration has special built-in hardware that can perform the rasterization process much more quickly than if it were done by software (using the system processor) alone. Most chipsets with 3D acceleration perform the following rasterization functions right on the adapter:

- *Scan conversion*. The determination of which onscreen pixels fall into the space delineated by each primitive
- *Shading*. The process of filling pixels with smoothly flowing color using the flat or Gouraud shading technique
- *Texture mapping*. The process of filling pixels with images derived from a 2D sample picture or surface image
- *Visible surface determination*. The identification of which pixels in a scene are obscured by other objects closer to the viewer in three-dimensional space
- *Animation*. The process of switching rapidly and cleanly to successive frames of motion sequences
- *Antialiasing*. The process of adjusting color boundaries to smooth edges on rendered objects

Common 3D Techniques

Virtually all 3D cards use the following techniques:

- *Fogging*. Fogging simulates haze or fog in the background of a game screen and helps conceal the sudden appearance of newly rendered objects (buildings, enemies, and so on).

- *Gouraud shading*. Interpolates colors to make circles and spheres look more rounded and smooth.
- *Alpha blending*. One of the first 3D techniques, alpha blending creates translucent objects onscreen, making it a perfect choice for rendering explosions, smoke, water, and glass. Alpha blending also can be used to simulate textures, but it is less realistic than environment-based bump mapping (see the section "Environment-Based Bump Mapping," later in this chapter).

Because they are so common, data sheets for advanced cards frequently don't mention them, although these features are present.

Advanced 3D Techniques

The following are some of the latest techniques that leading 3D accelerator cards use. Not every card uses every technique.

Stencil Buffering

Stencil buffering is a technique useful for games such as flight simulators, in which a static graphic element—such as a cockpit windshield frame, which is known as a HUD (heads up display) and used by real-life fighter pilots—is placed in front of dynamically changing graphics (such as scenery, other aircraft, sky detail, and so on). In this example, the area of the screen occupied by the cockpit windshield frame is not re-rendered. Only the area seen through the "glass" is re-rendered, saving time and improving frame rates for animation.

Z-Buffering

A closely related technique is *Z-buffering*, which originally was devised for computer-aided drafting (CAD) applications. The Z-buffer portion of video memory holds depth information about the pixels in a scene. As the scene is rendered, the Z-values (depth information) for new pixels are compared to the values stored in the Z-buffer to determine which pixels are in "front" of others and should be rendered. Pixels that are "behind" other pixels are not rendered. This method increases speed and can be used along with stencil buffering to create volumetric shadows and other complex 3D objects.

Environment-Based Bump Mapping

This technique introduces special lighting and texturing effects to simulate the rough texture of rippling water, bricks, and other complex surfaces. It combines three separate texture maps (for colors, for height and depth, and for environment—including lighting, fog, and cloud effects). This creates enhanced realism for scenery in games and could also be used to enhance terrain and planetary mapping, architecture, and landscape-design applications. This represents a significant step beyond alpha blending.

Texture Mapping Filtering Enhancements

To improve the quality of texture maps, several filtering techniques have been developed, including MIP mapping, bilinear filtering, trilinear filtering, and anisotropic filtering. These techniques and several others are explained here:

- *Bilinear filtering*. Improves the image quality of small textures placed on large polygons. The stretching of the texture that takes place can create blockiness, but bilinear filtering applies a blur to conceal this visual defect.
- *MIP mapping*. Improves the image quality of polygons that appear to recede into the distance by mixing low-res and high-res versions of the same texture; a form of antialiasing.

- *Trilinear filtering*. Combines bilinear filtering and MIP mapping, calculating the most realistic colors necessary for the pixels in each polygon by comparing the values in two MIP maps. This method is superior to either MIP mapping or bilinear filtering alone.

Note

Bilinear and trilinear filtering work well for surfaces viewed straight-on but might not work so well for oblique angles (such as a wall receding into the distance).

- *Anisotropic filtering*. Some video card makers use another method, called anisotropic filtering, for more realistically rendering oblique-angle surfaces containing text. This technique is used when a texture is mapped to a surface that changes in two of three spatial domains, such as text found on a wall down a roadway (for example, advertising banners at a raceway). The extra calculations used take time, and for that reason, it can be disabled.
- *T-buffer*. This technology eliminates aliasing (errors in onscreen images due to an undersampled original) in computer graphics, such as the "jaggies" seen in onscreen diagonal lines; motion stuttering; and inaccurate rendition of shadows, reflections, and object blur. The T-buffer replaces the normal frame buffer with a buffer that accumulates multiple renderings before displaying the image. Unlike some other 3D techniques, T-buffer technology doesn't require rewriting or optimization of 3D software to use this enhancement. The goal of T-buffer technology is to provide a movie-like realism to 3D rendered animations. The downside of enabling antialiasing using a card with T-buffer support is that it can dramatically impact the performance of an application. This technique originally was developed by now-defunct 3dfx. However, this technology is incorporated into Microsoft DirectX 8.0 and above, enabling other brands of video cards to use it.
- *Integrated transform and lighting*. The 3D display process includes transforming an object from one frame to the next and handling the lighting changes that result from those transformations. Many 3D cards put the CPU in charge of these functions, but some graphics accelerators—such as NVIDIA's GeForce2, GeForce3, and GeForce4 series and ATI's RADEON 8500, RADEON 7500, and original RADEON—integrate separate transform and lighting engines into the accelerator chip for faster 3D rendering, regardless of CPU speed. For more information, see the NVIDIA and ATI Web sites.
- *Full-Screen antialiasing*. This technology reduces the jaggies visible at any resolution by adjusting color boundaries to provide gradual, rather than abrupt, color changes. Whereas early 3D products used antialiasing for certain objects only, the latest accelerators from NVIDIA and ATI use this technology for the entire display. ATI's SMOOTHVISION supports up to 10 antialiasing settings, enabling the user to select the best mix of performance and visual quality. NVIDIA's GeForce4 Ti series uses an improved version of the GeForce3's multisampling method, known in the GeForce4 Ti as Accuview AA. Accuview AA combines anisotropic filtering with edge antialiasing to provide both high-quality and high-performance antialiasing.
- *Virtual texture*. This technology uses a logical address space for texture memory that is mapped to physical memory addresses on the graphics accelerator chip, on the graphics card, and in main system memory. The small 4KB logical pages allows texture data used with recent 3D games to be fetched on an as-needed basis and rendered immediately as soon as a small amount of texture data is retrieved, preventing slow-downs in graphics rendering caused by the normal practice of retrieving the entire texture before rendering begins. For more information, see the 3Dlabs Web site.
- *Vertex skinning*. Also referred to as vertex blending, this technique blends the connection between two angles, such as the joints in an animated character's arms or legs. NVIDIA's

GeForce2, 3, and 4 series cards use a software technique to perform blending at two matrices, whereas the ATI RADEON series chips use a more realistic hardware-based technique called 4-matrix skinning.

- *Keyframe interpolation*. Also referred to as vertex morphing, this technique animates the transitions between two facial expressions, allowing realistic expressions when skeletal animation can't be used or isn't practical. See the ATI Web site for details.
- *Programmable vertex and pixel shading*. The NVIDIA GeForce3's nfiniteFX technology enables software developers to customize effects such as vertex morphing and pixel shading (an enhanced form of bump mapping for irregular surfaces that enables per-pixel lighting effects), rather than applying a narrow range of predefined effects. The NVIDIA GeForce4 Ti's nfiniteFXII pixel shader supports up to four textures, whereas its dual vertex shaders provide high-speed rendering up to 50% faster than the GeForce3. The ATI RADEON 8500's version is called SmartShader, supports more complex programs than nfiniteFX, and provides comparable quality to nfiniteFXII. SmartShader is also supported by DirectX 8.1.

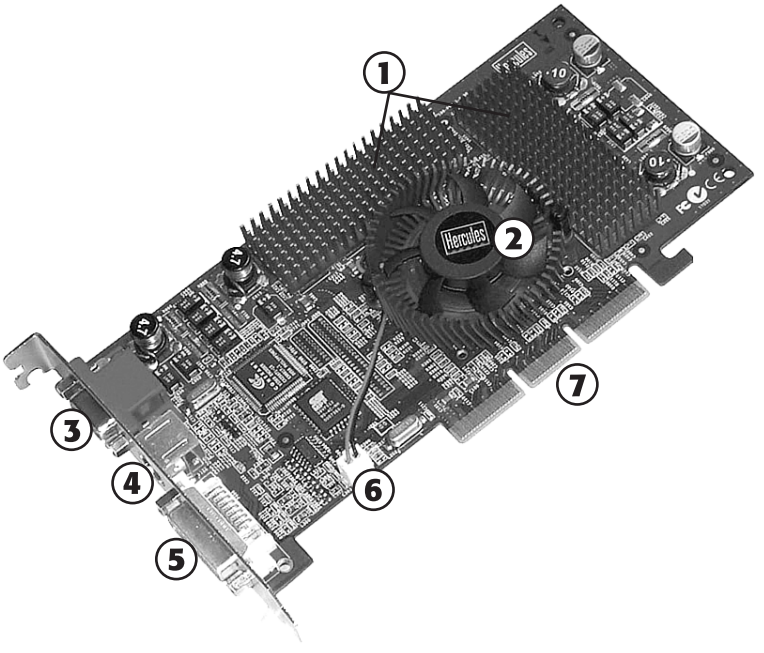
Single- Versus Multiple-Pass Rendering

Various video card makers handle application of these advanced rendering techniques differently. The current trend is toward applying the filters and basic rendering in a single pass rather than multiple passes. Video cards with single-pass rendering and filtering typically provide higher frame-rate performance in 3D-animated applications and avoid the problems of visible artifacts caused by errors in multiple floating-point calculations during the rendering process.

Hardware Acceleration Versus Software Acceleration

Compared to software-only rendering, hardware-accelerated rendering provides faster animation. Although most software rendering would create more accurate and better-looking images, software rendering is too slow. Using special drivers, these 3D adapters can take over the intensive calculations needed to render a 3D image that software running on the system processor formerly performed. This is particularly useful if you are creating your own 3D images and animation, but it is also a great enhancement to the many modern games that rely extensively on 3D effects. Note that motherboard-integrated video solutions, such as Intel's 810 and 815 series, typically have significantly lower 3D performance because they use the CPU for more of the 3D rendering than 3D video adapter chipsets do.

To achieve greater performance, many of the latest 3D accelerators run their accelerator chips at very high speeds, and some even allow overclocking of the default RAMDAC frequencies. Just as CPUs at high speeds produce a lot of heat, so do high-speed video accelerators. Both the chipset and the memory are heat sources, so most mid-range and high-end 3D accelerator cards feature a fan to cool the chipset. Also, some high-end 3D accelerators such as the Hercules 3D Prophet III (based on the NVIDIA GeForce3 chipset) use finned passive heatsinks to cool the memory chips, as shown in Figure 15.10.



Software Optimization

It's important to realize that the presence of an advanced 3D-rendering feature on any given video card is meaningless unless game and application software designers optimize their software to take advantage of the feature. Although various 3D standards exist (OpenGL, Glide, and Direct 3D), video card makers provide drivers that make their games play with the leading standards. Because some cards do play better with certain games, you should read the reviews in publications such as *Maximum PC* to see how your favorite graphics card performs with them.

Some video cards allow you to perform additional optimization by adjusting settings for OpenGL, Direct 3D, RAMDAC, and bus clock speeds, as well as other options.

Note

If you want to enjoy the features of your newest 3D card immediately, be sure to purchase the individual retail-packaged version of the card from a hardware vendor. These packages typically come with a sampling of games (full and demo versions) designed or compiled to take advantage of the card with which they're sold. The lower-cost OEM or "white box" versions of video cards are sold without bundled software, come only with driver software, and might differ in other ways from the retail advertised product. Some even use modified drivers, use slower memory or RAMDAC components, or lack special TV-out or other features. Some 3D card makers use different names for their OEM versions to minimize confusion, but others don't. Also, some card makers sell their cards in bulk packs, which are intended for upgrading a large organization with its own support staff. These cards might lack individual documentation or driver CDs and also might lack some of the advanced hardware features found on individual retail-pack video cards.

1. 64MB DDR SDRAM with passive heatsinks
2. Cooling fan over NVIDIA GeForce3 graphics processor
3. 15-pin analog VGA out connector
4. TV/video out connector
5. DVI connector for digital LCD panel
6. Power connector for cooling fan
7. 4x AGP slot connector

Application Programming Interfaces

Application programming interfaces (APIs) provide hardware and software vendors a means to create drivers and programs that can work quickly and reliably across a wide variety of platforms. When APIs exist, drivers can be written to interface with the API rather than directly with the operating system and its underlying hardware.

Currently, the leading game APIs include SGI's OpenGL and Microsoft's Direct 3D. OpenGL and Direct 3D (part of DirectX) are available for virtually all leading graphics cards. A third popular game API is Glide, an enhanced version of OpenGL that is restricted to graphics cards that use 3Dfx chipsets, which are no longer on the market.

Although the video card maker must provide OpenGL support, Microsoft provides support for Direct3D as part of a much larger API called DirectX.

The latest version of DirectX is DirectX 8.1, which enhances 3D video support and provides other advanced gaming features. For more information about DirectX or to download the latest version, see Microsoft's DirectX Web site at `www.microsoft.com/directx`.

3D Chipsets

Virtually every mainstream video adapter in current production features a 3D acceleration-compatible chipset. With several generations of 3D adapters on the market from the major vendors, keeping track of the latest products can be difficult. Table 15.12 lists the major 3D chipset manufacturers, the various chipsets they make, and the video adapters that use them.

The following manufacturers' products are not included in Table 15.12 for the reasons listed:

- *3Dfx Interactive*. Out of business; obtain last-available official and third-party drivers from `www.voodoofiles.com`.
- *3Dlabs*. Now manufacturers Open GL-compatible workstation cards only.
- *Intel*. No longer manufactures graphics boards.
- *Micron*. No longer manufactures chipsets.
- *S3*. Desktop graphics assets transferred to joint venture called S3 Graphics, which primarily makes integrated chipsets. S3 has changed its name to SonicBLUE and specializes in digital music and Internet products. S3 sold its Diamond Fire GL workstation graphics product line to ATI (which continues to develop and sell it), but it continues to support its Diamond-branded desktop and workstation cards at `www.sonicblue.com`.
- *VideoLogic*. No longer manufactures graphics boards.

See Chapter 15 in both *Upgrading and Repairing PCs, 12th Edition* and *13th Edition* on this book's DVD for more information about these companies' products and other older chipsets.

Note

In each manufacturer's section, the following symbols are used to provide a ranking within that manufacturer's chipsets only: NEW—RECENT—OLD. Generally, NEW chipsets provide the fastest 3D performance and advanced 3D rendering features. RECENT chipsets, although lacking some of the speed or features of NEW chipsets, are also worthwhile, especially for those on a budget. OLD chipsets are generally superseded by RECENT and NEW chipsets and therefore are not recommended. OLD chipsets are listed by chipset only, whereas NEW and RECENT chipsets list selected video cards using those chipsets. Be sure to use this information in conjunction with application-specific and game-specific tests to help you choose the best card/chipset solution for your needs. Only products believed to be currently available are listed; consult the chipset vendors' Web sites for the latest information about third-party video card sources using a specific chipset.

Upgrading or Replacing Your Video Card

With current developments in rock-bottom video card pricing, improvements in 3D display technology, and massive amounts of high-speed memory available on new video cards (up to 64MB!), it

makes little sense today to add most upgrades to an existing video card. The component-level upgrades that can be added generally include

- TV tuners, permitting you to watch cable or broadcast TV on your monitor
- Video capture devices, allowing you to capture still or moving video to a file

If you need better 3D performance, more memory, or support for DVI digital displays, you need to replace your video card.

TV Tuner and Video Capture Upgrades

Most video cards don't have TV tuner and video capture upgrade features built in. New cards with these features tend to be either in the middle to high range of their manufacturers' price structures or less expensive but of poor quality.

These features are exciting if you are already into video editing, want to add video to your Web site, or are trying to create CD-R/CD-RW archives of your home video. If you have an up-to-date video card with acceptable 2D and 3D performance and at least 16MB of video RAM, compare the price of the add-ons to the price of a new card with these features. You'll probably find the add-ons to be less expensive. If your card has 8MB of video RAM or less, I'd recommend replacing it with a new card with these features. Look at sample video captures before making your decision because all video capture solutions require image compression with at least some loss of quality. If you have a digital camcorder with IEEE-1394 (also called FireWire or i.Link) ports, you should purchase an IEEE-1394 interface board instead to use high-quality pure digital video that needs no conversion. Note that ATI's All-in-Wonder RADEON 8500 DV includes an IEEE-1394 port as well as TV-in capability, allowing you to use a single card for high-performance business and gaming graphics as well as digital and analog video capture.

The USB port found on recent systems can be used to connect TV tuner and video-capture options compatible with any manufacturer's video card, such as the ATI TV-Wonder USB Edition or Hauppauge's WinTV-USB. Because the wide variety of TV and computer hardware on the market can cause compatibility problems with USB TV/capture devices, be sure to check review sites such as `http://computers.cnet.com` or `http://www.epinions.com`.

Note

If you're planning to upgrade to a new video card in the next year or two, find out whether the TV or video add-on you want to buy for your present video card will work with the new model. If it's a TV tuner, you might need to consider other cards from the same vendor your current video card came from. If you're unsure of future compatibility, hold off on your purchase or consider buying a card with the desired features included.

Warranty and Support

Because a video card can go through several driver changes during its effective lifetime (about three years or two operating-system revisions), buying a video card from a major manufacturer usually assures you of better support during the card's lifetime. If you buy a card that uses widely available chipsets (such as NVIDIA's), you might be able to try a different vendor's version of drivers or use the chipset vendor's "generic" drivers if you don't get satisfactory support from your card vendor.

Keep in mind that using generic drivers (chipset level) or a different brand of drivers can cause problems if your original card's design was tweaked from the chipset maker's reference design. Look at the vendor's technical support forums or third-party discussions on newsgroups, computer information Web sites such as ZDNet, or magazine Web sites to get a feel for the stability, reliability, and usefulness

of a vendor's support and driver services. These sources generally also provide alternatives in case of difficulties with a specific brand or chipset. If you use Windows Me, Windows 2000, or Windows XP, make sure you use WHQL-certified drivers for best results. These drivers have been passed by Microsoft's Windows Hardware Quality Labs and might be available through Windows Update or from the vendor's own Web site.

Comparing Video Cards with the Same Chipset

Many manufacturers create a line of video cards with the same chipset to sell at different pricing points. Why not save some dollars and get the cheapest model? Why not say "price is no object" and get the most expensive one? When you're faced with various cards in the "chipsetX" family, look for differences such as those shown in Table 15.13.

Table 15.13 Comparing Video Cards with the Same Features

Feature	Effect on You
RAMDAC speed	Most current 3D accelerator cards use a 300MHz or faster RAMDAC, which provides flicker-free resolutions beyond 1,024×768. However, less-expensive cards in older designs often used a slower RAMDAC, which reduces maximum and flicker-free resolutions. If you use a 17" or larger monitor, this could be an eye-straining problem.
Amount of RAM	Although AGP video cards can use AGP memory (a section of main memory borrowed for texturing), performing as much work as possible on the card's own memory is still faster. PCI cards must perform all functions within their own memory. Less expensive cards in a chipset family often have lower amounts of memory onboard, and most curent-model cards aren't expandable. Buy a card with enough memory for your games or applications—today and tomorrow; at least 16MB or more for business and 32MB or more for gaming, 3D graphics, and video-related work.
Memory type	Virtually all video cards on the market today use SDRAM or its faster variants (SGRAM or DDR SDRAM). Any of these provides you with high performance in business applications, although DDR SDRAM is preferable when running high-resolution, high-quality 3D games faster.
Core clock speed	Many suppliers adjust the recommended speed of graphics controllers in an effort to provide users with maximum performance. Sometimes the supplier can choose to exceed the rated specification of the graphics chip. Be cautious: Current controller chips are large and can overheat. An overclocked device in an open system with great airflow might work, or it might fail in a period of months from overstress of the circuitry. If you have questions about the rated speed of a controller, check the chip supplier's Web site. Many reputable companies do use overclocked parts, but the best vendors supply large heatsinks or powered fans to avoid overheating. Some vendors even provide on-card temperature monitoring.
RAM Speed (ns rating)	Just as faster system RAM improves overall computer performance, faster video card RAM improves video card performance. Some high-performance 3D video cards now use DDR SDRAM memory chips with a 4ns or faster access time.
TV-out	Once a rare feature, many mid-range and most high-end video cards now feature TV out, enabling you to display DVD movies or video games on a big-screen TV. Some of the latest models have hardware-based MPEG-2 compression for higher video quality in less disk space.

Video Cards for Multimedia

Multimedia—including live full-motion video feeds, videoconferencing, and animations—has become an important element of the personal computing industry and is helping to blur the once-solid lines between computer and broadcast media. As the demand for multimedia content increases, so do the capabilities of the hardware and software used to produce the content. Video is just one, albeit important, element of the multimedia experience, and the graphics adapters on the market today reflect the demand for these increased capabilities. Producing state-of-the-art multimedia content today often requires that the PC be capable of interfacing with other devices, such as cameras, VCRs, and television sets, and many video adapters are now equipped with these capabilities.

Other multimedia technologies, such as 3D animation, place an enormous burden on a system's processing and data-handling capabilities, and many manufacturers of video adapters are redesigning their products to shoulder this burden more efficiently.

The following sections examine some of the video adapter components that make these technologies possible and practical, including VFC, VAFC, VMC, and VESA VIP.

Because none of these specifications for internal video feature connectors has become a true industry standard, some manufacturers of auxiliary video products—such as dedicated 3D accelerator boards and MPEG decoders—have taken an alternative route through the standard VGA connector.

Video Feature Connectors

To extend the capabilities of the VGA standard beyond direct connections to a monitor, several auxiliary connector standards have been devised, first by individual card makers and later by VESA.

Three early attempts to create a common connector were the Video Feature Connector (VFC) that IBM devised in 1987, the VESA Advanced Feature Connector (VAFC), and the VESA Media Channel (VMC). These connector designs were not widely used, though.

Note

If you are interested in reading more about VFC, VAFC, and VMC, see "Video Feature Connectors," in the technical reference section of the DVD with this book.

VESA Video Interface Port

The most recent attempt at a standard interface between video cards and other video devices is the VESA Video Interface Port (VESA VIP), originally introduced in 1997. Version 2, the latest version of this standard, was introduced in October 1998.

The VESA VIP provides a dedicated connection designed to allow video cards to connect with one or more third-party hardware devices, such as MPEG-2 or HDTV decoders, video digitizers, video encoders, and so on. A dedicated connection prevents competition with other data movement on the PCI bus.

VIP is more widely supported than previous standards, but it exists in two versions (1.1 and 2.0) and is implemented in various ways by card vendors. For example, some versions of certain ATI video cards—such as the Xpert 99, Xpert 128, and Rage Magnum—use a 40-pin proprietary connector called the AMC connector, which also works as a 26-pin VIP connector. To avoid VESA VIP-compatibility problems, check the compatibility list for both the video card and the device you want to connect. You might need to purchase an adapter cable to connect the device to your card. ATI stopped adding the AMC connector to its products in 1999, and most other video card makers have also discontinued support for the VESA VIP port due to lack of demand.

Replacements for the VESA VIP and Other Video Connectors

Currently, most systems interface with video devices through their USB or IEEE-1394 ports. Add-on TV tuner cards and USB such as the ATI TV Wonder VE can be used with most DirectX-compatible video chipsets from ATI and NVIDIA for video capture. The ATI All-in-Wonder series provides TV-in, TV-out, and full-power graphics support in a single slot. The latest version, the ATI All-in-Wonder RADEON 8500 DV, also has IEEE-1394 ports for use with DV camcorders as well as S-video and composite input and output ports.

Video Output Devices

When video technology first was introduced, it was based on television. However, a difference exists between the signals used by a television and those used by a computer. In the United States, the National Television System Committee (NTSC) established color TV standards in 1953. Some other countries, such as Japan, followed this standard. Many countries in Europe, though, developed more sophisticated standards, including Phase Alternate Line (PAL) and Sequential Couleur Avec Mémoire (SECAM). Table 15.14 shows the differences among these standards.

Table 15.14 Television Versus Computer Monitors

Standard	Year Est.	Country	Lines	Rate
			Television	
NTSC	1953 (color) 1941 (b&w)	U.S., Japan	525	60 fields/sec
PAL	1941	Europe[1]	625	50 fields/sec
SECAM	1962	France	625	25 fields/sec
			Computer	
VGA	1987	U.S.	640×480[2]	72Hz

Field = 1/2 (.5 frame)

1. England, Holland, and West Germany.

2. VGA is based on more lines and uses pixels (480) versus lines; genlocking is used to lock pixels into lines and synchronize computers with TV standards.

A video-output (or VGA-to-NTSC) adapter enables you to display computer screens on a TV set or record them onto videotape for easy distribution. These products fall into two categories: those with genlocking (which enables the board to synchronize signals from multiple video sources or video with PC graphics) and those without. Genlocking provides the signal stability necessary to obtain adequate results when recording to tape, but it isn't necessary for using a television as a video display.

VGA-to-NTSC converters are available as internal expansion boards, external boxes that are portable enough to use with a laptop for presentations on the road, and TV-out ports on the rear of many mid-range and high-end video cards using chipsets from NVIDIA, ATI, and others. Indeed, many laptop and notebook systems these days come equipped with a built-in VGA-to-NTSC converter.

The converter does not replace your existing video adapter but instead connects to the adapter using an external cable. In addition to VGA input and output ports, a video output board has a video output interface for S-video and composite video.

Most VGA-to-TV converters support the standard NTSC television format and might also support the European PAL format. The resolution these devices display on a TV set or record on videotape often is

limited to straight VGA at 640×480 pixels, although some TV-out ports on recent video cards can also display 800×600 resolution. The converter also might contain an antiflicker circuit to help stabilize the picture because VGA-to-TV products, as well as TV-to-VGA solutions, often suffer from a case of the jitters.

Video Capture Devices

You can capture individual screen images or full-motion video for reuse in several ways, including

- 3D accelerator cards with TV-in ports
- TV tuner cards
- USB or parallel port-based devices such as TV tuner/capture devices discussed earlier or a dedicated device such as the SnapMAGIC (available from `www.snapnsend.com`)
- Webcams with video input ports

These units capture still or moving images from NTSC video sources, such as camcorders and VCRs. Although image quality is limited by the input signal, the results are still good enough for presentations and desktop publishing applications. These devices work with 8-, 16-, and 24-bit VGA cards and usually accept video input from VHS, Super VHS, and Hi-8 devices. As you might expect, however, Super VHS and Hi-8 video sources give better results, as do configurations using more than 256 colors. For the best results, use DV camcorders equipped with IEEE-1394 (i.Link/FireWire) connectors; these can output high-quality digital video direct to your computer without the need to perform an analog-to-digital conversion. Although a few computers feature built-in IEEE-1394 ports, you must install an IEEE-1394 add-in card into most computers if you want to capture output from a DV camcorder.

Desktop Video Boards

You can also capture NTSC (television) signals to your computer system for display or editing. In other words, you can literally watch TV in a window on your computer. When capturing video, you should think in terms of digital versus analog. The biggest convenience of an analog TV signal is efficiency; it is a compact way to transmit video information through a low bandwidth pipeline. The disadvantage is that although you can control how the video is displayed, you can't edit it.

Actually capturing and recording video from external sources and saving the files onto your PC requires special technology. To do this, you need a device called a *video capture board* (also called a TV tuner, video digitizer, or video grabber).

Note

In this context, the technical nomenclature again becomes confusing because the term *video* here has its usual connotation; that is, it refers to the display of full-motion photography on the PC monitor. When evaluating video hardware, be sure to distinguish between devices that capture still images from a video source and those that capture full-motion video streams.

Today, video sources come in two forms:

- Analog
- Digital

Analog video can be captured from traditional sources such as broadcast or cable TV, VCRs, and camcorders using VHS or similar tape standards. This process is much more demanding of storage space and system performance than still images are. Here's why.

The typical computer screen was designed to display mainly static images. The storing and retrieving of these images requires managing huge files. Consider this: A single, full-screen color image in an uncompressed format can require as much as 2MB of disk space; a 1-second video would therefore require 45MB. Likewise, any video transmission you want to capture for use on your PC must be converted from an analog NTSC signal to a digital signal your computer can use. On top of that, the video signal must be moved inside your computer at 10 times the speed of the conventional ISA bus structure. You need not only a superior video card and monitor, but also an excellent expansion bus, such as PCI or AGP.

Considering that full-motion video can consume massive quantities of disk space, it becomes apparent that data compression is all but essential. Compression and decompression apply to both video and audio. Not only does a compressed file take up less space, it also performs better simply because less data must be processed. When you are ready to replay the video/audio, the application decompresses the file during playback. In any case, if you are going to work with video, be sure that your hard drive is large enough and fast enough to handle the huge files that can result.

Compression/decompression programs and devices are called *codecs*. Two types of codecs exist: hardware-dependent codecs and software (or hardware-independent) codecs. Hardware codecs typically perform better; however, they require additional hardware—either an add-on card or a high-end video card with hardware codecs built in. Software codes do not require hardware for compression or playback, but they typically do not deliver the same quality or compression ratio. Two of the major codec algorithms are

- *JPEG (Joint Photographic Experts Group).* Originally developed for still images, JPEG can compress and decompress at rates acceptable for nearly full-motion video (30fps). JPEG still uses a series of still images, which makes editing easier. JPEG is typically lossy (meaning that a small amount of the data is lost during the compression process, slightly diminishing the quality of the image), but it can also be lossless. JPEG compression functions by eliminating redundant data for each individual image (intraframe). Compression efficiency is approximately 30:1 (20:1–40:1).
- *MPEG (Motion Picture Experts Group).* MPEG by itself compresses video at approximately a 30:1 ratio, but with precompression through oversampling, the ratio can climb to 100:1 and higher, while retaining high quality. Thus, MPEG compression results in better, faster videos that require less storage space. MPEG is an interframe compressor. Because MPEG stores only incremental changes, it is not used during editing phases.

If you will be capturing or compressing video on your computer, you'll need software based on standards such as Microsoft's DirectShow (the successor to Video for Windows and ActiveMovie), Real Network's Real Producer series, or Apple's QuickTime Pro. Players for files produced with these technologies can be downloaded free from the vendors' Web sites.

To play or record video on your multimedia PC (MPC), you need some extra hardware and software:

- Video system software, such as Apple's QuickTime for Windows or Microsoft's Windows Media Player.
- A compression/digitization video adapter that enables you to digitize and play large video files.
- An NTSC-to-VGA adapter that combines TV signals with computer video signals for output to a VCR. Video can come from a variety of sources: TV, VCR, video camera, laserdisc player, or DVD player. When you record an animation file, you can save it in a variety of file formats: AVI (Audio Video Interleave), MOV (Apple QuickTime format), or MPG (MPEG format).

Depending on the video-capture product you use, you have several choices for capturing analog video. The best option is to use component video. Component video uses three RCA-type jacks to carry the luminance (Y) and two chrominance (PR and PB) signals; this type of connector commonly is found on DVD players and high-end conventional and HDTV television sets. However, home-market video capture devices usually don't support component video. A typical professional capture device designed for component video, such as Pinnacle Systems' DC2000DV, retails for about $2,000.

The next best choice, and one that is supported by many home-market video-capture devices, is the S-video (S-VHS) connector. This cable transmits separate signals for color (chroma) and brightness (luma). Otherwise, you must use composite video, which mixes luma and chroma. This results in a lower-quality signal, and the better your signal, the better your video quality will be.

You also can purchase devices that display only NTSC (TV) signals on your computer. The built-in digital movie editing features found in Windows Me and Windows XP, the increasing popularity of computer/TV solutions, and broadband Internet connections make onscreen full-motion video an increasingly common part of the computing experience. Because of the growing importance of onscreen full-motion video, more and more recent CPUs have added features to enhance playback—including MMX and SSE instructions found in the Pentium II, Pentium III, Celeron, and AMD Athlon and Duron and the instruction set found in the Intel Pentium 4's NetBurst microarchitecture and SSE2.

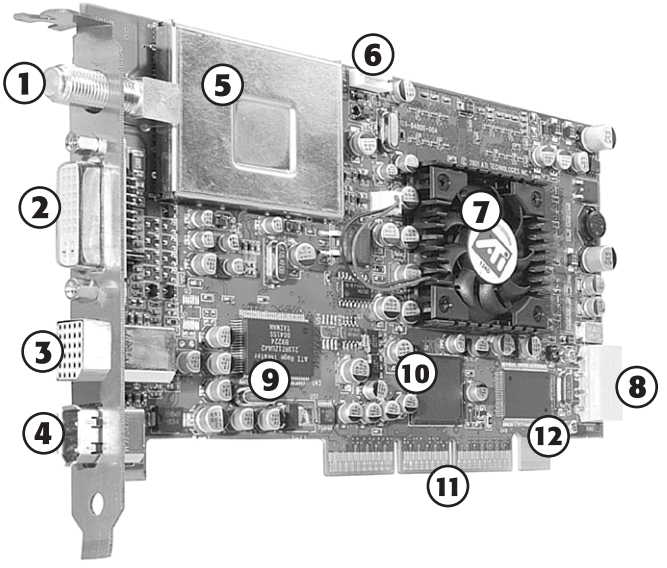

Table 15.15 provides a breakdown of some common video cards and capture devices supporting key features. This table is not inclusive and is meant to serve only as a reference example.

Table 15.15 Video Capture Devices

Device Type	Example
Video card with TV tuner/capture	ATI All-in-Wonder RADEON 8500 DV
TV-tuner/capture breakout box	NVIDIA Personal Cinema (works with GeForce2- and GeForce3-based graphics cards)
PCI TV-tuner and capture card	ATI-TV Wonder
USB port video capture	Dazzle Digital Video Creator series
Parallel port still image capture	Invisco SnapMagic
PCI video capture card	Broadway Pro
IEEE-1394 (FireWire)	AVerMedia AverDV

Figure 15.11 shows a typical video adapter incorporating TV tuner and video-in and video-out features: the ATI All-in-Wonder RADEON 8500 DV. In Figure 15.12 you can see both sides of the included breakout box and the connectors it provides.

Each type of device has advantages and potential disadvantages. Table 15.16 provides a summary that will help you decide which solution is best for you.

1. 75-ohm CATV/antenna connector
2. DVI output for LCD (converts to VGA)
3. A/V out (connects to breakout box)
4. IEEE-1394 port
5. TV tuner
6. Internal audio connector
7. Cooling fan over RADEON 8500 GPU
8. Power connector
9. ATI RAGE Theater chip (analog video capture)
10. AGP 4x bridge chip
11. AGP 4x connector
12. Agere (Lucent) IEEE-1394 chip

Figure 15.11 ATI's All-in-Wonder RADEON 8500DV is a high-end video accelerator with integrated TV tuner and video-capture features. *Photo courtesy of ATI Technologies.*

1. S/PDIF out
2. S-video out
3. Composite out
4. Left audio out
5. Right audio out
6. Left audio in
7. Right audio in
8. Composite in
9. S-video in
10. IEEE-1394 port

Figure 15.12 The ATI All-in-Wonder 8500DV graphics card includes a two-sided breakout box for its video input/output ports. *Photo courtesy of ATI Technologies.*

Table 15.16 Multimedia Device Comparison

Device Type	Pros	Cons
Graphics card with built-in TV tuner and capture	Convenience; single-slot solution	Upgrading requires card replacement.
TV-tuner card	Allows upgrade to existing graphics cards; might be movable to newer models	Might not work with all current chipsets.
Parallel port attachment	Universal usage on desktop or notebook computer; inexpensive	Frame rate limited by speed of port; best for still-image capture.
USB port attachment	Easy installation on late-model USB-equipped computers with Windows 98/Me and Windows 2000/XP	Might not work on Windows 95B OSR 2.x with USB; requires active USB port; not all devices may be compatible with Windows 2000/XP; low bandwidth; not suitable for high-res or full-motion applications.
Dedicated PCI interface card	Fast frame rate for realistic video; works with any graphics card	High resource requirements (IRQ and so on) on some models; requires internal installation.
IEEE-1394 (FireWire) connection to digital video	No conversion from analog to digital needed; all-digital image is very high quality without compression artifacts (blocky areas) in video; fast throughput	Requires IEEE-1394 interface card, IEEE-1394 digital video source; card requires internal installation; some cards don't include capture/editing software; verify that editing software purchased separately works card.

Troubleshooting Video Capture Devices

Table 15.17 provides some advice for troubleshooting problems with video capture devices. Note that IRQ conflicts can be an issue with both parallel port and add-on card devices and that low-bandwidth devices such as parallel port or USB devices might not be capable of supporting full-motion video capture except in a small window.

Table 15.17 Troubleshooting Video Capture Devices

Device Type	Problem	Solutions
Parallel port attachment	Can't detect device, but printers work okay.	Check port settings; device might require IEEE-1284 settings (EPP and ECP); change in BIOS; ensure device is connected directly to port; avoid daisy-chaining devices unless device specifically allows it; check Windows Device Manager for IRQ conflicts.

Table 15.17 Troubleshooting Video Capture Devices

Device Type	Problem	Solutions
TV tuners (built-in graphics card or add-on)	No picture.	Check cabling; set signal source correctly in software; update software
All devices	Video capture is jerky.	Frame rate is too low. Increasing it might require capturing video in a smaller window; use fastest parallel port setting you can; use faster CPU and increase RAM to improve results.
All devices	Video playback has pauses, dropped frames.	Hard disk might be pausing for thermal recalibration; use AV-rated SCSI hard drives or UDMA EIDE drives; install correct busmastering EIDE drivers for motherboard chipset to improve speed.
USB devices	Device can't be detected or doesn't work properly.	Use Windows 98/Me/2000/XP; late versions of Windows 95 have USB drivers, but they often don't work. If you use a USB hub, be sure it's powered.
Interface cards (all types)	Card can't be detected or doesn't work.	Check for IRQ conflicts in Windows Device Manager; consider setting card manually if possible.
IEEE-1394 cards	Card can't be detected or doesn't work.	Make sure power connector is attached to card if card has 4-pin Molex jack. Make sure correct drivers are installed.
All devices	Capture or installation problems.	Use the newest drivers available; check manufacturers' Web site for updates, FAQs, and so on.

Adapter and Display Troubleshooting

Solving most graphics adapter and monitor problems is fairly simple, although costly, because replacing the adapter or display is the normal procedure. However, before you take this step, be sure that you have exhausted all your other options. One embarrassingly obvious fix to monitor display problems that is often overlooked by many users is to adjust the controls on the monitor, such as the contrast and brightness. Although most monitors today have a control panel on the front of the unit, other adjustments might be possible as well.

Some NEC monitors, for example, have a focus adjustment screw on the left side of the unit. Because the screw is deep inside the case, the only evidence of its existence is a hole in the plastic grillwork on top of it. To adjust the monitor's focus, you must stick a long-shanked screwdriver about 2" into the hole and feel around for the screw head. This type of adjustment can save you both an expensive repair bill and the humiliation of being ridiculed by the repair technician. Always examine the monitor case, documentation, and manufacturer's Web site or other online services for the locations of adjustment controls.

A defective or dysfunctional adapter or display usually is replaced as a single unit rather than being repaired. Except for specialized CAD or graphics workstation–oriented adapters, virtually all of today's adapters cost more to service than to replace, and the documentation required to service the hardware properly is not always available. You usually can't get schematic diagrams, parts lists, wiring diagrams, and other documents for most adapters or monitors. Also, virtually all adapters now are constructed with surface-mount technology that requires a substantial investment in a rework station before you can remove and replace these components by hand. You can't use a $25 pencil-type soldering iron on these boards!

Servicing monitors is a slightly different proposition. Although a display often is replaced as a whole unit, some displays—particularly 20" or larger CRTs or most LCD panels—might be cheaper to repair than to replace. If you decide to repair the monitor, your best bet is to either contact the company from which you purchased the display or contact one of the companies that specializes in monitor depot repair. If your monitor has a 15" diagonal measurement or less, consider replacing it with a unit that is 17" or larger because repair costs on small monitors come close to replacement costs and large monitors aren't much more expensive these days.

Depot repair means you send in your display to repair specialists who either fix your particular unit or return an identical unit they have already repaired. This usually is accomplished for a flat-rate fee; in other words, the price is the same no matter what they have done to repair your actual unit.

Because you usually get a different (but identical) unit in return, they can ship out your repaired display immediately on receiving the one you sent in, or even in advance in some cases. This way, you have the least amount of downtime and can receive the repaired display as quickly as possible. In some cases, if your particular monitor is unique or one they don't have in stock, you must wait while they repair your specific unit.

Troubleshooting a failed monitor is relatively simple. If your display goes out, for example, a swap with another monitor can confirm that the display is the problem. If the problem disappears when you change the display, the problem is almost certainly in the original display or the cable; if the problem remains, it is likely in the video adapter or PC itself.

Many of the better quality, late-model monitors have built-in self-diagnostic circuitry. Check your monitor's manual for details. Using this feature, if available, can help you determine whether the problem is really in the monitor, in a cable, or somewhere else in the system. If self diagnostics produce an image onscreen, look to other parts of the video subsystem for your problem.

The monitor cable can sometimes be the source of display problems. A bent pin in the DB-15 connector that plugs into the video adapter can prevent the monitor from displaying images, or it can cause color shifts. Most of the time, you can repair the connector by carefully straightening the bent pin with sharp-nosed pliers.

If the pin breaks off or the connector is otherwise damaged, you can sometimes replace the monitor cable. Some monitor manufacturers use cables that disconnect from the monitor and video adapter, whereas others are permanently connected. Depending on the type of connector the device uses at the monitor end, you might have to contact the manufacturer for a replacement.

If you narrow down the problem to the display, consult the documentation that came with the monitor or call the manufacturer for the location of the nearest factory repair depot. Third-party depot repair service companies are also available that can repair most displays (if they are no longer covered by a warranty); their prices often are much lower than factory service. Check the Vendor List on the DVD for several companies that do depot repair of computer monitors and displays.

Caution

You should never attempt to repair a CRT monitor yourself. Touching the wrong component can be fatal. The display circuits can hold extremely high voltages for hours, days, or even weeks after the power is shut off. A qualified service person should discharge the cathode ray tube and power capacitors before proceeding.

For most displays, you are limited to making simple adjustments. For color displays, the adjustments can be quite formidable if you lack experience. Even factory service technicians often lack proper documentation and service information for newer models; they usually exchange your unit for another and repair the defective one later. Never buy a display for which no local factory repair depot is available.

If you have a problem with a display or an adapter, it pays to call the manufacturer, who might know about the problem and make repairs available. Sometimes, when manufacturers encounter numerous problems with a product, they might offer free repair, replacements, or another generous offer that you would never know about if you did not call.

Remember, also, that many of the problems you might encounter with modern video adapters and displays are related to the drivers that control these devices rather than to the hardware. Be sure you have the latest and proper drivers before you attempt to have the hardware repaired; a solution might already be available.

Troubleshooting Monitors

Problem

No picture.

Solution

If the LED on the front of the monitor is yellow or flashing green, the monitor is in power-saving mode. Move the mouse or press Alt+Tab on the keyboard and wait up to 1 minute to wake up the system if the system is turned on.

If the LED on the front of the monitor is green, the monitor is in normal mode (receiving a signal), but the brightness and contrast are set incorrectly; adjust them.

If no lights are lit on the monitor, check the power and power switch. Check the surge protector or power director to ensure that power is going to the monitor. Replace the power cord with a known-working spare if necessary. Retest. Replace the monitor with a known-working spare to ensure that the monitor is the problem.

Check data cables at the monitor and video card end.

Problem

Jittery picture quality.

Solution

LCD monitors. Use display-adjustment software or onscreen menus to reduce or eliminate pixel jitter and pixel swim.

All monitors. Check cables for tightness at the video card and the monitor (if removable):

- Remove the extender cable and retest with the monitor plugged directly into the video card. If the extended cable is bad, replace it.

- Check the cables for damage; replace as needed.
- If problems are intermittent, check for interference. (Microwave ovens near monitors can cause severe picture distortion when turned on.)

CRT monitors. Check refresh-rate settings; reduce them until acceptable picture quality is achieved:

- Use onscreen picture adjustments until an acceptable picture quality is achieved.
- If problems are intermittent and can be "fixed" by waiting or gently tapping the side of the monitor, the monitor power supply is probably bad or has loose connections internally. Service or replace the monitor.

Troubleshooting Video Cards and Drivers

Problem

Display works in DOS but not in Windows.

Solution

If you have an acceptable picture quality in MS-DOS mode (system boot) but no picture in Windows, most likely you have an incorrect or corrupted video driver installed in Windows. Boot Windows 9x/Me in Safe Mode (which uses a VGA driver), boot Windows 2000/XP in Enable VGA mode, or install the VGA driver and restart Windows. If Safe Mode or VGA Mode works, get the correct driver for the video card and reinstall.

If you have overclocked your card with a manufacturer-supplied or third-party utility, you might have set the speed too high. Restart the system in Safe Mode, and reset the card to run at its default speed.

Problem

Can't replace built-in video card with add-on PCI video card.

Solution

Check with the video card and system vendor for a list of acceptable replacement video cards. Try another video card with a different chipset. Check the BIOS or motherboard for jumper or configuration settings to disable built-in video. Place the add-on card in a different PCI slot.

Problem

Can't select desired color depth and resolution combination.

Solution

Verify that the card is properly identified in Windows and that the card's memory is working properly. Use diagnostic software provided by the video card or chipset maker to test the card's memory. If the hardware is working properly, check for new drivers.

Problem

Can't select desired refresh rate.

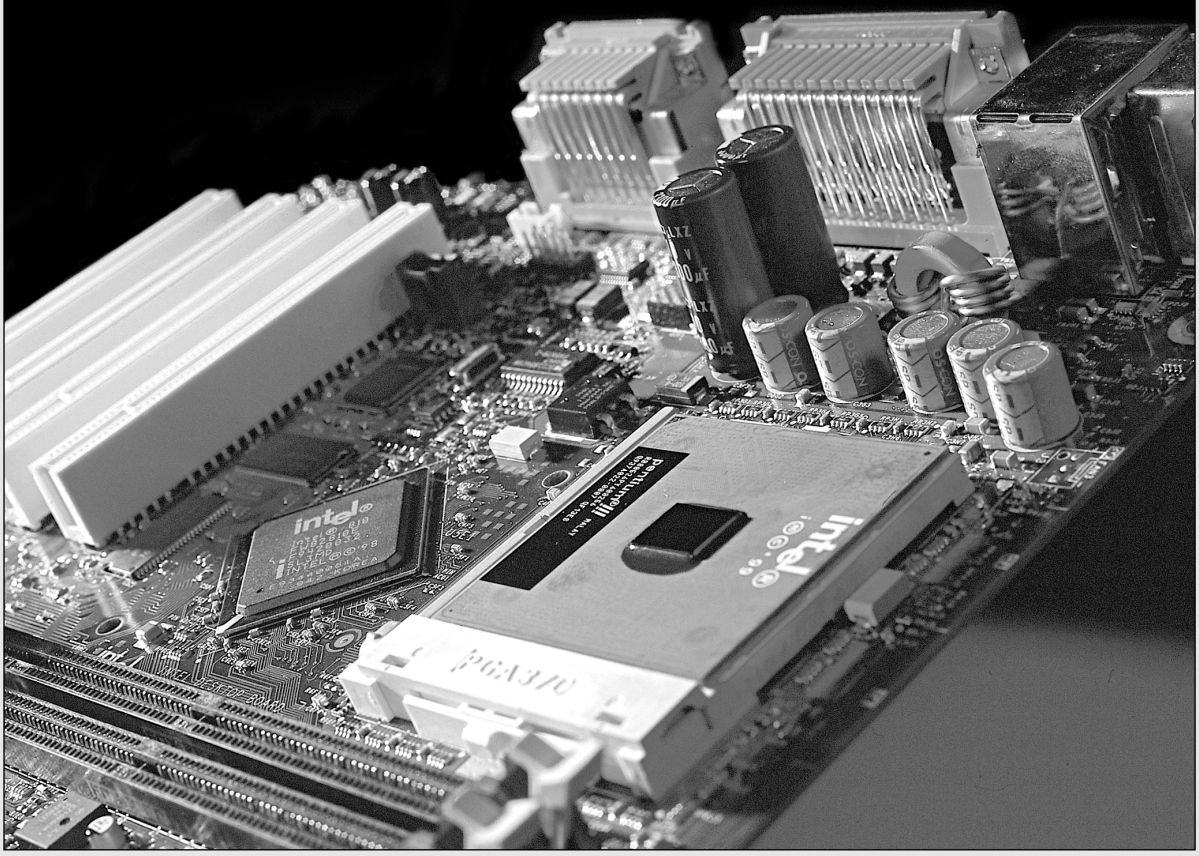
Solution

Verify that the card and monitor are properly identified in Windows. Obtain updated drivers for the card and monitor.

DisplayMate

DisplayMate is a unique diagnostic and testing program designed to thoroughly test your video adapter and display. It is somewhat unique in that most conventional PC hardware diagnostics programs do not emphasize video testing the way this program does.

I find it useful not only in testing whether a video adapter is functioning properly, but also in examining video displays. You easily can test the image quality of a display, which allows you to make focus, centering, brightness and contrast, color level, and other adjustments much more accurately than before. If you are purchasing a new monitor, you can use the program to evaluate the sharpness and linearity of the display and to provide a consistent way of checking each monitor you are considering. If you use projection systems for presentations—as I do in my PC hardware seminars—you will find it invaluable for setting up and adjusting the projector.



DisplayMate also can test a video adapter thoroughly. It sets the video circuits into each possible video mode so you can test all its capabilities. It even helps you determine the performance level of your card, both with respect to resolution and colors as well as speed. You can then use the program to benchmark the performance of the display, which enables you to compare one type of video adapter system to another.

See the Vendor List on the CD for more information on DisplayMate (formerly Sonera) Technologies, the manufacturer and distributor of DisplayMate.

Some video-card vendors supply a special version of DisplayMate for use in diagnostics testing.

CHAPTER 16

Audio Hardware

Since the first edition of this book was published in 1988, a lot has happened to audio hardware. Although rudimentary audio capabilities were part of the original IBM PC of 1981 and its many successors, audio was used on early computers for troubleshooting rather than for creative tasks. Computers used beeps for little other than to signal problems such as a full keyboard buffer or errors during the power on self test (POST) sequence. The Macintosh, first introduced in 1984, included high-quality audio capabilities in its built-in hardware, but PCs did not gain comparable audio capabilities until the first add-on sound cards from companies such as Ad Lib and Creative Labs were developed in the late 1980s.

Thanks to competition among many companies, we now enjoy widely supported de facto hardware and software standards for audio. Audio hardware has gone from being an expensive, exotic add-on to being an assumed part of virtually any system configuration.

Today's PC audio hardware might take one of the following forms:

- An audio adapter on a PCI expansion card that you install into a bus slot in the computer
- A sound chip on the motherboard from companies such as Crystal, Analog Devices, Sigmatel, ESS, or others
- Hardware that's integrated into the motherboard's main chipset, as with some of the most recent chipsets for computers developed by Intel, SiS, NVIDIA, and VIA Technologies

Regardless of their location, the audio features use jacks for speakers and a microphone. In addition, almost all of them provide dedicated jacks for analog joysticks and MIDI hardware, although some of the latest models rely on USB port connections for joysticks. As you will see later in this chapter, many mid-range and high-end audio adapters also support sophisticated digital audio input and output. On the software side, the audio adapter requires the support of a driver that you install either directly from an application or in your computer's operating system. This chapter focuses on the audio products found in today's PCs, their uses, and how you install and operate them.

Early PC Audio Adapters

When the first audio adapters were introduced in the late 1980s by companies such as AdLib, Roland, and Creative Labs, they were aimed squarely at a gaming audience. The 1989-vintage Creative Labs Game Blaster card cost more than $100 but supported only a handful of games. And, because no sound standards existed at the time, the sound card you selected could turn out to be useless with some games if the game manufacturer chose not to specifically support it.

Note

About the same time as the release of the Game Blaster, hardware supporting the Musical Instrument Digital Interface (MIDI) became available for the PC. At this time, however, such hardware was used only in very specialized recording applications. As MIDI support became a more common feature in musical instruments, though, it also became a more affordable PC add-on.

The Game Blaster was soon replaced by the Sound Blaster, which was compatible with the AdLib sound card and the Creative Labs Game Blaster card, enabling it to support games that specified one sound card or the other. The Sound Blaster included a built-in microphone jack, stereo output, and a MIDI port for connecting the PC to a synthesizer or other electronic musical instrument. This established a baseline of features that would be supported by virtually all other sound cards and onboard sound features up to the present. Finally, the audio adapter had the potential for uses other than games. The follow-up Sound Blaster Pro featured improved sound when compared to the original Sound Blaster. The Sound Blaster Pro and its successors eventually triumphed over earlier rivals to become de facto standards for PC sound reproduction.

Unlike de jure standards such as the IEEE-1394 port, which is an official standard of the IEEE organization, de facto standards are those that develop informally due to the widespread acceptance of the market leader's products in a particular segment of the marketplace.

Limitations of Sound Blaster Pro Compatibility

Through the mid-1990s, while MS-DOS was the standard gaming platform, many users of non-Creative Labs sound cards struggled with the limitations of their hardware's imperfect emulation of the Sound Blaster Pro. Ideally, a Sound Blaster Pro–compatible card would be capable of using the same IRQ, DMA, and I/O port addresses as a Sound Blaster Pro card from Creative Labs and would be used by an application program in the same way as an actual Sound Blaster Pro. Unfortunately, some cards required two separate sets of hardware resources, using one set of IRQ, DMA, and I/O port addresses for native mode and a second set for Sound Blaster Pro compatibility. Others worked well within Windows or within an MS-DOS session running with Windows in the background but required the user to install a DOS-based Terminate and Stay Resident (TSR) driver program to work in MS-DOS itself.

If you've never needed to configure a game for a particular sound card, you're probably playing all 32-bit Windows games. Windows applications use the operating system's drivers to interface with hardware, relieving the software developer from needing to write different code for different sound cards, 3D graphics cards, and so on. For 3D sound and gaming graphics, Microsoft Windows uses a technology called DirectX, which was first introduced in December 1995.

DirectX and Audio Adapters

Microsoft's DirectX is a series of application program interfaces (APIs) that sit between multimedia applications and hardware. Unlike MS-DOS applications that required developers to develop direct hardware support for numerous models and brands of audio cards, video cards, and game controllers, Windows uses DirectX to "talk" to hardware in a more direct manner than normal Windows drivers do. This improves program performance and frees the software developer from the need to change the program to work with different devices. Instead, a game developer must work with only the DirectX sound engine, DirectX 3D renderer, and DirectX modem or network interface routines.

▶▶ For more information about DirectX and sound hardware, see "3D Audio," p. 945.

Thanks to DirectX, sound card and chipset developers are assured that their products will work with recent and current versions of Windows. However, if you still enjoy playing MS-DOS–based games, current audio adapters, chipsets, and integrated audio solutions still might present a compatibility challenge to you because of fundamental hardware differences between the ISA expansion slots used by classic Creative Labs and other sound cards and PCI slots, chipsets, and integrated audio.

▶▶ For more information about using PCI sound hardware with MS-DOS games, see "Legacy (MS-DOS) Game Support Issues," p. 935.

PC Multimedia History

Virtually every computer on the market today is equipped with some type of audio adapter and a CD-ROM or CD-ROM–compatible drive such as a CD-RW or DVD drive. Computers equipped with an audio adapter and a CD-ROM–compatible drive are often referred to as *multimedia* PCs after the old MPC-1, MPC-2, and MPC-3 standards that were used to rate early multimedia computers. Since 1996, all computers with onboard sound and a CD-ROM or compatible optical drive have exceeded MPC-3 standards by increasingly huge margins.

Note

For more information about the MPC series of multimedia standards, see the section "Multimedia" in Chapter 20 of *Upgrading and Repairing PCs, 11th Edition*, available in electronic form on the DVD-ROM accompanying this book.

Suggested Multimedia Minimums

The following list of specifications gives you a comfortable multimedia experience today; in fact, even the lowest-cost computer currently available at retail should meet or exceed these specifications:

- CPU: 700MHz Pentium III, Celeron, Athlon, Duron, or other Pentium-class processor
- RAM: 128MB
- Hard disk: 20GB
- CD-ROM drive: 24X read or DVD-ROM drive—10X read (equals about 27X CD-ROM read rate)
- Audio sampling rate: 16-bit
- VGA video resolution: 1024×768
- Color depth: 16.8 million colors (24-bit color)
- I/O devices: MIDI and USB
- Minimum operating system: Windows 98, Windows Me, or Windows XP Home Edition

Note that although speakers or headphones are technically not a part of the MPC specification or the updated list, they are certainly required for sound reproduction. Additionally, sound input for voice recording or voice control also requires a microphone. Keep in mind that many prebuilt PCs include low-cost powered or unpowered speakers that you will likely want to replace with speakers or headphones that provide the mixture of size, frequency response, and overall sound quality you need.

Because the MPC specifications reflect multimedia's past, users who want to know what comes next need to turn somewhere else for guidance. Microsoft and Intel jointly manage the PC Design Guide Web site at `http://www.pcdesguide.org`, where the older PC99 and current PC2001 specifications and addenda can be read and reviewed. These standards are widely followed by the industry and point the way to many other enhancements for audio hardware and software in the Windows environment.

Although virtually every computer is a "multimedia PC" today, the features of the audio adapter in your system will help determine how satisfied you will be with the wide range of specialized uses for multimedia-equipped systems.

Later in this chapter, you learn more about the features you need to specify to ensure your audio adapter—regardless of type—is ready to work for you.

Audio Adapter Features

To make an intelligent purchasing decision, you should be aware of some audio adapter basic components and the features they provide, as well as the advanced features you can get on better audio adapters. The following sections discuss the features you should consider while evaluating audio adapters for your PC.

Basic Connectors

Most audio adapters have the same basic connectors. These 1/8" minijack connectors provide the means of passing sound signals from the adapter to speakers, headphones, and stereo systems, and of receiving sound from a microphone, CD player, tape player, or stereo. The four types of connectors your audio adapter should have at a minimum are shown in Figure 16.1.

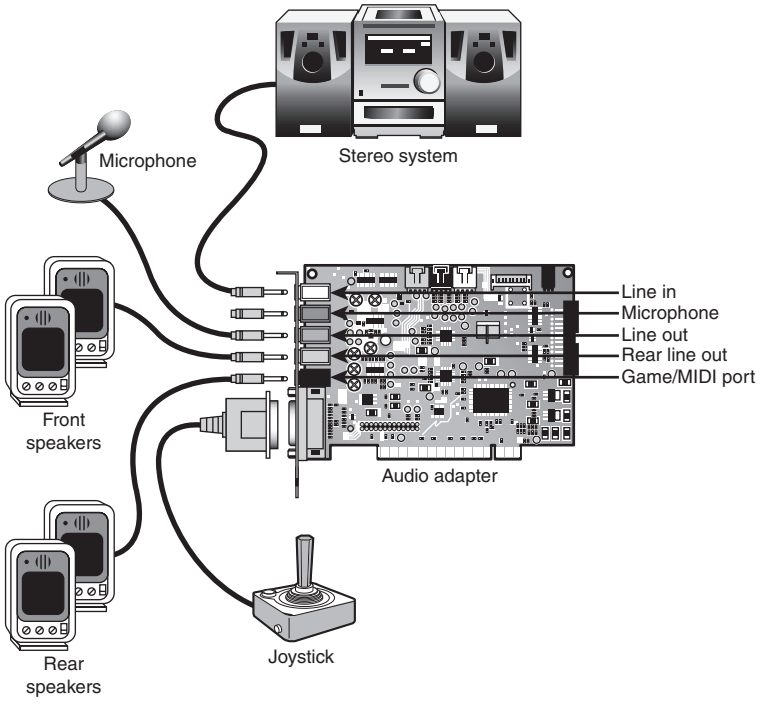


Figure 16.1 The basic input and output connectors that most audio adapters have in common.

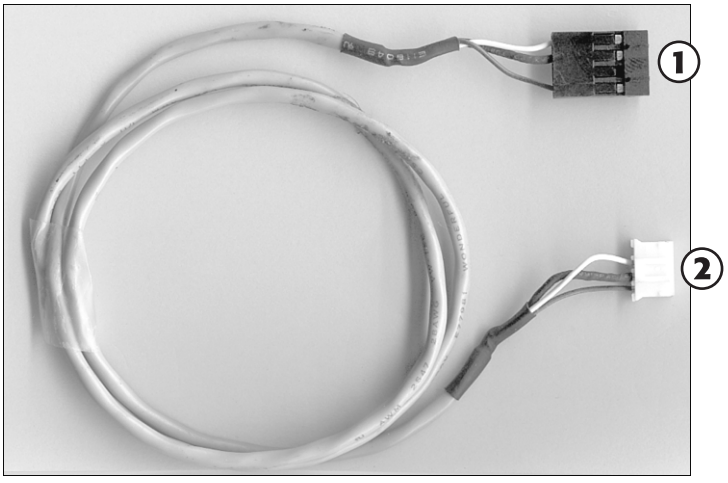
The jacks shown in Figure 16.1 are usually labeled, but when setting up a computer on or under a desk, the labels on the back of the PC can be difficult to see. One of the most common reasons a PC fails to produce any sound is that the speakers are plugged into the wrong socket. To avoid this problem, many consumer-oriented audio cards color-code the jacks according to specifications found in the PC99 Design Guide (see `http://www.pcdesguide.org/documents/pc99icons.htm`). The color-coding can vary on some audio adapters (or not be present at all). Regardless, the basic set of connections included on most audio cards is as follows:

- *Stereo line, or audio, out connector (lime green).* The line-out connector is used to send sound signals from the audio adapter to a device outside the computer. You can hook up the cables from the line-out connector to stereo speakers, a headphone set, or your stereo system. If you hook up the PC to your stereo system, you can have amplified sound.
- *Stereo line, or audio, in connector (light blue).* With the line-in connector, you can record or mix sound signals from an external source, such as a stereo system or VCR, to the computer's hard disk.
- *Rear out or speaker/headphone connector (no standard color).* Older sound cards often provided an amplified jack supplying up to 4 watts of power for use with unpowered speakers or headphones along with the line-out connector. Today, you are more likely to find this jack used for rear speakers in four-speaker setups. The rear out jack often is disabled by default; check your audio adapter properties or setup program to see whether you need to enable this port when you connect rear speakers.

Note

If you have only a single speaker/line-out connector, you must carefully adjust your mixer volume control and the volume control on your amplified speakers to find the best quality sound. Don't use powered speakers with an already-amplified sound if you can avoid it.



- *Microphone, or mono, in connector (pink).* The mono-in connector is used to connect a microphone for recording your voice or other sounds to disk. This microphone jack records in mono—not in stereo—and is therefore not suitable for high-quality music recordings. Many audio adapters cards use Automatic Gain Control (AGC) to improve recordings. This feature adjusts the recording levels on-the-fly. A 600ohm–10,000ohm dynamic or condenser microphone works best with this jack. Some inexpensive audio adapters use the line-in connector instead of a separate microphone jack.
- *Joystick connector (gold).* The joystick connector is a 15-pin, D-shaped connector that can connect to any standard joystick or game controller. Sometimes the joystick port can accommodate two joysticks if you purchase an optional Y-adapter. Many computers already contain a joystick port as part of a multifunction I/O circuit on the motherboard or an expansion card. If this is the case, you must note which port your operating system or application is configured to use when connecting the game controller. Some of the latest sound cards and systems with onboard sound omit this connector because most recent game controllers support USB connectors.
- *MIDI connector (gold).* Audio adapters typically use the same joystick port as their MIDI connector. Two of the pins in the connector are designed to carry signals to and from a MIDI device, such as an electronic keyboard. In most cases, you must purchase a separate MIDI connector from the audio adapter manufacturer that plugs into the joystick port and contains the two round, 5-pin DIN connectors used by MIDI devices, plus a connector for a joystick. However, high-end sound cards might use 5-pin MIDI ports connected to a daughtercard or a breakout box (see Figure 16.3, later in this chapter). Because their signals use separate pins, you can connect the joystick and a MIDI device at the same time. You need this connector only if you plan to connect your PC to external MIDI devices. You can still play the MIDI files found on many Web sites by using the audio adapter's internal synthesizer.

Note

Some recent systems with onboard audio lack the joystick/MIDI connector, but you can use digital game controllers that feature a game port or USB connector to attach your game controllers to the USB port. And, as mentioned earlier, you can attach MIDI devices through the same USB connector with a suitable interface box.

In addition to the external connections, most sound cards feature at least one (and possibly multiple) internal CD-audio connectors. Most audio adapters have an internal 4-pin connector you can use to plug an internal CD-ROM drive directly into the audio adapter, using a small round cable (see Figure 16.2). This connection enables you to channel audio signals from the CD-ROM directly to the audio adapter, so you can play the sound through the computer's speakers.

This connector does not carry data from the CD-ROM to the system bus; it provides the CD-ROM drive only with direct audio access to the speakers. If you install a new CD-ROM, CD-RW, or DVD drive or a new sound card, be sure you attach this CD-audio cable between the card and the drive; otherwise, you will be unable to play music CDs or hear some game audio in most cases.

1. Connects to CD-ROM drive
2. Connects to sound card

Figure 16.2 A typical CD-ROM analog audio cable.

Connectors for Advanced Features

Many of the newest sound cards are designed for advanced gaming, DVD audio playback, and sound production uses and have additional connectors to support these uses, such as the following:

- *MIDI in and MIDI out.* Some advanced sound cards don't require you to convert the game port (joystick port) to MIDI interfacing by offering these ports on a separate external connector. This permits you to use a joystick and have an external MIDI device connected at the same time. Typical location: external device.
- *SPDIF (also called SP/DIF) in and SPDIF out.* The Sony/Philips Digital Interface receives digital audio signals directly from compatible devices without converting them to analog format first. Typical location: external device. (SPDIF interfaces are also referred to by some vendors as "Dolby Digital" interfaces.)

Note

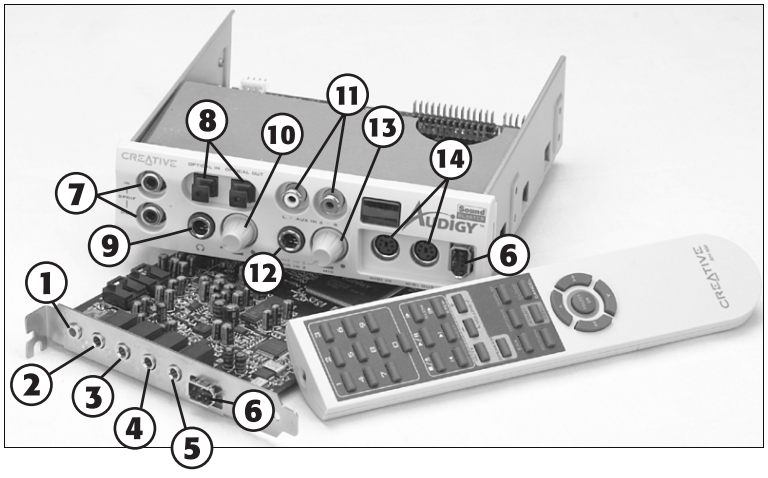
SPDIF connectors use cables with the standard RCA jack connector but are designed to work specifically at an impedance of 75ohms—the same as composite video cables. Thus, you can use RCA-jack composite video cables with your SPDIF connectors. Although audio cables are also equipped with RCA jacks, their impedance is different, making them a less desirable choice.

- *CD SPDIF.* Connects compatible CD-ROM drives with SPDIF interfacing to the digital input of the sound card. Typical location: side of audio card.
- *TAD in.* Connects internal modems with Telephone Answering Device support to the sound card for sound processing of voice messages. Typical location: side of audio card.
- *Digital DIN out.* This supports multispeaker digital speaker systems, such as those produced by Cambridge for use with the SoundBlaster Live! series. Typical location: external device.

- *Aux in.* Provides input for other sound sources, such as a TV tuner card. Typical location: side of audio card.
- *I2S in.* This enables the sound card to accept digital audio input from an external source, such as two-channel decoded AC-3 from DVD decoders and MPEG-2 Zoom Video. Typical location: side of audio card.
- *USB port.* This enables the sound card to connect to USB speakers, game controllers, and other types of USB devices. The Hercules Game Theater XP, the first sound card with built-in USB ports, supports USB 1.1 only. However, improved models might support USB 2.0 in the future. Typical location: external device.
- *IEEE-1394.* This enables the sound card to connect to IEEE-1394-compatible DV camcorders, scanners, hard drives, and other devices. The Sound Blaster Audigy's SB1394 port supports both standard IEEE-1394 devices and devices that meet Creative Labs' more rigid SB1394 standard. Typical location: card bracket or external device.

Note

Creative Labs tests IEEE-1394 drives and devices to determine their data transfer performance, hot-swap support, and power management features. Devices that pass Creative Labs' tests are called SB1394 Certified when the certification process is complete or SB1394 Compatible until the certification process is complete. The Audigy series' SB1394 port also supports standard IEEE-1394 devices.



Sometimes, these additional connectors are found on the card itself, or sometimes they are attached to an internal or external breakout box, daughtercard, or external rack. For example, the Sound Blaster Audigy Platinum, Platinum EX, and Hercules Game Theater are two-piece units. The Audigy audio adapter itself plugs into a PCI slot, but some additional connectors are routed to an internal breakout box on the Platinum, which fits into an unused 5 1/4" drive bay (see Figure 16.3). The top-of-the-line Platinum EX uses an external breakout box with the same connection options. Both models feature a remote control, also visible in Figure 16.3. The Hercules Game Theater also features an external breakout box, which Hercules refers to as an audio rack.

Figure 16.4 shows Voyetra Turtle Beach's Santa Cruz audio adapter card with the internal connectors common on today's 3D sound cards.

Adding Advanced Sound Features Without Replacing Onboard Audio

Traditionally, audio card upgrades have been designed specifically for users of desktop computers, leaving the growing number of notebook computer users out in the cold if they decided that the barebones features of their integrated audio weren't sufficient. However, the Creative Labs Sound Blaster Extigy allows both notebook and desktop computer users to add advanced I/O features without opening the system.

The front and rear panels of the Sound Blaster Extigy are shown in Figures 16.5 and 16.6, respectively. The Extigy connects to any system that has a USB 1.x or 2.x port, enabling the Extigy to be used on virtually any recent PC with any manufacturer's sound chip, sound card, or audio integrated chipset.

1. Analog/digital out
2. Line in
3. Microphone in
4. Front line out
5. Rear line out
6. SB1394 ports (one each on the card bracket and on the Audigy drive)
7. SPDIF in/out
8. Optical in/out
9. Headphone out
10. Volume control for headphone out
11. Left/right Aux in
12. Line in
13. Volume control for line in
14. MIDI in/out

Figure 16.3 The Sound Blaster Audigy Platinum comes with the Audigy Drive internal, front-panel breakout box to support the Audigy's many features.

Volume Control

With virtually all recent sound cards, the volume is controlled through a Windows Control Panel speaker icon that can also be found in the system tray (near the onscreen clock). If you're switching from a bare-bones stereo sound card to a more sophisticated one featuring Dolby Digital 5.1 output or input, you will need to use the mixing options in the volume control to select the proper sources and appropriate volume levels for incoming and outgoing audio connected to the card or a breakout box. Keep in mind that if you are sending sound to an external audio receiver, you will need to adjust the volume on that device as well.

By contrast, some older audio adapters included a thumbwheel volume control next to the input/output jacks. The volume wheel can be troublesome; if you aren't aware of its existence and it is turned all the way down, you might be puzzled by the adapter's failure to produce sufficient sound.

If the PC speakers are amplified but you aren't hearing any sound, remember to check that the power is on, the volume control on the speakers is turned up, and the correct speakers are selected and properly connected.

MIDI Support Features

At one time, when evaluating audio adapters, you had to decide whether to buy a monophonic or stereophonic card. Today, all audio adapters are stereophonic and can play music using the MIDI standard, which plays scores using either synthesized instruments or digital samples stored on the audio adapter or in RAM.

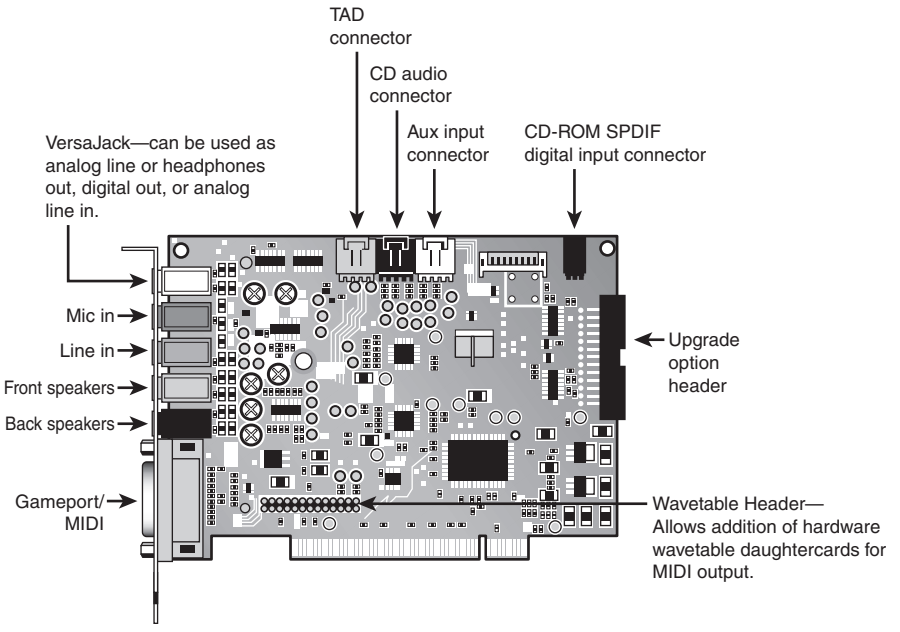


Figure 16.4 Voyetra Turtle Beach's Santa Cruz is a typical example of an advanced 3D sound card.

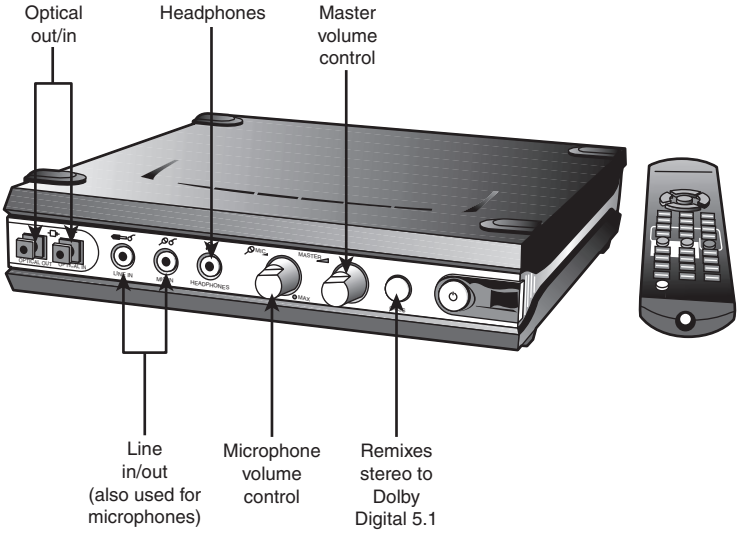

Figure 16.5 The Sound Blaster Extigy expands bare-bones onboard audio by adding advanced I/O features similar to those found on the Sound Blaster Audigy series. *Photo courtesy of Creative Labs.*

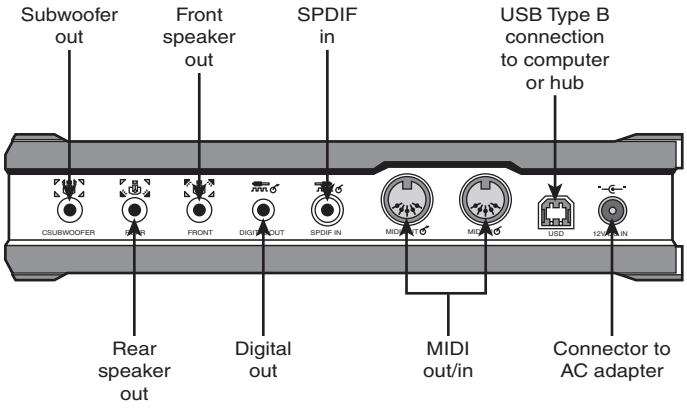

Figure 16.6 The rear panel of the Sound Blaster Extigy adds ports for stereo, rear, and subwoofer speakers, as well as the USB input to the computer, MIDI keyboard/device support, and digital input/output.

Stereophonic cards produce many voices concurrently and from two sources. A voice is a single sound produced by the adapter. A string quartet uses four voices, one for each instrument. On the other hand, a polyphonic instrument, such as a piano, requires one voice for each note of a chord. Thus, fully reproducing the capabilities of a pianist requires 10 voices—one for each finger. The more voices an audio adapter is capable of producing, the better the sound fidelity. The best audio adapters on the market today can produce up to 1,024 simultaneous voices.

Early audio adapters used FM synthesis for MIDI support; the Yamaha OPL2 (YM3812) featured 11 voices, whereas the OPL3 (YMF262) featured 20 voices and stereophonic sound. However, virtually all audio adapters today use recorded samples for MIDI support; audio adapters using this feature are referred to as *wavetable* adapters.

Wavetable audio adapters use digital recordings of real instruments and sound effects instead of imitations generated by an FM chip. When you hear a trumpet in a MIDI score played on a wavetable sound card, you hear the sound of an actual trumpet, not a synthetic imitation of a trumpet. The first cards featuring wavetable support stored 1MB of sound clips embedded in ROM chips on the card. However, with the widespread use of the high-speed PCI bus for sound cards and large amounts of RAM in computers, most soundcards now use a so-called "soft wavetable" approach, loading 2MB–8MB of sampled musical instruments into the computer's RAM.

Note

Some vendors, such as Creative Labs, Voyetra Turtle Beach, and Yamaha, have produced daughtercards to add wavetable support to FM-synthesis or soft wavetable sound cards. Most of these products have been discontinued due to the popularity and high quality of PCI audio adapters with large sample sets of soft wavetable sounds.

While early games supported only digitized audio samples (because most early sound cards had very poor MIDI support), late DOS games such as DOOM began to exploit the widespread wavetable-based MIDI support found on most mid-1990s and more recent sound cards. With all current sound hardware supporting wavetable MIDI and the improvements in DirectX 8.x and above for MIDI support,

MIDI sound has become far more prevalent for game soundtracks. Many Web sites also offer instructions for patching existing games to allow MIDI support. Whether you play the latest games or like music, good MIDI performance is likely to be important to you.

The most important factor for high-performance MIDI is the number of hardware voices. Even the best sound cards, such as Creative Labs' Sound Blaster Audigy series, support only 64 voices in hardware; the remainder of the voices required by a MIDI soundtrack must come from software. If your sound card supports only 32 MIDI voices in hardware or uses software synthesis only, consider replacing it with a newer model. Many of the models currently on the market support more than 500 simultaneous voices and 64 hardware voices for under $100.

Data Compression

Virtually all audio adapters on the market today can easily produce CD-quality audio, which is sampled at 44.1KHz. At this rate, recorded files (even of your own voice) can consume more than 10MB for every minute of recording. To counter this demand for disk space, many audio adapters include their own data-compression capability. For example, the Sound Blaster series includes on-the-fly compression of sound files in ratios of 2:1, 3:1, and 4:1.

Most manufacturers of audio adapters use an algorithm called Adaptive Differential Pulse Code Modulation (ADPCM) compression (it's also called IMA-ADPCM), which was developed by the Interactive Multimedia Association (IMA) to reduce file size by more than 50%. IMA-ADPCM compresses 16-bit linear samples down to 4 bits per sample. However, a simple fact of audio technology is that when you use such compression, you lose sound quality. Unfortunately, no standard exists for the use of ADPCM. For example, although both Apple and Microsoft support IMA-ADPCM compression, they implement it in different ways. Apple's standard AIFF and Microsoft's standard WAV file formats are incompatible with each other unless you use a media player that can play both.

When you install an audio adapter, several codecs (programs that perform compression and decompression) are installed. Typically, some form of ADPCM is installed along with many others. To see which codecs are available on your system, open the Windows Control Panel and open the Multimedia icon (Windows 9x), the Sounds and Multimedia icon (Windows 2000), or the Sounds and Audio Devices icon (Windows XP). In Windows 9x, click the Devices tab followed by the plus sign next to Audio Compression to see the installed codecs. In Windows 2000 and Windows XP, click the Hardware tab, followed by Audio Codecs and Properties. If you create your own recorded audio for use on another computer, both computers must use the same codec. You can select which codec you want to use for recording sounds with most programs, including the Windows Sound Recorder.

The most popular compression standard is the Motion Pictures Experts Group (MPEG) standard, which works with both audio and video compression and is gaining support in the non-PC world from products such as DVD players. MPEG by itself provides a potential compression ratio of 30:1, and largely because of this, full-motion-video MPEG DVD and CD-ROM titles are now available. The popular MP3 sound compression scheme is an MPEG format, and it can be played back on recent versions of the Windows Media Player, as well as by various other audio player programs and devices.

Multipurpose Digital Signal Processors

Many audio adapters use digital signal processors (DSPs) to add intelligence to the adapter, freeing the system processor from work-intensive tasks, such as filtering noise from recordings or compressing audio on-the-fly.

The Sound Blaster Audigy's E-MU10K2 programmable DSP, for example, supports hardware sound acceleration needed by the latest version of Microsoft DirectX/DirectSound 3D, which enables multiple sounds to be played at the same time to synchronize with the onscreen action in a video game.

The DSP can be upgraded with software downloads to accommodate more simultaneous audio streams. The widespread use of DSPs in better-quality audio adapters enables you to upgrade them through software instead of the time-consuming, expensive process of physical replacement. For additional examples of DSPs, see the section "Who's Who in Audio," later in this chapter.

Sound Drivers

As with many PC components, a software driver provides a vital link between an audio adapter and the application or operating system that uses it. Operating systems such as Windows 9x/Me and Windows 2000/XP include a large library of drivers for most of the audio adapters on the market (Windows NT 4.0 also supports some sound hardware but not as much as other versions of Windows). In most cases, these drivers are written by the manufacturer of the audio adapter and distributed only by Microsoft. You might find that the drivers that ship with the adapter are more recent than those included with the operating system. Although traditionally the best place to find the most recent drivers for a piece of hardware has been the manufacturer's own Web site or other online service, Windows Me, 2000, and XP prefer digitally signed drivers that have been certified by the Microsoft Hardware Quality Labs. You might find these drivers available at the vendor's own Web site, but you can also download and install them automatically through Windows Update.

Any DOS applications you might still use do not typically include as wide a range of driver support as an operating system, but you should find that most games and other programs support the Sound Blaster adapters. If you are careful to buy an adapter that is compatible with Sound Blaster, you should have no trouble finding driver support for all your applications. Older ISA Sound Blaster cards provided hardware support for DOS games, but recent models (including the latest Sound Blaster Audigy series), as well as most comparable sound cards, require you to run software drivers to obtain Sound Blaster compatibility for DOS games. This software must be run before the game starts.

If your game program locks up when you try to detect the sound card during configuration, set the card type and settings manually. This is often a symptom of inadequate emulation for Sound Blaster by a third-party card. If you have problems, check the game developer's or audio adapter's Web site for patches or workarounds.

Choosing the Best Audio Adapter for Your Needs

Although sound features in computers have become commonplace, the demand for sophisticated uses for sound hardware have grown and demanded more and more powerful hardware. If your idea of a perfect multimedia PC includes any of the following, the plain-vanilla multimedia hardware found in many of today's PCs won't be sufficient:

- Realistic 3D and 360° sound for games
- Theater-quality audio for DVD movies
- Voice dictation and voice command
- Creating and recording MIDI, MP3, CD-Audio, and WAV audio files

Table 16.1 summarizes the additional hardware features and software you'll need to achieve the results you want with your high-performance audio adapter. The following sections examine in detail these advanced uses and the features you'll need for each.

Table 16.1 Audio Adapter Intended Uses and Features Comparison

Intended Use	Features You Need	Additional Hardware	Additional Software
Gaming	Game port; 3D sound; audio acceleration	Gaming controller; rear speakers	Games
DVD movies	Dolby 5.1 decoding	Dolby 5.1 speakers compatible with audio adapter	MPEG decoding program
Voice dictation and voice command	Audio adapter on software's compatibility list or equal to SB16 in quality	Voice-recognition microphone	Voice-dictation software
Creating MIDI files	MIDI In adapter	MIDI-compatible musical keyboard	MIDI composing program
Creating MP3 files	Digital audio extraction	CD-R or CD-RW drive	MP3 ripper
Creating WAV files	Microphone	CD-R or CD-RW drive	Sound recording program
Creating CD audio files	External sound source	CD-R or CD-RW drive	WAV or MP3 to CD audio conversion program

The following sections discuss many of these special uses in detail.

Gaming

Thanks to the widespread availability of audio adapters, game playing has taken on a new dimension. Support for 3D and surround digitized sound and realistic MIDI music in current games has added a level of realism that would otherwise be impossible even with today's sophisticated graphics hardware. Mere stereo playback isn't good enough for hardcore gamers who want to be able to hear monsters behind them or feel the impact of a car crash. These users should choose sound cards with support for four or more speakers and some form of directional sound, such as the Creative Labs EAX technology used in Sound Blaster Live! or the Audigy or Sensaura 3D Positional Audio (3DPA) used by ESS, VideoLogic, Cirrus Crystal Logic, Analog Devices, C-Media, and NVIDIA. Many sound cards feature support for these standards, either through direct hardware support or through software emulation and conversion. As with 3D video cards (see Chapter 15, "Video Hardware"), most cards today merely need to work with the 3D audio APIs included in the current revision of Microsoft's DirectX technology.

Any audio adapter built in the last few years will still work with today's games, thanks in large part to the Hardware Emulation Layer (HEL) built into DirectX. HEL emulates the features of newer hardware, such as 3D sound, on older hardware. However, as you can imagine, the task of emulating advanced performance on older hardware can slow down gameplay and doesn't produce sounds as realistic as those available with today's best audio adapters.

Sound Card Minimums for Gameplay

The replacement of the old ISA Sound Blaster Pro standard by PCI sound card standards has helped improve performance a great deal, but for the best gameplay with current and forthcoming titles, you need to consider sound cards with the following features:

- *3D audio support in the chipset.* 3D audio means you'll be able to hear sounds appear to move toward you, away from you, and at various angles corresponding to what's happening onscreen. Microsoft's DirectX, version 8.x, includes support for 3D audio, but you'll have faster 3D audio performance if you use an audio adapter with 3D support built in. DirectX 8.x works along with proprietary 3D audio APIs, such as Creative's EAX and EAX 2.0, Sensaura's 3D Positional Audio, and the A3D technology from now-defunct Aureal.
- *3D sound acceleration.* Sound cards using chipsets with this feature require very little CPU utilization, which speeds up overall gameplay. For best results, use a chipset that can accelerate a large number of 3D streams; otherwise, the CPU will be bogged down with managing 3D audio. This can slow down gameplay, particularly on systems with processors running under 1GHz or that are running at a high-resolution, high-color depth setting (1,024×768/32-bit).
- *Game ports with support for force-feedback game controllers*. If your games don't work properly with USB controllers, or your force-feedback game controllers use the game port only, check the game port features to make sure you'll feel as well as hear and see the action.

Features such as these don't necessarily cost a ton of money; many of the mid-range audio adapters on the market ($50–$100 at retail) support at least the first two features. With new 3D audio chipsets available from a number of vendors, it might be time for you to consider an upgrade if you're heavily into 3D gaming.

Legacy (MS-DOS) Game Support Issues

Support for the classic Sound Blaster Pro standard was once the primary requirement for a good gaming audio adapter, but with the rise of great Windows-based games and the development of DirectX, this is no longer the case for many users.

If you want to play both MS-DOS and Windows games on the same computer, you need to understand the implications of the changes in the newer audio adapters. Emulating the Sound Blaster with a PCI-based sound card is difficult because today's PCI audio adapters and motherboard-based audio solutions don't use separate DMA channels the same way that ISA cards and motherboard resources do. DMA support is vital to achieving a high degree of compatibility with software written for the older Sound Blaster Pro or Sound Blaster 16 cards.

Four methods are used by PCI-based sound cards to emulate Sound Blaster at the DMA hardware level demanded by older DOS and some early Windows games:

- DDMA (Distributed DMA), developed by Compaq
- TDMA (Transparent DMA), developed by ESS Technology
- PC/PCI interface, developed by Intel and Creative Labs
- TSR (memory-resident) utility programs

Distributed DMA and Transparent DMA are similar; both convert calls to the 8237 DMA controller (no longer present on PCI-based motherboards) into calls to a master DMA central resource, which converts the signals into a form compatible with the way PCI-based systems handle DMA transfers. No external connector is required for these features; just enable the Sound Blaster compatibility feature in your audio adapter's setup to activate these features. This is the easiest way for you to achieve Sound Blaster compatibility if you still need it.

The PC/PCI interface, which uses a 6-pin ribbon cable to connect the sound card to a special motherboard header, is supported by several recent Intel and third-party motherboards and some recent

sound cards made by Creative Labs and others. If you want to learn more about PC/PCI (also called the SB-Link connector), see the section "SB-Link Connectors" in Chapter 12 of *Upgrading and Repairing PCs, 12th Edition*, included on the DVD with this book.

All these methods require that the feature be built into both the motherboard and the sound card. Many recent PCI-based sound cards support the first two of these options, easing the issue of finding a match between your motherboard and your sound card's method of emulating the Sound Blaster.

The least desirable method for emulating a Sound Blaster under DOS has made a comeback after fading from view a few years ago: requiring the user to load a Terminate and Stay Resident (TSR) program into RAM before starting the DOS-based game or educational program. For example, the Sound Blaster Audigy series modifies the DOS-mode `Autoexec.bat` and `Config.sys` files to use the memory-resident SBEINIT.COM driver along with the Windows HIMEM.SYS and EMM386.EXE memory managers to enable DOS games to run. A poorly written driver could also cause problems with sound card detection by your game and compatibility problems with some games.

For these reasons, if you have an older sound card that works well with your DOS-based games, you might want to keep it installed if you can spare the hardware resources it uses. Additionally, if you bought an early PCI-based sound card that doesn't work well with DOS games, consider upgrading to a model that uses a high-quality method of emulating the Sound Blaster Pro.

Avoiding Game Port Conflicts

On older systems that use multi-I/O type cards to provide serial and parallel ports and on low-cost systems based on integrated audio chipsets such as the Intel 810, an audio card's game port could be a potential area of conflict because these cards sometimes also include a game port. You must disable one of the game interfaces if you have duplicate game ports. To learn how to disable a duplicate game port, see the section "Resolving Resource Conflicts," later in this chapter.

In many cases, you might not need to use the game port/MIDI port for gaming controllers. Many current game controllers often offer both USB and the traditional game port connectors, allowing you to use the control with either type of connector, although some features might work only when the USB port is used.

The game port is still useful for older games that might not recognize a USB-attached game controller. If you have invested in a high-performance game port, such as the Thrustmaster ACM Game card (`www.thrustmaster.com`) designed for fast PCs, and sophisticated controllers, such as driving wheels, force-feedback joysticks, and so on, you should disable the sound card's game port and use the separate one you installed. If you have a plain-vanilla standard game port, remove it or disable it and use the game adapter port on your audio adapter, especially if you plan to use the MIDI port.

Tip

If your sound card uses a header cable and a second expansion slot for the game port, as is the case with the Sound Blaster Audigy series, but you don't use the game port for anything, you can disconnect the game port from your sound card and free up a PCI slot.

DVD Movies on Your Desktop

You don't need a dedicated DVD player to enjoy the clarity, control, extra features, and excitement of DVD movies. DVD-ROM drives help bring the DVD movie experience to your PC, but having a DVD-ROM and a DVD movie player program is only part of what you need to bring the big screen to your desktop.

To get the most out of your desktop DVD experience, you need the following:

- *DVD playback software that supports Dolby Digital 5.1 output.* One of the best choices is Cyberlink's PowerDVD4.x, available from `www.gocyberlink.com`.
- *An audio adapter that supports Dolby Digital input from the DVD drive and will output to Dolby Digital 5.1-compatible audio hardware.* Some will remix Dolby 5.1 to work on four-speaker setups if you don't have Dolby 5.1 hardware or will accept S/PDIF AC3 (Dolby Surround) input designed for a four-speaker system; some can also pass through Dolby Digital audio to speakers that can perform the Dolby Digital 5.1 decoding.
- *Dolby Digital 5.1-compatible stereo receiver and speakers.* Most high-end sound cards with Dolby Digital 5.1 support connect to analog-input Dolby Digital 5.1 receivers, but some, such as the Creative Labs Sound Blaster Live! Platinum series and the newer Sound Blaster Audigy Platinum and Platinum EX, also support digital-input speaker systems by adding an optional Digital DIN connector to the card. Depending on which types of speakers you are using and how they are attached, you might need to switch your mixer settings in Windows from analog to digital to hear sounds from your applications (movies, games, and so on).

To learn more about speaker terminology and how to ensure your speaker configuration is correct, see the section "Speakers," later in this chapter.

Voice Dictation and Control

Some audio adapters are equipped with software capable of voice recognition that can be used to control some of your computer's operations. You also can get voice recognition for your current adapter in the form of add-on software. Voice recognition, as the name implies, is when your computer is "taught" to recognize spoken word forms and react to them. Voice recognition products generally take two forms: those that are designed to provide a simple voice interface to basic computer functions and those that can accept vocal dictation and insert the spoken text into an application, such as a word processor. The minimum standard for most voice-recognition software is a Sound Blaster 16 or equivalent sound card.

Voice Command Software

The voice interface application is clearly the simpler of the two because the software has to recognize only a limited vocabulary of words. With this type of software, you can sit in front of your computer and say the words "file open" to access the menu in your active Windows application.

For the average user, this type of application is of dubious value. For a time, Compaq was shipping computers to corporate clients with a microphone and an application of this type at little or no additional cost. The phenomenon of dozens of users in an office talking to their computers was interesting, to say the least. The experiment resulted in virtually no increased productivity, a lot of wasted time as users experimented with the software, and noisier offices.

However, for users with physical handicaps that limit their ability to use a keyboard, this type of software can represent a whole new avenue of communication. For this reason alone, continued development of voice-recognition technology is essential.

Note

Voice-recognition applications, by necessity, have to be somewhat limited in their scope. For example, it quickly becomes a standard office joke for someone to stick his head into another person's cubicle and call out "Format C!" as though this command would erase the user's hard drive. Obviously, the software must be incapable of damaging a user's system because of a misinterpreted voice command.

Voice Dictation Software

The other type of voice-recognition software is far more complex. Converting standard speech into text is an extraordinarily difficult task, given the wide variation in human speech patterns. For this reason, nearly all software of this type (and some of the basic voice command applications, as well) must be "trained" to understand a particular user's voice. You do this training by reading prepared text samples supplied with the software to the computer. Because the software knows what you're supposed to be saying beforehand, it can associate certain words with the manner in which you speak them.

Users' results with this type of application vary widely, probably due in no small part to their individual speech patterns. I've heard people rave about being able to dictate pages of text without touching the keyboard, whereas others claim that correcting the many typographical errors is more trouble than typing the text manually.

Note

For more information about voice-recognition, see "Voice Dictation Software" in Chapter 20 of *Upgrading and Repairing PCs, 12th Edition*, included on the DVD-ROM accompanying this book.

Sound Producers

Sound producers are people who intend to create their own sound files. These can range from casual business users recording low-fidelity voice annotations to professional musicians and MIDI maniacs. These users need an adapter that can perform as much of the audio processing as possible itself, so as not to place an additional burden on the system processor. Adapters that use DSPs to perform compression and other tasks are highly recommended in this case. Musicians will certainly want an adapter with as many voices as possible and a wavetable synthesizer. Adapters with expandable memory arrays and the capability to create and modify custom wavetables are also preferable.

Many of the best sound cards for hardcore gamers also are suitable for sound producers by adding the appropriate sound-editing programs, such as Sound Forge, and by equipping the card with the appropriate connectors for SPDIF digital audio and MIDI interfaces. The Sound Blaster Live! Platinum Edition features a drive bay–mounted external interface for these features called the Live Drive. This accessory can also be purchased separately and retrofitted to most other Sound Blaster Live! models.

The latest Sound Blaster Audigy Platinum and Platinum EX also support an updated version of the Live Drive! known as the Audigy Drive. Plus, Hercules' Game Theater XP includes a breakout box. The Creative Labs Extigy provides features similar to those found on the SB Live! Platinum series, but it can be added to any system with a USB port. Most other audio cards designed for sound production features add jacks to the traditional trio of connectors on the rear card bracket.

Playing and Creating Digitized Sound Files

You can use two basic types of files to store audio on your PC. One type is generically called a sound file and uses formats such as WAV, VOC, AU, and AIFF. Sound files contain waveform data, which means they are analog audio recordings that have been digitized for storage on a computer. Just as you can store graphic images at different resolutions, you can have sound files that use various resolutions, trading off sound quality for file size. The default sound resolution levels used in Windows are shown in Table 16.2.

Table 16.2 Windows Default Sound File Resolutions

Format	Resolution	Frequency	Bandwidth	File Size
PCM	Telephone quality	11,025Hz	8-bit mono	11KB/sec
	Radio quality	22,050Hz	8-bit mono	22KB/sec
	CD quality	44,100Hz	16-bit stereo	172KB/sec

If you have a sound card that supports DVD-quality (48,000Hz, 16-bit stereo, 187KB/second), you can also save sounds at that frequency, but you must select it manually if you are using the Windows Sound Recorder to digitize sounds. Note that the Windows Sound Recorder applet uses the default Pulse Code Modulation (PCM) method for storing sounds. PCM produces the highest quality of sound, but because it doesn't use any type of data compression, file sizes can be enormous.

As you can see, the difference in file sizes between the highest and lowest audio resolution levels is substantial. CD-quality sound files can occupy enormous amounts of disk space. At this rate, just 60 seconds of audio would require more than 10MB of storage. For applications that don't require or benefit from such high resolution, such as voice annotation, telephone-quality audio is sufficient and generates much smaller files. To achieve a balance between high quality and smaller file sizes, you can convert conventional WAV files into compressed formats, such as MP3 or WMA audio files.

The other type of file is a MIDI file, which consists of a musical score that is played back by synthesized or sampled musical instruments incorporated into the sound card's MIDI support.

Note

To learn more about the differences between MP3, WMA, and MIDI files, see "Audio Compression and MIDI Files" in the Technical Reference located on the DVD-ROM packaged with this book.

On a multimedia PC, it is often possible for two or more sound sources to require the services of the audio adapter at the same time. Any time you have multiple sound sources you want to play through a single set of speakers, a mixer is necessary.

Most audio adapters include a mixer that enables all the different audio sources, MIDI, WAV, line in, and CD to use the single line-out jack. Starting with Windows 95 through the latest Windows versions (XP Pro/XP Home), Windows uses a single mixer for both recording and playback features, instead of using separate mixers as with Windows 3.x. Normally, the adapter ships with software that displays visual sliders like you would see on an actual audio mixer in a recording studio. With these controls, you can set the relative volume of each of the sound sources.

Tip

Whenever you change from analog to digital speakers or add speakers to a two-speaker configuration, you must adjust the mixer controls to match your current speaker configuration. If you don't, you will be unable to hear anything through your speakers.

Audio Adapter Concepts and Terms

To fully understand audio adapters and their functions, you need to understand various concepts and terms. Terms such as 16-bit, CD quality, and MIDI port are just a few. Concepts such as sampling and digital-to-audio conversion (DAC) are often sprinkled throughout stories about new sound products. You've already learned about some of these terms and concepts; the following sections describe many others.

The Nature of Sound

To understand an audio adapter, you must understand the nature of sound. Every sound is produced by vibrations that compress air or other substances. These sound waves travel in all directions, expanding in balloon-like fashion from the source of the sound. When these waves reach your ear, they cause vibrations that you perceive as sound.

Two of the basic properties of any sound are its pitch and intensity.

Pitch is the rate at which vibrations are produced. It is measured in the number of hertz (Hz), or cycles per second. One cycle is a complete vibration back and forth. The number of Hz is the frequency of the tone; the higher the frequency, the higher the pitch.

Humans can't hear all possible frequencies. Very few people can hear sounds with frequencies less than 16Hz or greater than about 20KHz (kilohertz; 1KHz equals 1,000Hz). In fact, the lowest note on a piano has a frequency of 27Hz, and the highest note has a frequency a little higher than 4KHz. Frequency-modulation (FM) radio stations can broadcast notes with frequencies as high as 15KHz.

The amazing compression ratios possible with MP3 files, compared to regular CD-quality WAV files, is due in part to the discarding of sound frequencies that are higher or lower than normal hearing range during the ripping process.

The intensity of a sound is called its *amplitude*. This intensity determines the sound's volume and depends on the strength of the vibrations producing the sound. A piano string, for example, vibrates gently when the key is struck softly. The string swings back and forth in a narrow arc, and the tone it sends out is soft. If the key is struck more forcefully, however, the string swings back and forth in a wider arc, producing a greater amplitude and a greater volume. The loudness of sounds is measured in decibels (db). The rustle of leaves is rated at 20db, average street noise at 70db, and nearby thunder at 120db.

Evaluating the Quality of Your Audio Adapter

The quality of an audio adapter is often measured by three criteria: frequency response (or range), total harmonic distortion, and signal-to-noise ratio.

The *frequency response* of an audio adapter is the range in which an audio system can record or play at a constant and audible amplitude level. Many cards support 30Hz–20KHz. The wider the spread, the better the adapter.

The *total harmonic distortion* measures an audio adapter's linearity and the straightness of a frequency response curve. In layman's terms, the harmonic distortion is a measure of accurate sound reproduction. Any nonlinear elements cause distortion in the form of harmonics. The smaller the percentage of distortion, the better. This harmonic distortion factor might make the difference between cards that use the same audio chipset. Cards with cheaper components might have greater distortion, making them produce poorer-quality sound.

The *signal-to-noise ratio (S/N or SNR)* measures the strength of the sound signal relative to background noise (hiss). The higher the number (measured in decibels), the better the sound quality. For example, the top-of-the-line Sound Blaster Audigy sound cards feature an SNR of 100db, whereas the older Sound Blaster AWE64 series has an SNR of 90db.

These factors affect all types of audio adapter use, from WAV file playback to speech recognition. Keep in mind that low-quality microphones and speakers can degrade the performance of a high-quality sound card.

Sampling

With an audio adapter, a PC can record waveform audio. Waveform audio (also known as sampled or digitized sound) uses the PC as a recording device (like a tape recorder). Small computer chips built into the adapter, called analog-to-digital converters (ADCs), convert analog sound waves into digital bits that the computer can understand. Likewise, digital-to-analog converters (DACs) convert the recorded sounds to an audible analog format.

Sampling is the process of turning the original analog sound waves into digital (binary) signals that the computer can save and later replay (see Figure 16.7). The system samples the sound by taking snapshots of its frequency and amplitude at regular intervals. For example, at time X the sound might be measured with an amplitude of Y. The higher (or more frequent) the sample rate, the more accurately the digital sound replicates its real-life source and the larger the amount of disk space needed to store it.

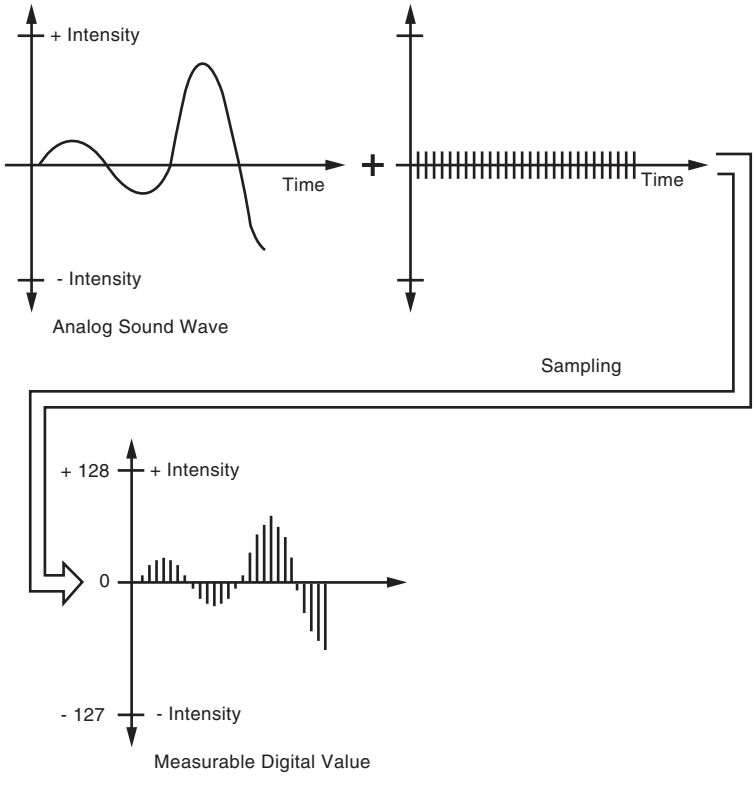

Figure 16.7 Sampling turns a changing sound wave into measurable digital values.

Originally, sound cards used 8-bit digital sampling that provided for only 256 values (2^8), which could be used to convert a sound. More recently, sound cards have increased the quality of digitized sound by using 16-bit (2^{16}) sampling to produce 65,536 distinct values. Today's highest-quality sound cards feature 24-bit sampling (2^{24}), which translates into more than 16.8 million possible digital values that can be matched to a given sound.

Note

For more information on the differences between 8-bit and 16-bit audio sampling, see, "8-Bit Versus 16-Bit," in Chapter 16 of *Upgrading and Repairing PCs, 13th Edition*, included on the DVD-ROM accompanying with this book.

You can experiment with the effects of various sampling rates (and compression technologies) by recording sound with the Windows Sound Recorder or a third-party application set to CD-quality sound. Save the sound and play it back at that highest quality setting. Then convert the file to a lower-quality setting, and save the sound file again with a different name. Play back the various versions, and determine the lowest quality (and smallest file size) you can use without serious degradation to sound quality.

Who's Who in Audio

Because audio adapters have become common features in systems, many vendors have produced audio adapters, audio chips, and integrated motherboard chipsets with audio features. This section examines some of these companies and their products.

As you've learned in other chapters, I believe it is very important to get all the technical information you can about your computer and its components. By knowing who makes the audio chip your computer depends on, you can find out what the hardware can do and be better able to find upgrades to the software drivers you need to get the most out of your audio hardware.

Chipset Makers Who Make Their Own Audio Adapters

Just as graphics card vendors are divided into two camps, chipset makers are divided into these two categories:

- Card makers who produce their own chipsets
- Card makers who use chipsets from other vendors

Audio adapter vendors fall into the same categories. One of the pioneers of the audio adapter business, Creative Labs, has also been among the leaders in developing audio chips. Creative Labs develops audio chips primarily for its own Sound Blaster–branded products, but it has sold some of its older Sound Blaster 16 products into OEM markets.

Creative's major audio chips have included the following:

- *Vibra-16.* This was used in the later Sound Blaster 16 cards; it doesn't support wavetable or 3D effects.
- *Ensoniq ES1370 series (ES1370/71/73).* These were used in the Sound Blaster PCI64 and PCI 128 series as well as the Ensoniq Audio PCI and Vibra PCI series. They support soft wavetable features, four speakers on some models and Microsoft Direct 3D but don't support 3D acceleration or EAX positional audio.
- *EMU-8000.* This audio chip was used by the AWE32/64 series and features 32-voice wavetable synthesis but no 3D acceleration. The AWE64 used software to generate 32 additional voices for a total of 64 voices.
- *EMU10K1.* This audio chip was at the heart of the Live! and Live 5.1 series sound cards as well as the PCI 512; it features 3D acceleration, EAX positional audio for one audio stream, a reprogrammable DSP, and soft wavetable support.
- *EMU10K2 (also known as Audigy).* This is the audio chip at the heart of Creative Labs' current Sound Blaster Audigy series sound cards; it features 3D acceleration, EAX HD positional audio

for up to four audio streams, a reprogrammable DSP, and soft wavetable support. This chip supports professional-level 24-bit sampling at 96KHz and real-time sampling at Dolby Digital–quality 24-bit samples at 48KHz.

Another major player is Philips, which bought chipset maker VLSI and integrated it into its Philips Semiconductor operation in mid-1999. Philips introduced its line of audio adapters in the fall of 2000, using the ThunderBird chipsets it jointly developed with Qsound Labs, Inc. These include

- *ThunderBird Q3D*. Features 3D audio acceleration of up to 64 3D streams in hardware, positional 3D audio supporting EAX and Qsound standards, quadraphonic speaker support with virtual surround sound, wavetable, and DOS Sound Blaster emulation; it is used by the original Philips Rhythmic Edge (PSC702) and Seismic Edge (PSC704) audio adapters.
- *ThunderBird Avenger*. Features 3D audio acceleration of up to 96 3D streams in hardware, positional 3D audio supporting EAX and Qsound standards, support for Dolby Digital 5.1, wavetable, and DOS Sound Blaster emulation; it is used by the Philips Seismic Edge 5.1 (PSC705), Rhythmic Edge Surround (PSC703), and Acoustic Edge (PSC706) audio adapters.

These chipsets, which have received high praise for performance, also can be used by other brands of audio adapters in the future because Philips offers these chipsets as OEM products as well as in its own brand of audio adapters.

Various other companies have produced their own sound chips in the past but no longer do so. The two primary makers that fit in this category are

- *Aureal*. Its A3D technology was regarded by many as superior to Creative Labs' original EAX 3D positional audio, but the company was absorbed by Creative Labs in mid-2000. Because Creative's new EAX HD is superior to A3D, there will be no further development of this technology.
- *Yamaha*. Its OPL2 and OPL3 chips were among the best FM-synthesis chips used on older sound cards, and its MIDI performance in later models was outstanding. However, its emphasis is now on MIDI daughtercards and professional sound-recording cards such as the SW1000XG. Some of its retail and OEM products might still be available, though. Yamaha maintains drivers for its branded and some OEM cards at `http://www.yamaha.com/lsi/support/soundcard.htm`.

Should you panic if your favorite audio adapter is an "orphan"? Not necessarily. If the audio adapter vendor provides good technical support and up-to-date drivers, you're okay for now. But, the next time an operating system update or new audio API shows up, you probably won't be able to take advantage of it unless you replace your audio adapter.

Major Sound Chip Makers

Most companies other than Creative Labs and Philips depend on third parties to make their audio chips. Some of the major vendors include

- *Cirrus Logic/Crystal Semiconductors*. The top-of-the-line Sound Fusion CS4630 also features 3D acceleration, support for both EAX and Sensaura positional audio, unlimited-voice wavetable synthesis, and S/PDIF support for AC3 and Dolby 5.1 input and output at rates up to 48KHz. The CS4630 is used in the popular and highly rated Hercules Game Theater XP, Voyetra Turtle Beach Santa Cruz, and similar Video Logic Sonic Fury audio adapters.

  Other Sound Fusion series chips include the CS4614 and CS4624, both of which feature support for 3D Direct Sound positional audio, DOS Sound Blaster emulation, and wavetable synthesis.

- *ESS Technology.* The Canyon3D-2 is ESS Technology's flagship audio chip, featuring four-channel analog output, support for Dolby and THX digital sound, SPDIF input and output, and Sensaura 3D positional audio, and it is optimized for use with DirectX 8.0. It is used by the I/O Magic Hurricane Extreme.

  The Maestro-2 series features wavetable, positional 3D from Sensaura, and 3D audio acceleration; the Maestro 2E and 2EM also support S/PDIF output for DVD movie support. The Maestro series chips are optimized for notebook computers, and Maestro chips are used in recent models of Dell, Toshiba, Gateway, Compaq, and HP portables.

  The Allegro series (ESS-1989 for desktops and ESS-1988 for notebook computers) features DirectSound, Direct3D, S/PDIF output, and Sensaura 3D positional sound. The ESS-1989 is used by the Philips Harmonic Edge (PSC602) sound card as well as models sold by Pine Technologies and others.

  ESS's earlier AudioDrive series was popular with many notebook computers and second-tier sound card makers in the mid-1990s.

- *C-Media Electronics.* The CMI 8738 features 4.1 and 5.1 speaker support for quadraphonic and Dolby Digital output, Direct Sound 3D and A3D positional audio, and wavetable and is available for desktop or notebook computers. It is used by sound cards such as Guillemot's MUSE and Leadtek's WinFast 4x Sound and motherboards made by Asus, Soyo, and others.

- *ForteMedia, Inc.* The FM-801 is the first audio chip to feature Dolby Digital 5.1 output to analog speakers for both DVD movies and games. The FM-801 also features Qsound's Q3D 2.0 3D API and optional support for SPDIF input/output. The FM-801 is used by many smaller sound card makers. For a review of the sound chip and a feature comparison of sound cards using this chip, see `http://www.3dsoundsurge.com/reviews/FM801/FM801.html`.

- *Realtek.* Although it's better known for low-cost Ethernet network card chipsets, Realtek also offers audio chipsets, including the ALC650, which was introduced in March 2002. The ALC650 is the first motherboard integrated chipset to support AC '97 audio along with six-channel output, Dolby Digital 5.1, stereo, and surround sound. It is featured on high-performance motherboards such as the MSI KT3 Ultra ARU.

Discontinued and Orphan Sound Chips and Sound Card Producers

The following sound chips are no longer being sold, and ongoing support is limited or no longer available. If you use an audio adapter based on one of these products, you might need to upgrade if you can't get drivers for new and forthcoming operating systems.

Discontinued products include

- *Oak Technology OTI-601 series.* Oak left the audio chipset business in early 1998.
- *Trident 4DWave-NX series.* This 3D audio chipset is still available on cards from smaller audio adapter vendors, such as Aztech, Jaton, and Hoontech.

Diamond Multimedia, which used sound chips from several vendors, no longer produces sound cards since its parent company, S3, relaunched itself in the fall of 2000 as an Internet appliance and MP3 audio-focused company called SONICblue. SONICblue still offers limited support for Diamond-brand audio cards, but ongoing driver development is no longer taking place.

Motherboard Chipsets with Integrated Audio

The Intel 810 chipset was the first mainstream chipset for a major CPU to integrate audio; it works with Celeron CPUs. Its inspiration might have been the Cyrix/National Semiconductor Media GX

series, which used a trio of chips to substitute for the CPU, VGA video, onboard audio, memory, and I/O tasks.

Thanks to improvements in chipset design and faster CPU performance, today's best integrated chipsets can provide solid mid-range performance. Some of the most recent examples include

- *Intel 815 series for the Celeron and Pentium III.* Supports AC97 and 6-channel output
- *Intel 850 for the Pentium 4.* Supports AC97 and 6-channel output
- *NVIDIA nForce.* Requires use of the nForce MCP-D (South Bridge equivalent) chip with any nForce North Bridge-equivalent chip (SPP with no onboard video), IGP-64 (integrated video with single memory bank), or IGP-128 (integrated video with TwinBank memory architecture). Supports DirectX 8.x, up to 256 audio streams or 64 3D and 192 simultaneous audio streams, and Dolby Digital 5.1 output
- *ATI Radeon IGP series with the ATI IXP 200/250.* Supports AC-Link and S/DPIF audio as well as 3COM 10/100 Ethernet and USB 2.0 ports for desktop or mobile applications
- *SiS 645 and 645DX for the Pentium 4.* Supports AC97 audio and Dolby 5.1 digital output
- *SiS 650 for the Athlon XP.* Supports AC97 audio and Dolby 5.1 digital output

Some of these chipsets require the use of a CMR riser card (a small card that plugs into a dedicated expansion slot on some recent motherboards) to make audio available. Other motherboards that have Audio Modem Riser (AMR) support are available from many vendors; this is intended for a low-cost sound card or modem that will use the CPU and operating system for its intelligence. However, *no* official specification exists for the use of this tiny two-part slot found on many recent motherboards, and thus this option is almost useless unless your motherboard vendor supplies the necessary AMR daughtercard.

Even though multichannel audio performance for DVD and music playback is quite good with the latest integrated chipsets, 3D audio performance for gaming on any system with integrated audio chipsets such as the ones listed previously is likely to be lacking. Because DirectX 8.x supports 3D audio better than previous versions, you should use it for the best results with your audio card (be sure to obtain drivers compatible with your product).

3D Audio

One of the biggest issues for serious game players when audio adapters are considered is how well they perform 3D audio tasks. This has been complicated by several factors, including

- Differing standards for positional audio
- Hardware versus software processing of 3D audio
- DirectX support issues

Positional Audio

The underlying issue common to all 3D sound cards is that of positional audio, which refers to adjusting features such as reverberation; balance; and apparent sound "location" to produce the illusion of sound coming from in front of, beside, or even behind the user. One very important element in positional audio is HRTF (Head Related Transfer Function), which refers to how the shape of the ear and the angle of the listener's head changes the perception of sound. Because HRTF factors mean that a "realistic" sound at one listener's head angle might sound artificial when the listener turns to one side or the other, the addition of multiple speakers that "surround" the user, as well as sophisticated sound algorithms that add controlled reverberation to the mix, are making computer-based sound more and more realistic.

The technology might be promising, but one of the most frustrating problems for PC game players in particular has been the continued rivalry between various APIs designed to perform essentially the same task, such as the battle between the now-defunct 3dfx Glide standard and OpenGL for graphics, or the battle over which 3D audio standard to support. The original version of Microsoft's Direct3D for DirectX didn't support third-party 3D software, but recent and current versions do, enabling 3D audio adapters to improve the normal positional audio available with Direct3D.

During 1999 and the first part of 2000, the major rivals for the most popular gaming 3D standard were Aureal's A3D and Creative Labs' EAX (Environmental Audio Extensions) technology. A3D, especially in version 2.0, was frequently regarded as superior to its Creative Labs rival. However, most developer support went to EAX. When Aureal closed in mid-2000 and was later absorbed by Creative, this spelled the end for A3D as a viable game API.

Virtually all new sound cards on the market support Creative's EAX, while Creative's own Audigy series has gone onto the next level with EAX HD, which supports up to four streams of accelerated 3D audio for amazing environmental effects. However, many other audio adapter vendors are enhancing the effects of EAX by adopting Sensaura's Virtual Ear engine. Virtual Ear enables the user to adjust the apparent position of sound by adjusting the size and shape of the "ear" used to listen to sound. Virtual Ear is currently available on audio adapters from Aopen, Labway, Yamaha, Voyetra Turtle Beach, Guillemot/Hercules, and others. Virtual Ear can be purchased as an upgrade for existing audio adapters that use the ADI SoundMax 2 and Yamaha YMF 724 and 744 chips.

3D Audio Processing

A second important issue for game players is how the sound cards produce 3D audio. As with 3D video, there are two major methods:

- Host-based processing (which uses the CPU to process 3D, which can slow down overall system operation)
- Processing on the audio adapter (referred to as 3D acceleration)

Some 3D audio cards perform some or all of the processing necessary for 3D using the host's CPU, whereas others use a powerful DSP that performs the processing on the audio adapter itself. Cards that use host-based processing for 3D can cause major drops in frame rate (frames per second of animation displayed onscreen by a 3D game) when 3D sound is enabled if you use processors under 1GHz, whereas cards with their own 3D audio processors onboard have little change in frame rate whether 3D sound is enabled or disabled. Many of the latest chips from major audio adapter and chipset vendors support 3D acceleration, but the number of 3D audio streams supported varies greatly by chip—and it can sometimes be limited by problems with software drivers.

A good rule of thumb for realistic gaming is to have an overall average frame rate of at least 30fps (frames per second). With CPUs running at 1GHz or above, this is easy to achieve with any recent 3D card. However, gamers using older CPUs, such as those running slower than 1GHz, will find that cards using the host CPU for some of the 3D processing will have frame rates that fall below the desired average of 30fps, making for clumsy gameplay. To see the effect of enabling 3D sound on the speed of popular games, you can use the built-in frame-rate tracking feature found in many games or check online game-oriented hardware review sources, such as `www.anandtech.com`. Frame rates are closely related to CPU utilization; the more CPU attention your 3D audio card requires, the slower the frame rate will be.

As with 3D video, the main users of 3D sound are game developers, but business uses for ultra-realistic sound will no doubt follow.

DirectX Support Issues

The latest version of DirectX, DirectX 8.x, is designed to give all sound cards with 3D support a major boost in performance. Previous versions of DirectX supported 3D with DirectSound3D, but the performance of DirectSound3D was limited. Game programmers needed to test the audio adapter to see whether it supported DirectSound3D acceleration and then would either enable or disable 3D sounds based on the host hardware. Starting with DirectX 5.0, DirectSound3D works with third-party 3D acceleration features.

Installing the Sound Card

Before you can install a sound card, you must open your computer. In almost all cases today, you will install a PCI audio adapter that supports Plug and Play configuration. Compared to the previous generation of ISA audio adapters, PCI audio adapters use fewer hardware resources, feature a lower CPU utilization rate, and provide better support for advanced 3D gaming APIs.

If you need to install an ISA audio adapter, see "Installing the Sound Card (Detailed Procedure)" in Chapter 20 of *Upgrading and Repairing PCs, 11th Edition*, supplied in electronic form on the DVD packaged with this book.

If you have several empty bus slots from which to choose, install the audio adapter in the slot that is as far away as possible from the other cards in the computer. This reduces any possible electromagnetic interference; that is, it reduces stray radio signals from one card that might affect the sound card. The analog components on audio adapters are highly susceptible to interference, and even though they are shielded, they should be protected as well as is possible. Next, you must remove the screw that holds the metal cover over the empty expansion slot you've chosen. Remove your audio adapter from its protective packaging. When you open the bag, carefully grab the card by its metal bracket and edges. Do not touch any of the components on the card because any static electricity you might transmit can damage the card. Also, do not touch the gold-edge connectors. You might want to invest in a grounding wrist strap, which continually drains you of static build-up as you work on your computer.

Before you make your final decision about which slot to use for your audio adapter, take a careful look at the external cables you must attach to the card. Front and rear speakers, microphone, game controller, line in, S/PDIF, and other cables that attach to your system can interfere with (or be interfered by) existing cables already attached to your system. It's usually best to choose a slot that allows you to route the audio cables away from other cables. If you're installing a Sound Blaster Live! or Audigy series card that uses an internal 5 1/4" breakout box (Live! Drive or Audigy Drive), be sure the ribbon cable from the drive bay used for the breakout box can comfortably reach the connector on the sound card. You might have to move a CD-ROM, CD-RW, or DVD drive to a different drive bay to free up a drive bay needed by the breakout box.

If your system has an internal CD-ROM drive with an analog audio cable, connect the audio cable to the adapter's CD Audio In connector. This connector is a four-pin connector and is keyed so that you can't insert it improperly. Note that no true standard exists for this audio cable, so be sure you get the correct one that matches your drive and adapter. If you need to purchase one, you can find cables with multiple connectors designed for various brands of CD-ROM drives. This will allow you to play music CDs through the sound card's speakers and to use analog ripping if you want to create MP3 files from your CDs.

Many recent CD-ROM and DVD drives also have a digital audio connector that supports a two-wire connector. Attach one end of the digital audio cable to the rear of the drive and the other end to the CD SPDIF or CD Digital Audio connector on the sound card. This enables you to perform digital ripping if you want to create MP3 files from your CDs.

Next, insert the adapter's edge connector in the bus slot, but first touch a metal object, such as the inside of the computer's cover, to drain yourself of static electricity. When the card is firmly in place, attach the screw to hold the expansion card and then reassemble your computer.

Connecting PC Speakers and Completing the Installation

After the adapter card is installed, you can connect small speakers to the external speaker jack(s). Typically, sound cards provide 4 watts of power per channel to drive bookshelf speakers. If you are using speakers rated for less than 4 watts, do not turn up the volume on your sound card to the maximum; your speakers might burn out from the overload. You'll get better results if you plug your sound card into powered speakers—that is, speakers with built-in amplifiers. If your sound card supports a four-speaker system, check the documentation to see which jack is used for the front speakers and which for the rear speakers. To use the rear speakers for 3D audio, adjust the properties with the mixer control software supplied with your sound card.

Tip

If you have powered speakers but don't have batteries in them or have them connected to an AC adapter, don't turn on the speakers! Turning on the speakers without power will prevent you from hearing anything at all. Leave the speakers turned off and use the volume control built into your sound card's mixer software instead. Powered speakers sound better, but most small models can run without power in an emergency.

Some computer power supplies feature small jacks to provide power for computer speakers.

When the sound card installation is finished, you should have a speaker icon in the Windows System Tray. If the speaker icon (indicating the Volume Control) isn't visible, you can install it through the Control Panel's Add/Remove Programs icon. With Windows 9x/Me, select the Windows Setup tab and open the Multimedia section. Then, check the box labeled Volume Control. With Windows XP, open the Sounds and Audio Devices icon in Control Panel, click the Volume tab, and click the Place Volume icon in the taskbar box. Insert the Windows CD-ROM if requested to complete the installation.

If you use digital sound sources or output such as Dolby 5.1, CD digital, or S/PDIF, open the properties sheet for your mixer device and enable display of these volume controls.

Use the Volume Control to ensure your speakers are receiving a sound signal. The mixer sometimes defaults to Mute. You can usually adjust volume separately for wave (WAV) files, MIDI, microphone, and other components.

Using Your Stereo Instead of Speakers

Another alternative is to patch your sound card into your stereo system for greatly amplified sound and for support of advanced Dolby Digital sound for DVD playback. Check the plugs and jacks at both ends of the connection. Most stereos use pin plugs, also called RCA or phono plugs, for input. Although pin plugs are standard on some sound cards, most use miniature 1/8" phono plugs, which require an adapter when connecting to your stereo system. For example, from Radio Shack you can purchase an audio cable that provides a stereo 1/8" miniplug on one end and phono plugs on the other (Cat. No. 42-2481A). If you want to attach your sound card to Dolby 5.1 speakers, be sure you use cabling designed for the S/PDIF connectors on your sound card. Some might use RCA-type plugs, whereas others use an optical cable with a square end.

Make sure that you get stereo—not mono—plugs, unless your sound card supports only mono. To ensure that you have enough cable to reach from the back of your PC to your stereo system, get a 6-ft. long cable.

Hooking up your stereo to an audio adapter is a matter of sliding the plugs into the proper jacks. If your audio adapter gives you a choice of outputs—speaker/headphone and stereo line-out—choose the stereo line-out jack for the connection. This will give you the best sound quality because the signals from the stereo line-out jack are not amplified. The amplification is best left to your stereo system. In some cases, you'll attach a special DIN plug to your audio adapter that has multiple connections to your stereo system.

Connect this cable output from your audio adapter to the auxiliary input of your stereo receiver, preamp, or integrated amplifier. If your stereo doesn't have an auxiliary input, other input options include—in order of preference—tuner, CD, or Tape 2. (Do not use phono inputs, however, because the level of the signals will be uneven.) You can connect the cable's single stereo miniplug to the sound card's stereo line-out jack, for example, and then connect the two RCA phono plugs to the stereo's Tape/VCR 2 Playback jacks.

The first time you use your audio adapter with a stereo system, turn down the volume on your receiver to prevent blown speakers. Barely turn up the volume control and then select the proper input (such as Tape/VCR 2) on your stereo receiver. Finally, start your PC. Never increase the volume to more than three-fourths of the way up. Any higher and the sound might become distorted.

Note

If your stereo speakers are not magnetically shielded, you might hear a lot of crackling if they are placed close to your computer. Try moving them away from the computer, or use magnetically shielded speakers.

Tricks for Using the Tape Monitor Circuit of Your Stereo

Your receiver might be equipped with something called a tape monitor. This outputs the sound coming from the tuner, tape, or CD to the tape-out port on the back; it then expects the sound to come back in on the tape-in port. These ports, in conjunction with the line-in and line-out ports on your audio adapter, enable you to play computer sound and the radio through the same set of speakers.

Here's how you do it:

1. Turn off the tape monitor circuit on your receiver.
2. Turn down all the controls on the sound card's mixer application.
3. Connect the receiver's tape-out ports to the audio adapter's line-in port.
4. Connect the audio adapter's line-out port to the receiver's tape-in ports.
5. Turn on the receiver, select some music, and set the volume to a medium level.
6. Turn on the tape monitor circuit.
7. Slowly adjust the line-in and main-out sliders in the audio adapter's mixer application until the sound level is about the same as before.
8. Disengage and re-engage the tape monitor circuit while adjusting the output of the audio adapter so that the sound level is the same regardless of whether the tape monitor circuit is engaged.
9. Start playing a WAV file.
10. Slowly adjust up the volume slider for the WAV file in the audio adapter's mixer application until it plays at a level (slightly above or below the receiver) that is comfortable.

Now you can get sounds from your computer and the radio through the receiver's speakers.

Different connectors might be needed if you have digital surround speakers and newer PCI-based sound cards. Check your speakers and sound card before you start this project.

Troubleshooting Sound Card Problems

To operate, an audio adapter needs hardware resources, such as IRQ numbers, a base I/O address, and DMA channels that don't conflict with other devices. Most adapters come preconfigured to use the standard Sound Blaster resources that have come to be associated with audio adapters. However, problems occasionally arise even with Plug and Play adapters. Troubleshooting might mean that you have to change the settings used by your system BIOS for PnP devices, move the sound card to another slot, or even reconfigure the other devices in your computer. No one said life was fair.

Hardware (Resource) Conflicts

The most common problem for audio adapters (particularly if you still use ISA cards) is that they conflict with other devices installed in your PC. You might notice that your audio adapter simply doesn't work (no sound effects or music), repeats the same sounds over and over, or causes your PC to freeze. This situation is called a device, or hardware, conflict. What are they fighting over? Mainly the same bus signal lines or channels (called resources) used for talking to your PC. The sources of conflict in audio adapter installations are generally threefold:

- *Interrupt Requests (IRQs).* Hardware devices use IRQs to "interrupt" your PC's CPU and get its attention. PCI cards can share IRQs, but ISA cards and onboard legacy ports such as serial, parallel, and PS/2 mouse ports can't.
- *Direct Memory Access (DMA) channels.* DMA channels move information directly to your PC's memory, bypassing the system processor. DMA channels enable sound to play while your PC is doing other work. ISA sound cards and PCI sound cards emulating the Sound Blaster standard require DMA settings; PCI sound cards running in native mode don't use DMA channels.
- *Input/output (I/O) port addresses.* Your PC uses I/O port addresses to channel information between the hardware devices on your audio adapter and PC. The addresses usually mentioned in a sound card manual are the starting or base addresses. An audio adapter has several devices on it, and each one uses a range of addresses starting with a particular base address.

Most audio adapters include installation software that analyzes your PC and attempts to notify you if any of the standard settings are in use by other devices. The Windows Device Manager (accessed from the System Control Panel) can also help you to resolve conflicts. Although these detection routines can be fairly reliable, unless a device is operating during the analysis, it might not always be detectable.

Some of the newer PCI-based sound cards and Intel chipset motherboards might not properly support ISA-type I/O addresses used by Sound Blaster–compatible software to communicate with the card. If you have problems getting older games to work with your system, see the tips listed earlier for emulation methods, check with your sound card and system board/computer supplier for help, and check with the game developer for possible patches and workarounds.

Table 16.3 shows the default resources used by the components on a typical Sound Blaster 16 card, which uses a 16-bit ISA slot. Other sound cards used to emulate a Sound Blaster typically use these same settings.

Table 16.3 Default Sound Blaster Resource Assignments

Device	Interrupt	I/O Ports	16-Bit DMA	8-Bit DMA
Audio	IRQ 5	220h–233h	DMA 5	DMA 1
MIDI Port	—	330h–331h	—	—
FM Synthesizer	—	388h–38Bh	—	—
Game Port	—	200h–207h	—	—

All these resources are used by a single sound card in your system. No wonder so many people have conflicts and problems with audio adapter installations! In reality, working out these conflicts is not all that hard, as you will see. You can change most of the resources that audio adapters use to alternative settings, if conflicts with other devices occur; even better, you can change the settings of the other device to eliminate the conflicts. Note that some devices on the audio adapter, such as the MIDI port, FM synthesizer, and game port, do not use resources such as IRQs or DMA channels.

Compare the resource settings used by a traditional ISA sound card (refer to Table 16.3) to those used by a typical PCI-based sound card (see Table 16.4).

Table 16.4 Typical Sound Blaster Audigy Resource Assignments

Device	Interrupt	I/O Ports	16-Bit DMA	8-Bit DMA
Audio	IRQ 3	4000–401F	—	—
MIDI Port	(included in above configuration)			
FM Synthesizer	(included in above configuration)			
Game Port	—	1400–1407	—	—

If you don't need MS-DOS game support, the PCI card uses far fewer resources than the ISA card. However, if you are using MS-DOS games, you will need to set up a number of "virtual" IRQ, I/O port, and DMA port settings for use with those games only.

When using a typical PCI-based sound card's Sound Blaster Legacy settings, you must verify that MS-DOS software using the Sound Blaster is set for the appropriate configuration (see Figure 16.8).

If you are still using MS-DOS games (or even some Windows programs designed for Windows 95 or earlier), I recommend that you install your audio adapter (or configure a notebook computer's built-in sound adapter circuits) to use the default settings whenever possible. This is mainly because of poorly written software that can't work properly with alternative settings, even if they do not cause conflicts. In other words, if you are having a conflict with another type of adapter, modify the settings of the other device, rather than those of the audio adapter. Take this from experience; otherwise, you will have to explain to your five-year-old why the new Dinosaur program you just installed does not make any sounds! This problem is primarily associated with DOS-based game programs, but some older Windows-based programs have also been incapable of working with alternative hardware settings.

Note

Some of the recent chipsets for "legacy-free" systems, such as the Intel 810 and 820 chipsets, don't decode addresses below 1000h to the PCI bus. All the Sound Blaster I/O port addresses are well below 1000h, and thus sound card manufacturers will need to adjust driver software or use TSR programs to reroute calls to these I/O port addresses by software to the correct I/O port addresses. This design choice is not a problem for typical Windows software that uses sound, but it can cause legacy (DOS-based) applications to fail.

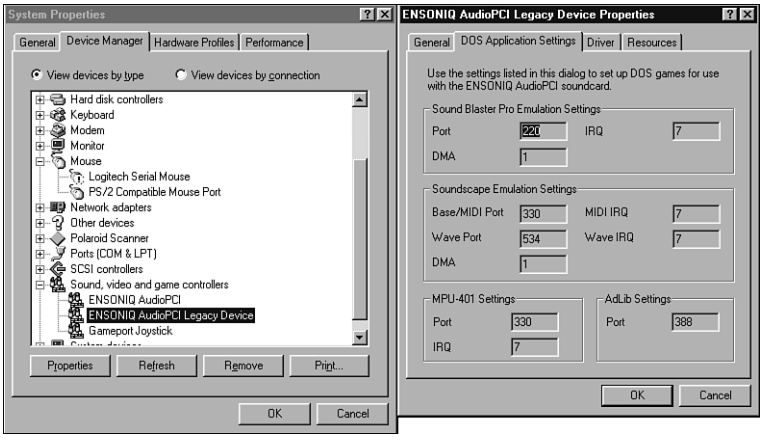

Figure 16.8 One advantage of PCI cards is visible here, even in emulation mode: All emulations can use the same IRQ, rather than up to three different IRQs, as is the case with most third-party ISA cards that emulate the Sound Blaster.

Resolving Resource Conflicts

Resource conflicts are quite rare with current PCI-based audio adapters, thanks to their support of Windows Plug and Play technology and the PCI IRQ sharing/steering feature supported by Windows 95 OSR 2.x and above and recent chipsets.

However, if you are still using the original version of Windows 95 or an ISA-based audio adapter (including some motherboard-based chipsets on older systems), you can have significant problems because of IRQ and DMA conflicts with other devices.

◀◀ See *Upgrading and Repairing PCs, 12th Edition* on the DVD-ROM for details.

Other Sound Card Problems

Like the common cold, audio adapter problems have common symptoms. Use the following sections to diagnose your problem.

No Sound

If you don't hear anything from your audio adapter, consider these solutions:

- Make sure the audio adapter is set to use all default resources and that all other devices using these resources have been either reconfigured or removed. Use the Device Manager to determine this information.
- Are the speakers connected? Check that the speakers are plugged into the sound card's stereo line-out or speaker jack (not the line-in or microphone jack).
- Are the speakers receiving power? Check that the power "brick" or power cord is plugged in securely.
- Are the speakers stereo? Check that the plug inserted into the jack is a stereo plug, not mono.
- Are the mixer settings correct? Many audio adapters include a sound mixer application. The mixer controls the volume settings for various sound devices, such as the microphone or the CD player. There might be separate controls for both recording and playback. Increase the master volume or speaker volume when you are in the play mode.

If the Mute option is selected in your sound mixer software, you won't hear anything. Depending on the speaker type and sound source type, you might need to switch from analog to digital sound for some types of sound output. Make sure that the correct digital audio volume controls are enabled in your audio device's mixer control.

- Use your audio adapter's setup or diagnostic software to test and adjust the volume of the adapter. Such software usually includes sample sounds used to test the adapter.
- Turn off your computer for 1 minute and then turn it back on. A hard reset (as opposed to pressing the Reset button or pressing Ctrl+Alt+Delete) might clear the problem.
- If your computer game lacks sound, check that it is designed to work with your audio adapter. For example, some legacy and early Windows games might require the exact settings of IRQ 7 (or IRQ 5), DMA 1, and I/O address 220 to be Sound Blaster compatible. You also might need to load DOS drivers to enable some recent sound cards to work with DOS games.

One-Sided Sound

If you hear sound coming from only one speaker, check out these possible causes:

- Are you using a mono plug in the stereo jack? A common mistake is to use a mono plug in the sound card's speaker or stereo-out jacks. Seen from the side, a stereo connector has two darker stripes. A mono connector has only one stripe.
- If you're using amplified speakers, are they powered on? Check the strength of the batteries or the AC adapter's connection to the electrical outlet. If each speaker is powered separately, be sure that both have working batteries.
- Are the speakers wired correctly? When possible, use keyed and color-coded connectors to avoid mistakes.
- Is the audio adapter driver loaded? Some sound cards provide only left-channel sound if the driver is not loaded correctly. Rerun your adapter's setup software or reinstall it in the operating system.
- Are both speakers set to the same volume? Some speakers use separate volume controls on each speaker. Balance them for best results. Separate speaker volume controls can be an advantage if one speaker must be farther away from the user than the other.
- Is the speaker jack loose? If you find that plugging your speaker into the jack properly doesn't produce sound but pulling the plug half-way out or "jimmying" it around in its hole can temporarily correct the problem, you're on the road to a speaker jack failure. There's no easy solution; buy a new adapter or whip out your soldering iron and spend a lot more time on the test bench than most audio adapters are worth. To avoid damage to the speaker jack, be sure you insert the plug straight in, not at an angle.

Volume Is Low

If you can barely hear your sound card, try these solutions:

- Are the speakers plugged into the proper jack? Speakers require a higher level of drive signal than headphones. Again, adjust the volume level in your mixer application.
- Are the mixer settings too low? Again, adjust the volume level in your mixer application. If your mixer lets you choose between speakers and headphones, be sure to select the correct speaker configuration.
- Is the initial volume too low? If your audio adapter has an external thumbwheel volume control located on the card bracket, check to ensure that it is not turned down too low.

- Are the speakers too weak? Some speakers might need more power than your audio adapter can produce. Try other speakers or put a stereo amplifier between your sound card and speakers.

Scratchy Sound

Scratchy or static-filled sound can be caused by several problems. Improving the sound can be as simple as rearranging your hardware components. The following list suggests possible solutions to the problem of scratchy sound:

- Is your audio adapter near other expansion cards? The adapter might be picking up electrical interference from other expansion cards inside the PC. Move the audio card to an expansion slot as far away as possible from other cards.
- An ISA-based audio adapter requires a lot of CPU attention. Frequent hard disk access can cause dropouts due to the CPUs switching between managing the sound card and the hard drive.
- Are your speakers too close to your monitor? The speakers can pick up electrical noise from your monitor. Move them farther away. Subwoofers should *never* be placed near the monitor because their powerful magnets can interfere with the picture. They should be on the floor to maximize low-frequency transmission.
- Are you experiencing compatibility problems between particular games and your sound card? If you notice sound problems such as stuttering voices and static on some games but not others, check with the game vendor for a software patch or with the sound card vendor for updated drivers. If the game uses DirectX, run the DXDIAG diagnostics program (select Start, Run; type **`DXDIAG`**; and click OK) and click the Sound tab. Adjust the slider for Hardware Sound Acceleration Level down one notch from Full (the default) to Standard, click Save All Information, and exit. Retry the game. If the problem persists, adjust the Hardware Sound Acceleration Level to Basic. If other games have performance problems after you adjust the Hardware Sound Acceleration Level, be sure to reset it to Full before playing those games.

Your Computer Won't Start

If your computer won't start at all, you might not have inserted the audio adapter completely into its slot. Turn off the PC and then press firmly on the card until it is seated correctly.

If you can't start your computer after installing a new sound card and its drivers, you can use the Windows "bootlog" feature to record every event during startup; this file records which hardware drivers are loaded during startup and indicates whether the file loaded successfully, didn't load successfully, or froze the computer. See the documentation for your version of Windows for details on how to create a bootlog when necessary.

Parity Errors or Other Lockups

Your computer might display a memory parity error message or simply crash. This is usually caused by resource conflicts in one of the following areas:

- IRQ
- DMA
- I/O ports

If other devices in your system are using the same resources as your audio adapter, crashes, lockups, or parity errors can result. You must ensure that multiple devices in your system do not share these resources.

Advanced Features

If you are having problems playing DVD audio, playing MP3 files, or using SPDIF connections, make sure that

- You have enabled the hardware resources on the sound card.
- You are using the correct playback program.
- Your mixer has the correct volume control setting for the device.
- Your cabling is correct for the device.

Other Problems

Sometimes sound problems can be difficult to solve. Due to quirks and problems with the way DMA is implemented in some motherboard chipsets, problems interacting with certain cards or drivers can occur. Sometimes altering the Chipset Setup options in your CMOS settings can resolve problems. These types of problems can take a lot of trial and error to solve.

The PC standard is based loosely on the cooperation among a handful of companies. Something as simple as one vendor's BIOS or motherboard design can make the standard nonstandard.

A good way to solve problems of all types with Plug and Play cards, a PnP BIOS, and a PnP operating system (Windows 9x/Me/2000) is to use the Device Manager to remove the sound card, restart the system, and allow the card's components to be redetected. This installs a "fresh" copy of the software and reinserts Registry entries.

If you are using a motherboard with a VIA chipset, be sure to download and install the latest versions of VIA drivers.

Speakers

Successful business presentations, multimedia applications, and MIDI work demand external high-fidelity stereo speakers. Although you can use standard stereo speakers, they are often too big to fit on or near your desk. Smaller bookshelf speakers are better.

Sound cards offer little or none of the amplification needed to drive external speakers. Although some sound cards have small 4-watt amplifiers, they are not powerful enough to drive quality speakers. Also, conventional speakers sitting near your display can create magnetic interference, which can distort colors and objects onscreen or jumble the data recorded on nearby floppy disks or other magnetic media.

To solve these problems, computer speakers need to be small, efficient, and self-powered. Also, they should be provided with magnetic shielding, either in the form of added layers of insulation in the speaker cabinet or electronic cancellation of the magnetic distortion.

Caution

Although most computer speakers are magnetically shielded, do not leave recorded tapes, watches, credit cards, or floppy disks in front of the speakers for long periods of time.

Quality sound depends on quality speakers. A 16-bit audio adapter might provide better sound to computer speakers, but even an 8-bit adapter sounds good from a good speaker. Conversely, an inexpensive speaker makes both 8-bit and 16-bit adapter cards sound tinny.

Now dozens of models of PC speakers are on the market, ranging from inexpensive minispeakers from Sony, Creative, and LabTech to larger self-powered models from prestigious audio companies such as Bose, Cambridge Sound Works, Klipsch, Monsoon, and Altec Lansing. Many of the medium- to higher-end speaker systems even include subwoofers to provide additional bass response. To evaluate speakers, it helps to know the jargon. Speakers are measured by three criteria:

- *Frequency response*. A measurement of the range of high and low sounds a speaker can reproduce. The ideal range is 20Hz–20KHz, the range of human hearing. No speaker system reproduces this range perfectly. In fact, few people hear sounds above 18KHz. An exceptional speaker might cover a range of 30Hz–23,000Hz, and lesser models might cover only 100Hz–20,000Hz. Frequency response is the most deceptive specification because identically rated speakers can sound completely different.
- *Total Harmonic Distortion (THD)*. An expression of the amount of distortion or noise created by amplifying the signal. Simply put, distortion is the difference between the sound sent to the speaker and the sound you hear. The amount of distortion is measured in percentages. An acceptable level of distortion is less than .1% (one-tenth of 1%). For some CD-quality recording equipment, a common standard is .05%, but some speakers have a distortion of 10% or more. Headphones often have a distortion of about 2% or less.
- *Watts*. Usually stated as watts per channel, this is the amount of amplification available to drive the speakers. Check that the company means "per channel" (or RMS) and not total power. Many audio adapters have built-in amplifiers, providing up to 8 watts per channel (most provide 4 watts). This wattage is not enough to provide rich sound, however, which is why many speakers have built-in amplifiers. With the flick of a switch or the press of a button, these speakers amplify the signals they receive from the audio adapter. If you do not want to amplify the sound, you typically leave the speaker switch set to "direct." In most cases, you'll want to amplify the signal.

Inexpensive PC speakers sometimes use batteries to power the amplifiers. Because these speakers require so much power, you might want to invest in an AC adapter or purchase speakers that use AC power. With an AC adapter, you won't have to buy new batteries every few weeks. If your speakers didn't come with an AC adapter, you can pick one up from your local Radio Shack or hardware store. Be sure that the adapter you purchase matches your speakers in voltage and polarity; most third-party adapters are multiple voltage, featuring interchangeable tips and reversible polarity.

You can control the volume and other sound attributes of your speakers in various ways, depending on their complexity and cost. Typically, each speaker has a volume knob, although some share a single volume control. If one speaker is farther away than the other, you might want to adjust the volume accordingly. Many computer speakers include a dynamic bass boost (DBB) switch. This button provides a more powerful bass and clearer treble, regardless of the volume setting. Other speakers have separate bass and treble boost switches or a three-band equalizer to control low, middle, and high frequencies. When you rely on your audio adapter's power rather than your speakers' built-in amplifier, the volume and dynamic bass boost controls have no effect. Your speakers are at the mercy of the adapter's power.

For best audio quality, adjust the master volume on the sound card near the high end and use the volume control on powered speakers to adjust the volume. Otherwise, your speakers will try to amplify any distortions coming from the low-power input from the PC's audio adapter.

An 1/8" stereo minijack connects from the audio adapter's output jack to one of the speakers. The speaker then splits the signal and feeds through a separate cable from the first speaker to the second one (often referred to as the "satellite speaker").

Before purchasing a set of speakers, check that the cables between the speakers are long enough for your computer setup. For example, a tower case sitting alongside your desk might require longer speaker wires than a desktop computer.

Beware of speakers that have a tardy built-in sleep feature. Such speakers, which save electricity by turning themselves off when they are not in use, might have the annoying habit of clipping the first part of a sound after a period of inactivity.

Speakers that are USB based will not be capable of playing CD music unless the CD-ROM drive can perform digital audio extraction. Check your drive's specifications for information.

Headphones are an option when you can't afford a premium set of speakers. Headphones also provide privacy and enable you to play your PC audio as loud as you like.

For best results with newer sound cards that support four speakers or more, check the properties sheet for the audio adapter and set whether you're using headphones, stereo speakers, or a larger number of speakers.

Make sure that speakers are placed properly. If you use a subwoofer, put it on the floor for better bass sound and to reduce EMI interference with other devices.

How can you tell whether wireless satellite speakers are causing interference? Watch your monitor; frequencies as high as 2KHz can interfere with your video display. Move the speakers away from the monitor and check the display again.

Theater and Surround Sound Considerations

If you're a serious gamer or DVD movie lover, you won't be content with ordinary stereophonic sound. Most audio adapters now support front and rear speakers, and many of the best audio adapters also support Dolby-compatible 4.1 and 5.1 speaker setups.

To ensure you get the sound you expect from four or more speakers, check the following:

- *Use the properties sheet for your audio adapter to properly describe your speaker setup.* This includes selecting the number of speakers you are using, setting options for 3D environmental audio and positional sound such as reverb, and setting up your subwoofer if present.
- *Make sure you use the correct cabling between your speakers and audio adapter.* If you are planning to use AC3/Dolby speaker setups, such as 4.1 or 5.1, be sure you use the correct S/PDIF connection and configuration. This varies from audio adapter to audio adapter; check the vendor's Web site for details.
- *Make sure you have placed your speakers correctly.* In some cases you can adjust the audio adapter's properties to improve sound quality, but sometimes you might need to move the speakers themselves.
- *Make sure you have connected your speakers to the proper jacks*. Mixing up left and right or front and rear causes poor sound quality.

Typical Speaker Setups

The simplest audio configuration available today is stereo, which uses two speakers placed to overlap sound.

Most audio adapters now support at least four speakers, but depending on the audio adapter, settings, and sound output options in the program, the rear speakers might simply mirror the front speakers' output, or you might have four distinct sound streams.

4-point surround sound uses four speakers plus a subwoofer to surround you with music and gaming sound effects; the four speakers are placed around the listener, and the subwoofer is usually placed near a wall or in the corner to amplify its low-frequency sound. The subwoofer in such setups is not on a separate circuit but is controlled by the same signals sent to the other speakers.

5.1 Surround sound, also referred to as Dolby Digital or DTS Surround sound, uses five speakers plus a subwoofer. The fifth speaker is placed between the front two speakers to fill in any missing sound caused by incorrect speaker placement. The subwoofer is independently controlled. This is the preferred sound system for use with DVD movies. Most lower-cost audio adapters lack support for 5.1 Surround sound.

Some of the latest sound cards support 7.1 Surround sound. Its configuration resembles the 5.1 Surround setup but adds left-middle and right-middle speakers that flank the listener, along with a subwoofer.

Microphones

Some audio adapters come complete with a microphone, but most do not. You'll need one to record your voice to a WAV file. Selecting a microphone is quite simple. You need one that has an 1/8" mini-jack to plug into your audio adapter's microphone, or audio in, jack. Most microphones have an on/off switch.

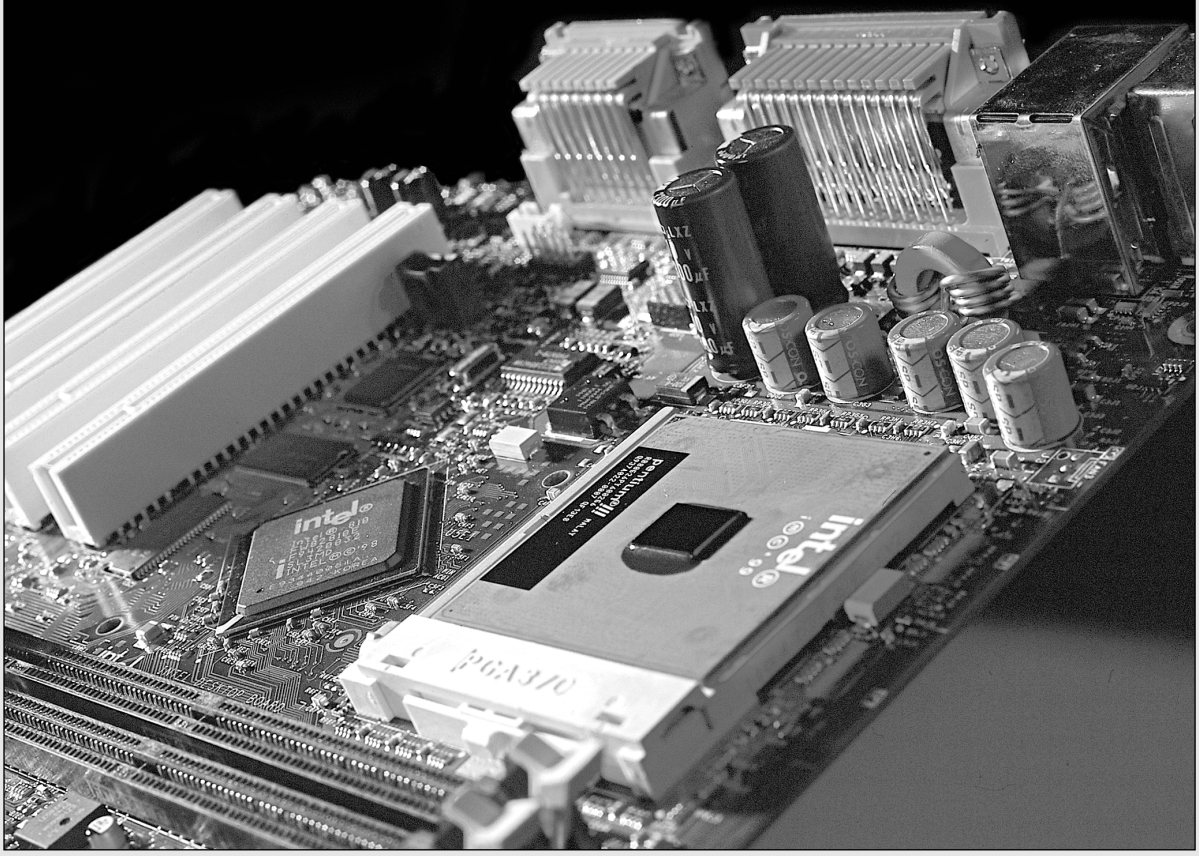
Like speakers, microphones are measured by their frequency ranges. This is not an important buying factor, however, because the human voice has a limited range. If you are recording only voices, consider an inexpensive microphone that covers a limited range of frequencies. An expensive microphone's recording capabilities extend to frequencies outside the voice's range. Why pay for something you won't be needing?

If you are recording music, invest in an expensive microphone, but be sure that your audio adapter can do justice to the signal produced by the microphone. A high-quality microphone can produce mediocre results when paired with a cheap 8-bit audio adapter.

Your biggest decision is to select a microphone that suits your recording style. If you work in a noisy office, you might want a unidirectional microphone that will prevent extraneous noises from being recorded. An omnidirectional microphone is best for recording a group conversation.

Most higher-priced audio adapters include a microphone of some type. This can be a small lapel microphone, a handheld microphone, or one with a desktop stand. If you want to keep your hands free, you might want to shun the traditional handheld microphone for a lapel or desktop model. If your audio adapter does not come with a microphone, see your local stereo or electronics parts store. Be sure that any microphone you purchase has the correct impedance to match the audio adapter's input.

If you're using software such as L & H's Voice Express series, Dragon Naturally Speaking, IBM Via Voice, Philips FreeSpeech, or other voice-recognition software, use the microphone supplied with the software or choose from alternative models the software vendor recommends. Run the microphone setup program again if your software has trouble recognizing your voice. Some newer models feature a battery pack to boost sound quality; be sure to check the batteries and replace them to keep recognition quality high.



If you're talking but your voice-recognition or recording software isn't responding, check the following:

- *Incorrect jack*. It's easy to plug the microphone into the wrong jack. Try using a magic marker to color-code the microphone wire and jack to make matching up easier.

- *Check the recording volume in the mixer control.* This usually defaults to Mute to avoid spurious noise.
- *Make sure the microphone is on in the voice-recognition or recording software.* You must click the Record button in recording software, and many voice-recognition programs let you "pick up" the microphone for use or "put it down" when you need to answer the phone. Look for an onscreen microphone icon in the Windows System Tray for fast toggling between modes.

CHAPTER 17

I/O Interfaces from Serial and Parallel to IEEE-1394 and USB

Introduction to Input/Output Ports

This chapter covers the primary peripheral input/output ports on a modern PC system. This includes a discussion of both the so-called "legacy" serial and parallel ports that have been standard on PCs since the beginning, as well as a discussion of the more current Universal Serial Bus (USB), which is replacing both serial and parallel ports, and IEEE-1394 (i.Link or FireWire) interfaces. (IEEE stands for the Institute of Electrical and Electronic Engineers.) Although SCSI and IDE are also I/O interfaces, they are mainly used as internal interfaces and are important or complicated enough to warrant their own chapters for more specific and detailed coverage.

USB and IEEE-1394 (i.Link or FireWire)

The two most popular high-speed serial-bus architectures for desktop and portable PCs are Universal Serial Bus (USB) and IEEE-1394, which is also called i.Link or FireWire. These are high-speed communications ports that far outstrip the capabilities of older standard serial and parallel ports. They can also be used as an alternative to SCSI for high-speed external peripheral connections. In addition to performance, these newer ports offer I/O device consolidation, which means that all types of external peripherals can connect to these ports.

Why Serial?

The recent trend in high-performance peripheral bus design is to use a serial architecture, in which 1 bit at a time is sent down a wire. Because parallel architecture uses 8, 16, or more wires to send bits simultaneously, the parallel bus is actually much faster at the same clock speed. However, increasing the clock speed of a serial connection is much easier than increasing that of a parallel connection.

Parallel connections in general suffer from several problems, the biggest being signal skew and jitter. Skew and jitter are the reasons high-speed parallel buses such as SCSI (small computer systems interface) are limited to short distances of 3 meters or less. The problem is that, although the 8 or 16 bits of data are fired from the transmitter at the same time, by the time they reach the receiver, propagation delays have conspired to allow some bits to arrive before the others. The longer the cable, the longer the time between the arrival of the first and last bits at the other end! This *signal skew*, as it is called, prevents you from running a high-speed transfer rate or a longer cable—or both. *Jitter* is the tendency for the signal to reach its target voltage and float above and below for a short period of time.

With a serial bus, the data is sent 1 bit at a time. Because there is no worry about when each bit will arrive, the clocking rate can be increased dramatically. For example, the top transfer rate possible with EPP/ECP parallel ports is 2MBps, whereas IEEE-1394 ports (which use high-speed serial technology) support transfer rates as high as 400Mbps (about 50MBps)—25 times faster than parallel ports. USB 2.0 supports transfer rates of 480Mbps (about 60MBps), which is about 30 times faster than the venerable parallel printer port!

At high clock rates, parallel signals tend to interfere with each other. Serial again has an advantage because, with only one or two signal wires, crosstalk and interference between the wires in the cable are negligible.

In general, parallel cabling is more expensive than serial cabling. Besides the many additional wires needed to carry the multiple bits in parallel, the cable also must be specially constructed to prevent crosstalk and interference between adjacent data lines. This is one reason external SCSI cables are so expensive. Serial cabling, by comparison, is very inexpensive. For one thing, it has significantly fewer wires. Furthermore, the shielding requirements are far simpler, even at very high speeds. Because of this, transmitting serial data reliably over longer distances is also easier, which is why parallel interfaces have shorter recommended cable lengths than do serial interfaces.

For these reasons—in addition to the need for new Plug and Play external peripheral interfaces and the elimination of the physical port crowding on portable computers—these high-performance serial buses were developed. USB is a standard feature on virtually all PCs today; is used for most general-purpose, high-speed external interfacing; and is the most compatible, widely available, and fastest general-purpose external interface. In addition, IEEE-1394 (more commonly known as FireWire), although mainly used in certain niche markets—such as connecting DV (digital video) camcorders—is also spreading into other high-bandwidth uses, such as high-resolution scanners and external hard drives.

Universal Serial Bus

Universal Serial Bus (USB) is an external peripheral bus standard designed to bring Plug and Play capability for attaching peripherals externally to the PC. USB eliminates the need for special-purpose ports, reduces the need to use special-purpose I/O cards, (thus reducing the need to reconfigure the system with each new device added), and saves important system resources such as interrupts (IRQs); regardless of the number of devices attached to a system's USB ports, only one IRQ is required. PCs equipped with USB enable peripherals to be automatically recognized and configured as soon as they are physically attached, without the need to reboot or run setup. USB allows up to 127 devices to run simultaneously on a single bus, with peripherals such as monitors and keyboards acting as additional plug-in sites, or hubs. USB cables, connectors, hubs, and peripherals can be identified by icons, as shown in Figure 17.1. Note the "plus" symbol added to the upper icon, which indicates that port supports USB 2.0 (Hi-Speed USB) in addition to the standard 1.x support.

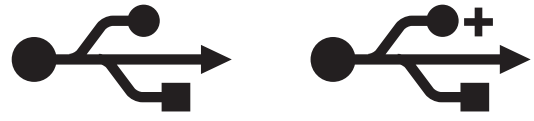


Figure 17.1 These icons identify USB cables, connectors, hubs, and peripherals.

Intel has been the primary proponent of USB, and all its PC chipsets starting with the PIIX3 South Bridge chipset component (introduced in February 1996) have included USB support as standard. Other chipset vendors have followed suit, making USB as standard a feature of today's desktop and notebook PCs as the serial and parallel ports once were.

Six other companies initially worked with Intel in co-developing the USB, including Compaq, Digital, IBM, Microsoft, NEC, and Northern Telecom. Together, these companies have established the USB Implementers Forum (USB-IF) to develop, support, and promote USB architecture.

◀◀ See "Chipsets," p. 232.

The USB-IF formally released USB 1.0 in January 1996, USB 1.1 in September 1998, and USB 2.0 in April 2000. The 1.1 revision was mostly a clarification of some issues related to hubs and other areas of the specification. Most devices and hubs should be 1.1 compliant, even if they were manufactured before the release of the 1.1 specification. The biggest change was USB 2.0, which is 40 times faster than the original USB and yet fully backward compatible. USB ports can be retrofitted to older computers that lack built-in USB connectors through the use of either an add-on PCI card (for desktop computers) or a PC Card on Cardbus-compatible notebook computers. You can also use USB add-on cards to update an older system that has only USB 1.1 on the motherboard. As of mid-2002, virtually all motherboards include four or more USB 2.0 ports as standard.

USB Technical Details

USB 1.1 runs at 12Mbps (1.5MBps) over a simple four-wire connection. The bus supports up to 127 devices connected to a single root hub and uses a tiered-star topology, built on expansion hubs that can reside in the PC, any USB peripheral, or even standalone hub boxes. Note that although the standard allows up to 127 devices to be attached, they all must share the 1.5MBps bandwidth, meaning that for every active device you add, the bus will slow down some. In practical reality, few people will have more than 8 devices attached at any one time.

For low-speed peripherals, such as pointing devices and keyboards, the USB also has a slower 1.5Mbps subchannel. The subchannel connection is used for slower interface devices, such as keyboards and mice.

USB employs what is called Non Return to Zero Invert (NRZI) data encoding. NRZI is a method of encoding serial data in which 1s and 0s are represented by opposite and alternating high and low voltages where there is no return to a zero (or reference) voltage between the encoded bits. In NRZI encoding, a 1 is represented by no change in signal level, and a 0 is represented by a change in level. A string of 0s causes the NRZI data to toggle each bit time; a string of 1s causes long periods with no transitions in the data. This is an efficient transfer encoding scheme because it eliminates the need for additional clock pulses that would otherwise waste time and bandwidth.

USB devices are considered either *hubs* or *functions*, or both. Functions are the individual devices that attach to the USB, such as a keyboard, mouse, camera, printer, telephone, and so on. Hubs provide additional attachment points to the USB, enabling the attachment of more hubs or functions. The initial ports in the PC system unit are called the *root hub*, and they are the starting point for the USB. Most motherboards have two, three, or four USB ports, any of which can be connected to functions or additional hubs. Some systems place one or two of the USB ports in the front of the computer, which is very convenient for devices you use only occasionally, such as digital cameras or flash memory card readers.

Hubs are essentially wiring concentrators, and through a star-type topology they allow the attachment of multiple devices. Each attachment point is referred to as a *port*. Most hubs have either four or eight ports, but more are possible. For more expandability, you can connect additional hubs to the ports on an existing hub. The hub controls both the connection and distribution of power to each of the connected functions. A typical hub is shown in Figure 17.2.

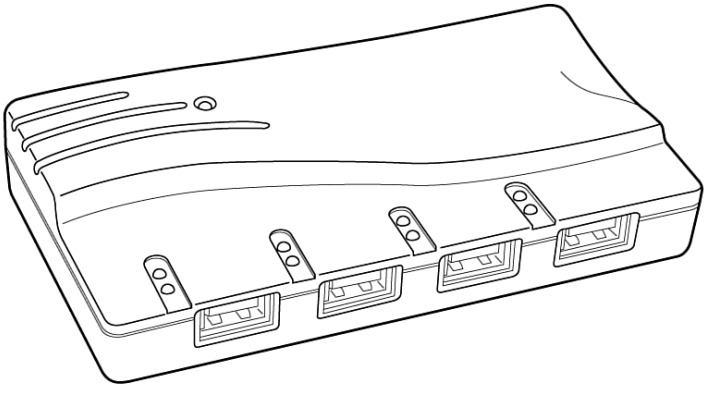

Figure 17.2 A typical USB hub with eight ports.

Besides providing additional sockets for connecting USB peripherals, a hub provides power to any attached peripherals. A hub recognizes the dynamic attachment of a peripheral and provides at least 0.5W of power per peripheral during initialization. Under control of the host PC driver software, the hub can provide more device power, up to a maximum of 2.5W, for peripheral operation.

Tip

For the most reliable operation, I recommend that you use self-powered hubs, which plug into an AC adapter. Bus-powered hubs pull power from the PC's USB root hub connector and aren't always capable of providing adequate power for high-power requirement devices, such as optical mice.

A newly attached hub is assigned a unique address, and hubs can be cascaded up to five levels deep (see Figure 17.3). A hub operates as a bidirectional repeater and repeats USB signals as required both upstream (toward the PC) and downstream (toward the device). A hub also monitors these signals and handles transactions addressed to itself. All other transactions are repeated to attached devices. A USB 1.1 hub supports both 12Mbps (full-speed) and 1.5Mbps (low-speed) peripherals.

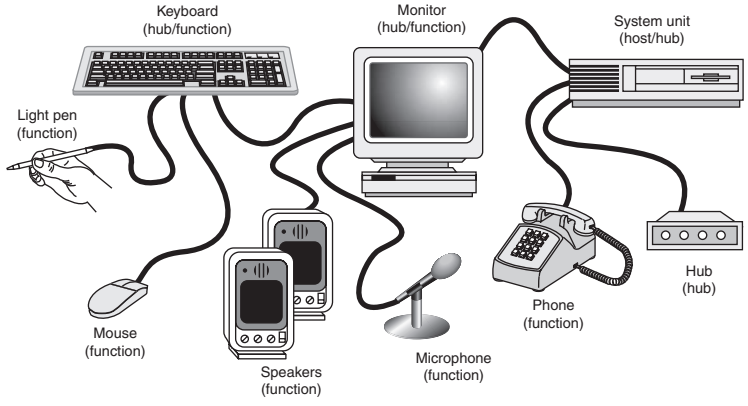

Figure 17.3 A typical PC with USB devices can use multiple USB hubs to support a variety of peripherals, connected to whichever hub is most convenient.

Maximum cable length between two full-speed (12Mbps) devices or a device and a hub is 5 meters using twisted-pair shielded cable with 20-gauge wire. Maximum cable length for low-speed (1.5Mbps) devices using non-twisted-pair wire is 3 meters. These distance limits are shorter if smaller-gauge wire is used (see Table 17.1).

Table 17.1 Maximum Cable Lengths Versus Wire Gauge

Gauge	Resistance (in Ohms/Meter W/m)	Length (Max.)
28	0.232 Ω/m	0.81m
26	0.145 Ω/m	1.31m
24	0.091 Ω/m	2.08m
22	0.057 Ω/m	3.33m
20	0.036 Ω/m	5.00m

Although USB 1.1 is not as fast at data transfer as FireWire or SCSI, it is still more than adequate for the types of peripherals for which it is designed. USB 2.0 operates a surprising 40 times faster than USB 1.1 and allows transfer speeds of 480Mbps or 60MBps. Because it is fully backward-compatible and supports older 1.1 devices, I recommend purchasing only motherboards and add-in USB cards that conform to the faster USB 2.0 (Hi-Speed USB) standard. One of the additional benefits of USB 2.0 is the capability to handle concurrent transfers, which enables your USB 1.1 devices to transfer data at the same time without tying up the USB bus.

USB 2.0 drivers were not provided with the initial launch of Windows XP but are available through system update downloads or service packs. Use the Windows Update feature to connect to the Microsoft site and download any updates as necessary. Add-on USB 2.0 cards might include their own drivers, which should be installed.

USB Connectors

Four main styles of connectors are specified for USB, called Series A, Series B, Mini-A, and Mini-B connectors. The A connectors are used for upstream connections between a device and the host or a hub. The USB ports on motherboards and hubs are usually Series A connectors. Series B connectors are designed for the downstream connection to a device that has detachable cables. In all cases, the mini connectors are simply smaller versions of the larger ones, in a physically smaller form factor for smaller devices.

The physical USB plugs are small (especially the mini plugs) and, unlike a typical serial or parallel cable, the plug is not attached by screws or thumbscrews. There are no pins to bend or break, making USB devices very user friendly to install and remove. The USB plug shown in Figure 17.4 snaps into place on the USB connector.

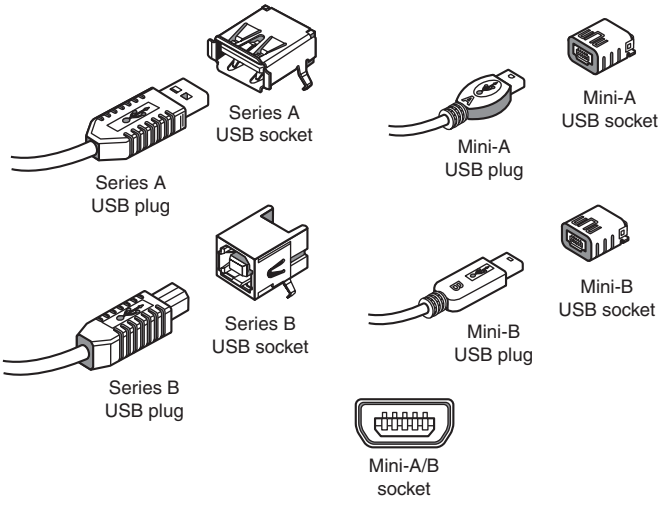

Figure 17.4 USB Series A and Series B plugs and receptacles.

Note that a Mini-A/B socket is a dual-purpose socket that can accept either Mini-A or Mini-B plugs. The newer mini plugs and sockets have plastic portions inside the connectors that are required to be color-coded as shown in Table 17.2.

Table 17.2 Color-Coding for USB Mini-Plugs and Sockets

Connector	Color
Mini-A socket	White
Mini-A plug	White
Mini-B socket	Black
Mini-B plug	Black
Mini-A/B socket	Gray

Tables 17.3 and 17.4 show the pinouts for the USB connectors and cables. Most systems with USB connectors feature one or two pairs of Series A plugs on the rear of the system. Some also feature one or two pairs on the front of the system for ease of use with items that are not permanently connected.

Table 17.3 USB Connector Pinouts for Series A/B Connectors

Pin	Signal Name	Wire Color	Comment
1	Vbus	Red	Bus power
2	- Data	White	Data transfer
3	+ Data	Green	Data transfer
4	Ground	Black	Cable ground
Shell	Shield	—	Drain wire

Table 17.4 USB Connector Pinouts for Mini-A/B Connectors

Pin	Signal Name	Wire Color	Comment
1	Vbus	Red	Bus power
2	- Data	White	Data transfer
3	+ Data	Green	Data transfer
4	ID	—	A/B identification*
4	Ground	Black	Cable ground
Shell	Shield	—	Drain wire

**Used to identify a Mini-A from a Mini-B connector to the device. ID is connected to Ground in a Mini-A plug and not connected (open) in a Mini-B plug.*

USB conforms to Intel's Plug and Play (PnP) specification, including hot plugging, which means that devices can be plugged in dynamically without powering down or rebooting the system. Simply plug in the device, and the USB controller in the PC detects the device and automatically determines and allocates the required resources and drivers. Microsoft has developed USB drivers and included them automatically in Windows 98 and later.

Windows 95B and 95C have very limited support for USB 1.1; the necessary drivers are not present in the original Windows 95 or 95A. With Windows 95B, the USB drivers are not automatically included; they are provided separately, although a late release of Windows 95—Windows 95C—includes USB support. Many USB devices will not work with **any** Windows 95 release, including those that have the USB support files included.

Windows 98 and later have USB 1.1 support built in; however, additional drivers are required for USB 2.0 or later. In most cases, these drivers can be downloaded from Microsoft using the Windows Update feature.

USB support is also required in the BIOS for devices such as keyboards and mice. This is included in all newer systems with USB ports built in. Aftermarket PCI and PC Card boards also are available for adding USB to systems that don't include it as standard on the motherboard. USB peripherals include printers, CD-ROMs, modems, scanners, telephones, joysticks, keyboards, and pointing devices such as mice and trackballs.

A free utility called USBready is available from `http://www.usb.org`; it examines your PC's hardware and software and informs you of your PC's USB capabilities. Most PCs built in 1995 or earlier don't support USB. During 1996 most PC motherboards began supporting USB, and if your system dates from 1997 to 1998 or later, USB support is almost a certainty.

One interesting feature of USB is that, with certain limitations, attached devices can be powered by the USB bus. The PnP aspects of USB enable the system to query the attached peripherals as to their power requirements and issue a warning if available power levels are being exceeded. This is important for USB when it is used in portable systems because the battery power that is allocated to run the external peripherals might be limited.

To avoid running out of power when connecting USB devices, use a self-powered hub.

Another of the benefits of the USB specification is the self-identifying peripheral, a feature that greatly eases installation because you don't have to set unique IDs or identifiers for each peripheral—the USB handles that automatically. Also, USB devices can be "hot" plugged or unplugged, meaning that you do not have to turn off your computer or reboot every time you want to connect or disconnect a peripheral.

Enabling USB Support

Many systems shipped before Windows 98 was introduced in mid-1998 have onboard USB ports that were disabled at the factory. In some cases, especially with Baby-AT motherboards, there is no way to tell from the outside which systems have USB support built in. This is because many of these same systems were not shipped with the USB header cables necessary to bring the USB root hub connectors from the motherboard to the rear of the system.

If USB support is disabled in the system BIOS, restart your system and locate the BIOS setup screen that refers to the USB ports. Enable the USB feature. If you see a separate entry for USB IRQ, enable this as well. After you restart the computer with a USB-aware operating system, your "new" USB root hub will be detected and the drivers will be installed if you are using Windows 98 or newer; you might need to manually install drivers with late releases of Windows 95.

If your system has USB connectors present, you also will be able to use the "new" USB ports as soon as the system is rebooted after the USB drivers are installed. However, if your motherboard vendor didn't provide USB connectors, you must buy USB header cables. Before you order them, check the configuration of your motherboard's USB header pins. The standard is two rows of five pins each. Companies such as Belkin, CyberGuys, and Cables To Go sell header cables that are compatible with standard USB header pins if your motherboard supplier doesn't have the header cable in stock. Figure 17.5 shows a typical USB header cable set.

One of the biggest advantages of an interface such as USB is that it requires only a single interrupt (IRQ) from the PC. Therefore, you can connect up to 127 devices and they will not use separate interrupts, as they might if each were connected over a separate interface. This is a major benefit of the USB interface.

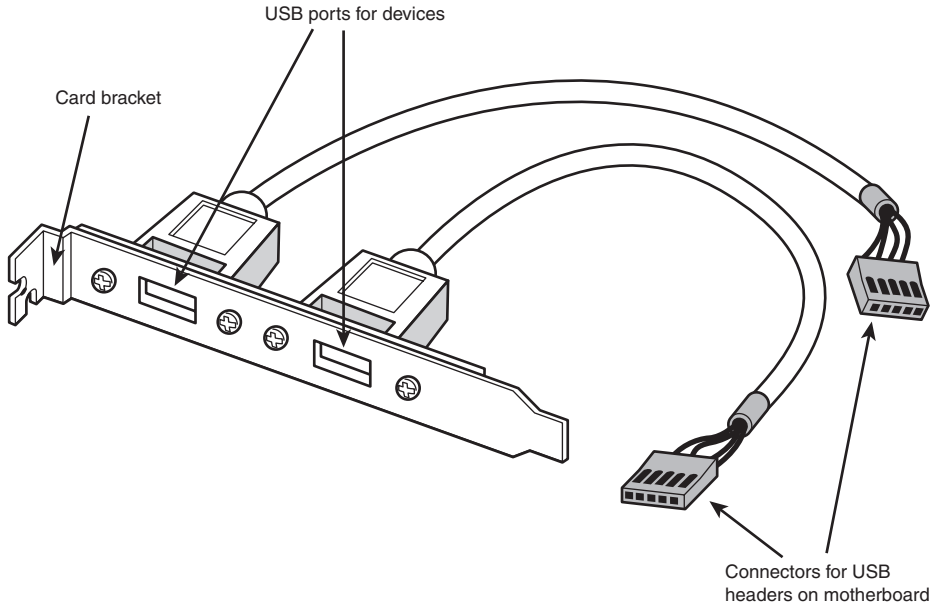

Figure 17.5 A typical USB header cable set; plug it into your motherboard to connect devices to the additional onboard USB ports (if present).

Some unique USB devices are available, including USB-to-serial, USB-to-parallel, USB-to-Ethernet, USB-to-SCSI, USB-to-PS/2 (standard keyboard and mouse port), and even direct-connect USB bridges (which allow two systems to be connected together via USB for data transfers using Direct Cable Connection or similar programs). USB-to-serial or USB-to-parallel converters provide an easy way to connect legacy RS232 or Centronics parallel interface peripherals, such as modems and printers, to a USB port. USB-to-Ethernet adapters provide a LAN connection through a USB port. Drivers supplied with these devices enable them to fully emulate standard devices.

USB 2.0

USB 2.0 is a backward-compatible extension of the USB 1.1 specification that uses the same cables, connectors, and software interfaces, but it runs 40 times faster than the original 1.0 and 1.1 versions. The higher speed enables higher-performance peripherals, such as higher-resolution Web/videoconferencing cameras, scanners, and faster printers, to be connected externally with the same easy plug-and-play installation of current USB peripherals. From the end-user point of view, USB 2.0 works exactly the same as 1.1—only faster and with more interesting, higher-performance devices available. All existing USB 1.1 devices work in a USB 2.0 bus because USB 2.0 supports all the slower-speed connections. USB data rates are shown in Table 17.5.

Table 17.5 USB Data Rates

Interface	Megabits per Second	Megabytes per Second
USB 1.1 low speed	1.5Mbit/sec	0.1875MB/sec
USB 1.1 high speed	12Mbit/sec	1.5MB/sec
USB 2.0	480Mbit/sec	60MB/sec

The support of higher-speed USB 2.0 peripherals requires using a USB 2.0 hub. You can still use older USB 1.1 hubs on a 2.0 bus, but any peripherals or additional hubs connected downstream from a 1.1 hub will operate at the slower 1.5MBps USB 1.1 maximum speed. Devices connected to USB 2.0 hubs will operate at the maximum speed of the device, up to the full USB 2.0 speed of 60MBps. The higher transmission speeds through a 2.0 hub are negotiated on a device-by-device basis, and if the higher speed is not supported by a peripheral, the link operates at a lower USB 1.1 speed.

As such, a USB 2.0 hub accepts high-speed transactions at the faster USB 2.0 frame rate and must deliver them to high-speed USB 2.0 peripherals as well as USB 1.1 peripherals. This data rate matching responsibility requires increased complexity and buffering of the incoming high-speed data. When communicating with an attached USB 2.0 peripheral, the 2.0 hub simply repeats the high-speed signals; however, when communicating with USB 1.1 peripherals, a USB 2.0 hub buffers and manages the transition from the high speed of the USB 2.0 host controller (in the PC) to the lower speed of a USB 1.1 device. This feature of USB 2.0 hubs means that USB 1.1 devices can operate along with USB 2.0 devices and not consume any additional bandwidth. USB 2.0 devices and root hubs are not yet widely available, but they are slowly being introduced by manufacturers. USB 2.0 devices, unlike USB 1.1 devices, might be located inside your system. Some manufacturers of add-on USB 2.0 cards are equipping the cards with both external and internal USB 2.0 ports.

How can you tell which devices are designed to support USB 1.1 and which support the emerging USB 2.0 standard? The USB Implementer's Forum (USB-IF), which owns and controls the USB standard, introduced new logos in late 2000 for products that have passed its certification tests. The new logos are shown in Figure 17.6.

Figure 17.6 The new USB-IF USB 1.1-compliant logo (left) compared to the new USB-IF USB 2.0-compliant logo (right).

As you can see from Figure 17.9, USB 1.1 will be called simply "USB," and USB 2.0 will now be called "Hi-Speed USB." Also note the icons shown earlier, where the addition of the plus symbol to the standard USB trident is used to identify ports that support USB 2.0.

USB On-The-Go

In December 2001, the USB-IF released a supplement to the USB 2.0 standard called USB On-The-Go. It was designed to address the one major shortcoming of USB: the fact that a PC was required to transfer data between two devices. In other words, you couldn't connect two cameras together and transfer pictures between them without a PC orchestrating the transfer. With USB On-The-Go, however, devices that conform to the specification still work normally when they are connected to a PC, but they also have additional capabilities when connected to other devices supporting the standard.

Although this capability can also work with PC peripherals, it was mainly added to address issues using USB devices in the consumer electronics area, where a PC might not be available. Using this standard, devices such as digital video recorders can connect to other recorders to transfer recorded movies or shows, items such as personal organizers can transfer data to other organizers, and so on.

The addition of the On-The-Go supplement to USB 2.0 greatly enhances the use and capabilities of USB both in the PC and consumer electronics markets.

USB Adapters

If you still have a variety of older peripherals and yet you want to take advantage of the USB connector on your motherboard, several signal converters or adapters are available. Companies such as Belkin and others currently have adapters in the following types:

- USB-to-parallel (printer)
- USB-to-serial
- USB-to-SCSI
- USB-to-Ethernet
- USB-to-keyboard/mouse
- USB-to-TV/video

These adapters usually look just like a cable, with a USB connector at one end (which you plug into your USB port) and various other interface connectors at the other end. There is more to these devices than just a cable: Active electronics are hidden in a module along the cable or are sometimes packed into one of the cable ends. The electronics is powered by the USB bus and converts the signals to the appropriate other interface. Some drawbacks do exist to these adapters. One is cost: They typically cost $50–$100 or more. It can be tough to spend $70 on a USB-to-parallel adapter to drive a printer that barely cost twice that amount. In addition, other limitations might apply. For example, USB-to-parallel converters work only with printers and not other parallel-connected devices, such as scanners, cameras, external drives, and so on. Before purchasing one of these adapters, ensure that it will work with the device or devices you have in mind. If you need to use more than one non-USB device with your system, consider special USB hubs that also contain various combinations of other port types. These special hubs are more expensive than USB-only hubs but are less expensive than the combined cost of a comparable USB hub and two or more USB adapters.

Another type of adapter available is a direct-connect cable, which enables you to connect two USB-equipped PCs directly together using USB as a network. These are popular for people playing two-player games, with each player on his own system. Another use is for transferring files because this connection usually works as well or better than the direct parallel connection that otherwise might be used. Also available are USB switchboxes that enable one peripheral to be shared among two or more USB buses. Note that both the direct connect cables and USB switchboxes are technically not allowed as a part of the USB specification, although they do exist.

Legacy-Free PCs

USB adapters might find more use in the future as more and more legacy-free PCs are shipped. A *legacy-free PC* is one that lacks any components that were connected to or a part of the traditional ISA bus. This especially includes the otherwise standard Super I/O chip, which integrated serial, parallel, keyboard, mouse, floppy, and other connections. A legacy-free motherboard therefore does not have the standard serial, parallel, and keyboard/mouse connectors on the back and lacks an integrated floppy controller. The devices previously connected to those ports must instead be connected via USB, ATA/IDE, PCI, and other interfaces.

Legacy-free systems are primarily found on the low-end, consumer-oriented systems. For those systems, USB will likely be one of the only external connections provided. To compensate for the loss of the other external interfaces, most legacy-free motherboards feature four or more integrated USB connectors on one or two buses.

IEEE-1394

The *Institute of Electrical and Electronic Engineers* Standards Board introduced IEEE-1394 (or just 1394 for short) in late 1995. The number comes from the fact that this happened to be the 1,394th standard they published. It is the result of the large data-moving demands of today's audio and video multimedia devices. The key advantage of 1394 is that it's extremely fast; the current standard supports data transfer rates up to an incredible 400Mbps.

1394 Standards

The current version of the 1394 standard is actually referred to as 1394a, or sometimes as 1394a-2000 for the year it was adopted. The 1394a standard was introduced to solve interoperability and compatibility issues in the original 1394 standard; it uses the same connectors and supports the same speeds as the original 1394 standard.

The proposed 1394b standard is expected to support transfer rates of 1,600Mbps; future versions of the standard might reach speeds of up to 3,200Mbps. 1394b will be capable of reaching much higher speeds than the current 1394/1394a standard because it will also support network technologies such as glass and plastic fiber-optic cable and Category 5 UTP cable, increased distances when Category 5 cabling is used between devices, and improvements in signaling. 1394b will also be fully backward-compatible with 1394a devices. 1394 is also known by two other common names: i.Link and FireWire. *i.Link* is an IEEE-1394 designation initiated by Sony in an effort to put a more user-friendly name on IEEE-1394 technology. Most companies that produce 1394 products for PCs have endorsed this new name initiative. The term *FireWire* is an Apple-specific trademark. Companies that want to include the FireWire name in a 1394 product first must sign a licensing agreement with Apple (and pay the necessary royalties)—something that is not required with USB, which Intel licenses on a royalty-free basis.

1394 Technical Details

The IEEE-1394a standard currently exists with three signaling rates—100Mbps, 200Mbps, and 400Mbps (12.5MBps, 25MBps, and 50MBps). Most PC adapter cards support the 200Mbps (25MBps) rate, even though current devices generally operate at only 100Mbps (12.5MBps). A maximum of 63 devices can be connected to a single IEEE-1394 adapter card by way of daisy-chaining or branching. 1394 devices, unlike USB devices, can be used in a daisy-chain without using a hub, although hubs are recommended for devices that will be hot-swapped. Cables for IEEE-1394 devices use Nintendo GameBoy–derived connectors and consist of six conductors: Four wires transmit data, and two wires conduct power. Connection with the motherboard is made either by a dedicated IEEE-1394 interface or by a PCI adapter card. Figure 17.7 shows the 1394 cable, socket, and connector.

The 1394 bus was derived from the FireWire bus originally developed by Apple and Texas Instruments, and it is also a part of a new Serial SCSI standard.

1394 uses a simple six-wire cable with two differential pairs of clock and data lines, plus two power lines; the four-wire cable shown in Figure 17.7 is used with self-powered devices, such as DV camcorders. Just as with USB, 1394 is fully PnP, including the capability for hot-plugging (insertion and removal of components without powering down). Unlike the much more complicated parallel SCSI bus, 1394 does not require complicated termination, and devices connected to the bus can draw up to 1.5 amps of electrical power. 1394 offers equal or greater performance compared to ultra-wide SCSI, with a much less expensive and less complicated connection.

1394 is built on a daisy-chained and branched topology, and it allows up to 63 nodes, with a chain of up to 16 devices on each node. If this is not enough, the standard also calls for up to 1,023 bridged buses, which can interconnect more than 64,000 nodes! Additionally, as with SCSI, 1394 can support devices with various data rates on the same bus. Most 1394 adapters have three nodes, each of which can support 16 devices in a daisy-chain arrangement. Some 1394 adapters also support internal 1394 devices.

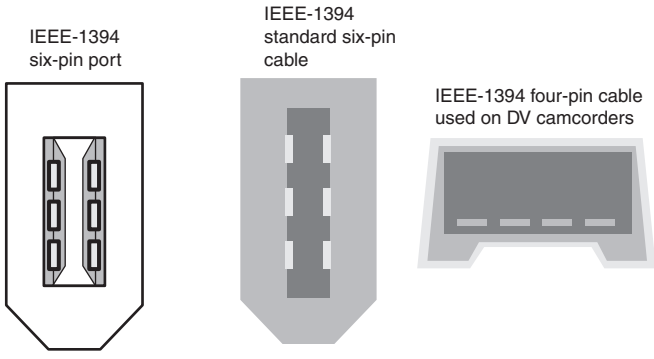

Figure 17.7 IEEE-1394 port, 6-pin cable, and 4-pin cable.

The types of devices that can be connected to the PC via 1394 mainly include video cameras; editing equipment; and all forms of disk drives, including hard disk, optical, floppy, CD-ROM, and DVD-ROM drives. Also, digital cameras, tape drives, high-resolution scanners, and many other high-speed peripherals that feature 1394 have interfaces built in. The 1394 bus appears in some desktop and portable computers as a replacement or supplement for other external high-speed buses, such as USB or SCSI.

Chipsets and PCI adapters for the 1394 bus are available from a number of manufacturers, including some models that support both 1394 and other port types in a single slot. Microsoft has developed drivers to support 1394 in Windows 9x and later, including Windows XP. The most popular devices that conform to the IEEE-1394 standard are camcorders and VCRs with digital video capability. Sony was among the first to release such devices (under the i.Link name). In typical Sony fashion, however, its products have a unique four-wire connector that requires an adapter cord to be used with IEEE-1394 PC cards, and Sony doesn't even call it IEEE-1394 or FireWire—it created its own designation (i.Link) instead. DV products using 1394 also are available from Panasonic, Sharp, Matsushita, and others. Non-computer IEEE-1394 applications include DV conferencing devices, satellite audio and video data streams, audio synthesizers, DVD, and other high-speed disc drives.

Because of the current DV emphasis for IEEE-1394 peripherals, many FireWire cards currently offered are bundled with DV capturing and editing software. With a DV camera or recording equipment, these items provide substantial video editing and dubbing capabilities on your PC. Of course, you need IEEE-1394 I/O connectivity, which is a growing, but still somewhat rare, feature on current motherboards.

Comparing IEEE-1394a and USB 1.1/2.0

Because of the similarity in both the form and function of USB and 1394, there has been some confusion about the two. Table 17.6 summarizes the differences between the two technologies.

Table 17.6 IEEE-1394a and USB Comparison

	IEEE-1394a (a.k.a. i.Link; FireWire)	USB 1.1	USB 2.0
PC-host required	No	Yes	Yes/No*
Maximum number of devices	63	127	127
Hot-swappable	Yes	Yes	Yes
Maximum cable length between devices	4.5 meters	5 meters	5 meters
Transfer rate	200Mbps (25MBps)	12Mbps (1.5MBps)	480Mbps (60MBps)
Proposed future transfer rates	400Mbps (50MBps) 800Mbps (100MBps) 1Gbps+ (125MBps+)	None	None
Typical devices	DV camcorders; high-res digital cameras; HDTV; set-top boxes; high-speed drives; high-res scanners; electronic musical instruments	Keyboards; mice; joysticks; low-res digital cameras; low-speed drives; modems; printers; low-res scanners	All USB 1.1 devices, plus DV camcorders; high-res digital cameras; HDTV; set-top boxes; high-speed drives; high-res scanners

**No with USB On-The-Go.*

Because the overall performance and physical specifications are similar, the main difference between USB and 1394 is popularity. The bottom line is that USB is by far the most popular external interface for PCs, eclipsing all others by comparison. This is primarily because Intel developed most of USB and has placed built-in USB support in all its motherboard chipsets and motherboards since 1996. Virtually no motherboard chipsets integrate 1394; in most cases, it has to be added as an extra-cost chip to the motherboard. The cost of the additional 1394 circuitry (plus the Apple royalties) and the fact that all motherboards already have USB, have greatly limited the popularity of 1394 (FireWire) in the PC marketplace.

Even with the overwhelming popularity of USB, a market for 1394 still exists. Perhaps the main reason 1394 will survive in conjunction with the USB 2.0 interface is that USB is normally PC-centric, whereas 1394 is not. In other words, USB requires a PC as the host, whereas 1394 can connect two devices directly without a PC between them. As such, 1394 can be used to directly connect a DV camcorder to a DV-VCR for dubbing tapes or editing.

Even this has changed, however, as a supplement called USB On-The-Go was added to the USB 2.0 specification in December 2001. USB On-The-Go enables the same device-to-device connections as was capable in 1394 (FireWire) and essentially nullifies the one advantage 1394 had over USB. Because of the popularity and capabilities of USB, I recommend seeking out only USB peripherals over their 1394 (FireWire) counterparts where possible.

Many people like to bring any comparison of USB and 1394 down to speed, but that is a constantly changing parameter. 1394a offers a data transfer rate more than 33 times faster than that of USB 1.1, but most FireWire ports don't run at the full rated speed. At full speed, 1394a is about 83% as fast as USB 2.0. This speed differential will change again in the future as higher-speed versions of 1394 debut (such as the proposed 1394b with its 1.6Mbps initial speed rating), but for now USB is clearly in the lead.

Because both USB and 1394 (FireWire) offer relatively close to the same overall capabilities and performance, you make your choice based on which devices you intend to connect. If the digital video camera you want to connect has only a 1394 (FireWire/i.Link) connection, you will need to add a 1394 FireWire card to your system, if such a connection isn't already present on your motherboard. Most general-purpose PC storage, I/O, and other devices are USB, whereas only video devices usually have 1394 connections. Because USB is built into virtually all PCs, I recommend seeking out only USB devices over those that have a 1394 FireWire connection.

Standard Serial and Parallel Ports

Traditionally, the most basic communications ports in any PC system have been the serial and parallel ports, and these ports continue to be important.

Serial ports (also known as *communication* or *COM* ports) originally were used for devices that had to communicate bidirectionally with the system. Such devices include modems, mice, scanners, digitizers, and any other devices that "talk to" and receive information from the PC. Newer parallel port standards now allow the parallel port to perform high-speed bidirectional communications.

Several companies manufacture communications programs that perform high-speed transfers between PC systems using serial or parallel ports. Versions of these file transfer programs have been included with DOS 6.0 and higher (Interlink) and with Windows 95 and newer versions (Direct Cable Connection [DCC]). Currently, numerous products are on the market that make nontraditional use of the parallel port. For example, you can purchase network adapters, high-capacity floppy disk drives, CD-ROM drives, scanners, and tape backup units that attach to the parallel port.

The tasks traditionally performed by both serial and parallel ports are increasingly being performed by newer port types, such as USB and IEEE-1394, but, for some time to come, both legacy and newer port types will both be important I/O interface types.

Serial Ports

The asynchronous serial interface was designed as a system-to-system communications port. *Asynchronous* means that no synchronization or clocking signal is present, so characters can be sent with any arbitrary time spacing.

Each character that is sent over a serial connection is framed by a standard start-and-stop signal. A single 0 bit, called the *start bit*, precedes each character to tell the receiving system that the next eight bits constitute a byte of data. One or two stop bits follow the character to signal that the character has been sent. At the receiving end of the communication, characters are recognized by the start-and-stop signals instead of by the timing of their arrival. The asynchronous interface is character oriented and has an approximate 20% overhead for the extra information that is needed to identify each character.

Serial refers to data that is sent over a single wire, with each bit lining up in a series as the bits are sent. This type of communication is used over the phone system because it provides one wire for data in each direction.

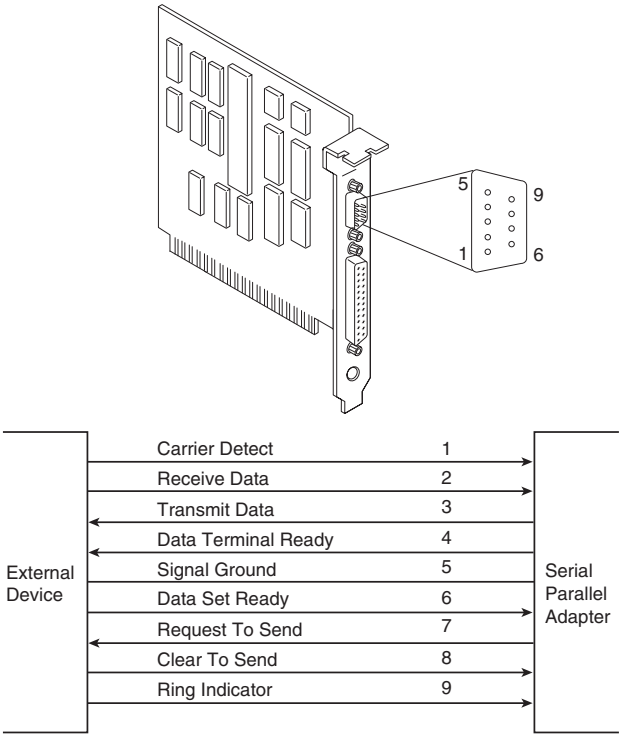
Typical Locations for Serial Ports

Typical systems include one or two serial ports, with connectors typically located at the rear of the system. Some recent consumer-oriented computers label a front-mounted serial port the "digital

camera port." This name comes from the use of serial ports for data transfer from low-end digital cameras. These built-in serial ports are controlled by either a Super I/O chip on the motherboard or a highly integrated South Bridge chip in the latest motherboard designs.

If you need more serial ports than your system has as standard, you can purchase single- or multi-port serial port cards or so-called *multi-I/O* cards that feature one or two serial ports and one or two parallel ports. Older systems based on the ISA or VL-Bus standard often have the serial ports attached to a multifunction card that also has IDE hard disk and floppy disk interfaces.

Note that card-based modems also incorporate a built-in serial port on the card as part of the modem circuitry. Figure 17.8 shows the standard 9-pin connector used with most modern external serial ports. Figure 17.9 shows the original standard 25-pin version.



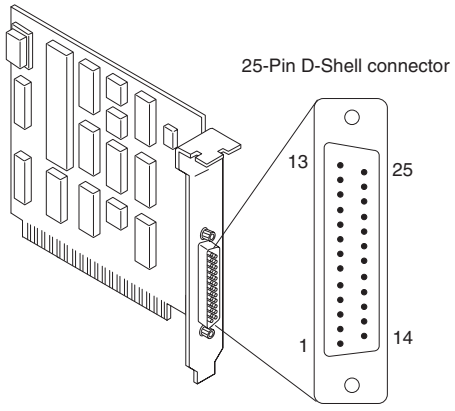


Figure 17.8 AT-style 9-pin serial-port connector specifications.

Serial ports can connect to a variety of devices, such as modems, plotters, printers, other computers, bar code readers, scales, and device control circuits.

The official specification recommends a maximum cable length of 50 feet. The limiting factor is the total load capacitance of cable and input circuits of the interface. The maximum capacitance is specified as 2500pF (picofarads). Special low-capacitance cables can effectively increase the maximum cable length greatly, to as much as 500 feet or more. Also available are line drivers (amplifier/repeaters) that can extend cable length even further.

	Description	Pin

9	22	RI	Ring indicator

Note

Macintosh systems use a similar serial interface, defined as RS-422. Most external modems in use today can interface with either RS-232 or RS-422, but it is safest to make sure that the external modem you get for your PC is designed for a PC, not a Macintosh.

UARTs

The heart of any serial port is the Universal Asynchronous Receiver/Transmitter (UART) chip. This chip completely controls the process of breaking the native parallel data within the PC into serial format and later converting serial data back into the parallel format.

Several types of UART chips have been available on the market. The original PC and XT used the 8250 UART, which was used for many years in low-priced serial cards. Starting with the first 16-bit systems, the 16450 UART typically was used. The only difference between these chips is their suitability for high-speed communications. The 16450 is better suited for high-speed communications than is the 8250; otherwise, both chips appear identical to most software. The 16550 UART was the first serial chip used in the IBM PS/2 line. Other 386 and higher systems rapidly adopted it. The 16550 functioned as the earlier 16450 and 8250 chips, but it also included a 16-byte buffer that aided in faster communications. This is sometimes referred to as a *FIFO (first in first out)* buffer. Unfortunately, the early 16550 chips had a few bugs, particularly in the buffer area. These bugs were corrected with the release of the 16550A. The most current version of the chip is the 16550D, which was released in 1995 and is produced by National Semiconductor.

Even though virtually all Pentium-class and newer systems have 16550-equivalent UART functionality in their serial ports, any search for a socketed 16550 chip on most of these systems would be done in vain. Instead, the functionality of the 16550, parallel port, and other ports is included as part of the Super I/O chip or, on the newest systems, the South Bridge chip.

Tip

The high-speed buffered 16550A (or newer) UART chip is pin for pin compatible with the 16450 UART. If your 16450 UART is socketed, a cheap and easy way to improve serial performance is to install a 16550 UART chip in the socket.

Because the 16550 is a faster, more reliable chip than its predecessors, it is best to ensure that your serial ports have either that chip or an equivalent. If you are in doubt about which type of UART you have in your system, you can use the Microsoft MSD program (provided with MS-DOS 6.x and Windows 9x/Me/2000) to determine the type of UART you have. Note that MSD often reports a 16450 UART as an 8250.

Note

Another way to tell whether you have a 16650 UART in Windows is to click the Start menu and then select Settings, Control Panel. Next, double-click Modems, and then click the Diagnostics tab. The Diagnostics tab shows a list of all COM ports in the system, even if they don't have a modem attached to them. Select the port you want to check in the list and click More Info. Windows communicates with the port to determine the UART type, and that information is listed in the Port Information portion of the More Info box. If a modem is attached, additional information about the modem is displayed.

The original designer of these UARTs is National Semiconductor (NS). So many other manufacturers are producing clones of these UARTs that you probably don't have an actual NS brand part in your system. Even so, the part you have is compatible with one of the NS parts, hopefully the 16550. In other words, check to see that whatever UART chip you have does indeed feature the 16-byte FIFO buffer, as found in the NS 16550 part.

◀◀ See "Super I/O Chips," p. 290.

8250

IBM used this original chip in the PC serial port card. This chip had no transmit/receive buffer, so it was very slow. The chip also had several bugs, none of which were serious. The PC and XT ROM BIOSes were written to anticipate at least one of the bugs. The 8250B replaced this chip.

8250A

Do not use the second version of the 8250 in any system. This upgraded chip fixes several bugs in the 8250, including one in the interrupt enable register, but because the PC and XT ROM BIOSes expect the bug, this chip does not work properly with those systems. The 8250A works in an AT system that does not expect the bug, but it does not work adequately at 9600bps.

8250B

The last version of the 8250 fixes bugs from the previous two versions. The interrupt enable bug in the original 8250, which is expected by the PC and XT ROM BIOS software, has been put back into this chip, making the 8250B the most desirable chip for any non-AT serial port application. The 8250B chip might work in an AT under DOS, but it does not run properly at 9600bps because, like all 8250s, it has no transmit/receive buffer.

16450

IBM selected the higher-speed version of the 8250 for the AT. The higher performance comes mainly from a 1-byte transmit/receive buffer contained within the chip. Because this chip has fixed the aforementioned interrupt enable bug, the 16450 does not operate properly in many PC or XT systems because they expect this bug to be present. OS/2 requires this chip as a minimum; otherwise, the serial ports do not function properly. It also adds a scratch-pad register as the highest register. The 16450 is used primarily in AT systems because of its increase in throughput over the 8250B.

16550 Series

This chip is pin compatible with the 16450 but is much faster due to a built-in 16-character transmit/receive FIFO buffer. It also allows multiple DMA channel access. The original version of this chip did not allow the buffer to work, but all 16550A or later revisions have the bug fixed. The last version produced by National Semiconductor was called the 16550D. Use a version of this UART in

your serial port if you do any communications at 9600bps or higher. If your communications program uses the FIFO—and all of them do today—it can greatly increase communications speed and eliminate lost characters and data at the higher speeds. Virtually all Super I/O chips contain the equivalent of dual 16550A or later chips. Most 16550 UARTs have a maximum communications speed of 115Kbps.

16650, 16750, and 16850

Several companies have produced versions of the 16550 with larger buffers:

- The 16550 has a 32-byte buffer.
- The 16750 has a 64-byte buffer.
- The 16850 has a 128-byte buffer.

These chips are not from National Semiconductor, and the designations only imply that they are compatible with the 16550 but have a larger buffer. These larger-buffered versions allow speeds of 230Kbps (16650), 460Kbps (16750), and 920Kbps (16850) and are recommended when running a high-speed external communications link, such as an ISDN terminal adapter or external 56Kbps modem. These are discussed more in the following section.

High-Speed Serial Port Cards

If you are using external RS-232 devices designed to run at speeds higher than 115Kbps (the maximum speed of the 16550 series UARTs and equivalents), you can't achieve maximum performance unless you replace your existing serial ports with add-on cards using one of the 16550, 16650, or 16750 UARTs discussed earlier. Most cards allow raw port speed settings of 230Kbps, 460Kbps, or even higher, which is valuable when connecting a PC to a high-speed external component that is connected to a serial port, such as an ISDN terminal adapter. You can't really get the full-speed benefit of an external ISDN modem (terminal adapter) unless your serial port can go at least 230Kbps. Lava Computer Mfg. and SIIG are two of the companies that offer a complete line of high-speed serial and parallel port cards (see the Vendor List on the accompanying DVD).

Onboard Serial Ports

Starting with late-model 486-based systems in the mid-1990s, a component on the motherboard called a *Super I/O* chip began to replace separate UART chips. This usually has two serial port UARTs as well as a multimode parallel port, floppy controller, keyboard controller, and sometimes the CMOS memory—all built into a single tiny chip. Still, this chip acts as if all these separate devices were installed: That is, from a software point of view, both the operating system and applications still act as if separate UART chips were installed on serial port adapter cards. The most recent systems integrate the functions of a Super I/O chip into the South Bridge chip. As with the Super I/O chip, South Bridge chips with integrated I/O are transparent to software. Super I/O and South Bridge chips are discussed throughout this chapter and in Chapter 4, "Motherboards and Buses."

Serial Port Configuration

Each time a character is received by a serial port, it has to get the attention of the computer by raising an interrupt request line (IRQ). Eight-bit ISA bus systems have eight of these lines, and systems with a 16-bit ISA bus have 16 lines. The 8259 interrupt controller chip or equivalent typically handles these requests for attention. In a standard configuration, COM1 uses IRQ4, and COM 2 uses IRQ3. Even on the latest systems, the default COM port assignments remain the same for compatibility with older software and hardware.

When a serial port is installed in a system, it must be configured to use specific I/O addresses (called ports) and interrupts (called IRQs). The best plan is to follow the existing standards for how these devices are to be set up. For configuring serial ports, use the addresses and interrupts indicated in Table 17.10.

Table 17.10 Standard Serial I/O Port Addresses and Interrupts

COM x	I/O Ports	IRQ
COM1	3F8–3FFh	IRQ[4]
COM 2	2F8–2FFh	IRQ[3]
COM 3	3E8–3EFh	IRQ4[1]
COM 4	2E8–2EFh	IRQ3[1]

1. Note that although many serial ports can be set up to share IRQ 3 and IRQ 4 with COM1 and COM 2, it is not recommended. The best recommendation is setting COM 3 to IRQ 10 and COM4 to IRQ 11 (if available). If ports above COM 3 are required, it is recommended that you purchase a special multiport serial board, preferably a PCI-based board that supports IRQ sharing without conflicts.

Be sure that, if you are adding more than the standard COM1 and COM2 serial ports, they use unique and nonconflicting interrupts. If you purchase a serial port adapter card and intend to use it to supply ports beyond the standard COM1 and COM2, be sure it can use interrupts other than IRQ3 and IRQ4; the latest PCI-based serial port boards take advantage of IRQ sharing features to allow COM3 and above to use a single IRQ without conflicts.

Note that BIOS manufacturers never built support for COM3 and COM4 into the BIOS. Therefore, DOS can't work with serial ports above COM2 because DOS gets its I/O information from the BIOS. The BIOS finds out what is installed in your system, and where it is installed, during the power on self test (POST). The POST checks only for the first two installed ports. This is not a problem under Windows because Windows 95 and later have built-in support for up to 128 ports.

With support for up to 128 serial ports in Windows, using multiport boards in the system is much easier. Multiport boards give your system the capability to collect or share data with multiple devices while using only one slot and one interrupt.

Caution

Sharing interrupts between COM ports—or any devices—can function properly sometimes and not others. It is recommended that you never share interrupts between multiple ISA-based serial ports, such as the COM ports built into your motherboard or found on an ISA modem. Trying to track down drivers, patches, and updates to allow this to work successfully—if it's even possible in your system—can cause you hours of frustration.

◀◀ See "Resolving Resource Conflicts," p. 337.

Testing Serial Ports

You can perform several tests on serial and parallel ports. The two most common types of tests are those that involve software only and those that involve both hardware and software. The software-only tests are done with diagnostic programs, such as Microsoft's MSD or the Modem diagnostics built into Windows, whereas the hardware and software tests involve using a wrap plug to perform loopback testing.

▶▶ See "Testing Parallel Ports," p. 993.

▶▶ See "Advanced Diagnostics Using Loopback Testing," p. 984.

Microsoft Diagnostics

Microsoft Diagnostics (MSD) is a diagnostic program supplied with MS-DOS 6.x, Windows 3.x, and Windows 9x/Me/2000. In Windows 95 this program can be found on the CD-ROM in the `\other\msd` directory, and in Windows 98/Me/2000, you can find it on the CD-ROM in the `\tools\oldmsdos` directory. MSD is not automatically installed when you install the operating system. To use it, you must run it from the CD-ROM directly or copy the program from the CD-ROM to your hard disk.

For the most accurate results, many diagnostics programs, such as MSD, are best run in a DOS-only environment. Because of this, you need to restart the machine in DOS mode before using them. Then, to use MSD, switch to the directory in which it is located. This is not necessary, of course, if the directory that contains the program is in your search path—which is often the case with the DOS 6.x or Windows-provided versions of MSD. Then, simply type **`MSD`** at the DOS prompt and press Enter. Soon you see the MSD screen.

Select the Serial Ports option. Notice that you are given information about which type of serial chip you have in your system, as well as information about which ports are available. If any of the ports are in use (with a mouse, for example), that information is provided as well.

MSD is helpful in at least determining whether your serial ports are responding. If MSD can't determine the existence of a port, it does not provide the report that indicates that the port exists. This sort of "look-and-see" test is the first action I usually take to determine why a port is not responding.

Troubleshooting Ports in Windows

Windows 9x/Me can tell you whether your ports are functioning. First, you must verify that the required communications files are present to support the serial ports in your system:

1. Verify the file sizes and dates of both `COMM.DRV` (16-bit serial driver) and `SERIAL.VXD` (32-bit serial driver) in the `SYSTEM` directory, compared to the original versions of these files from the Windows 9x/Me CD-ROM.
2. Confirm that the following lines are present in `SYSTEM.INI`:

```
[boot]
comm.drv=comm.drv
[386enh]
device=*vcd
```

The `SERIAL.VXD` driver is not loaded in `SYSTEM.INI`; instead, it is loaded through the Registry.

Windows 2000 and XP use the `SERIAL.SYS` and `SERENUM.SYS` drivers for handling RS-232 devices. You can compare the file sizes and dates for these files to those on the Windows 2000 CD-ROM.

If both drivers are present and accounted for, you can determine whether a particular serial port's I/O address and IRQ settings are properly defined by following these steps for Windows 9x/Me/2000:

1. Right-click the My Computer icon on the desktop and select Properties, or double-click the System icon in the Control Panel. Click the Device Manager tab, click Ports, and then select a specific port (such as COM1).
2. Click the Properties button, and then click the Resources tab to display the current resource settings (IRQ, I/O) for that port.
3. Check the Conflicting Devices List to see whether the port is using resources that conflict with other devices. If the port is in conflict with other devices, click the Change Setting button, and then select a configuration that does not cause resource conflicts. You might need to experiment with these settings until you find the correct one.

4. If the resource settings can't be changed, most likely they must be changed via the BIOS Setup. Shut down and restart the system, enter the BIOS setup, and change the port configurations there.

◀◀ See "Resolving Resource Conflicts," p. 337.

A common problem with non-Plug and Play modems can occur when people try to use a modem on COM3 with a serial mouse or other device on COM1. Typically, COM1 and COM3 ports use the same IRQ, meaning that they can't be used simultaneously. The COM2 and COM4 ports have the same problem sharing IRQs. If possible, change the COM3 or COM4 port to an IRQ setting that is not in conflict with COM1 or COM2. Note also that some video adapters have an automatic address conflict with COM4.

Advanced Diagnostics Using Loopback Testing

One of the most useful types of diagnostic test is the loopback test, which can be used to ensure the correct function of the serial port and any attached cables. Loopback tests are basically internal (digital) or external (analog). You can run internal tests by simply unplugging any cables from the port and executing the test via a diagnostics program.

The external loopback test is more effective. This test requires that a special loopback connector or wrap plug be attached to the port in question. When the test is run, the port is used to send data out to the loopback plug, which simply routes the data back into the port's receive pins so the port is transmitting and receiving at the same time. A loopback or wrap plug is nothing more than a cable that is doubled back on itself. Most diagnostics programs that run this type of test include the loopback plug, and if not, these types of plugs easily can be purchased or even built.

Following is a list of the wiring necessary to construct your own serial port loopback or wrap plugs:

- *Standard IBM-type 25-pin serial (female DB25S) loopback connector (wrap plug).* Connect the following pins:

  1 to 7

  2 to 3

  4 to 5 to 8

  6 to 11 to 20 to 22

  15 to 17 to 23

  18 to 25

- *Norton Utilities (Symantec) 25-pin serial (female DB25S) loopback connector (wrap plug).* Connect the following pins:

  2 to 3

  4 to 5

  6 to 8 to 20 to 22

- *Standard IBM-type 9-pin serial (female DB9S) loopback connector (wrap plug).* Connect the following pins:

  1 to 7 to 8

  2 to 3

  4 to 6 to 9

- *Norton Utilities (Symantec) 9-pin serial (female DB9S) loopback connector (wrap plug).* Connect the following pins:

  2 to 3

  7 to 8

  1 to 4 to 6 to 9

◀◀ See "Serial Ports," p. 975.

To make these loopback plugs, you need a connector shell with the required pins installed. Then, wire wrap or solder the wires, interconnecting the appropriate pins inside the connector shell as specified in the preceding list.

In most cases, purchasing a set of loopback connectors that are premade is less expensive than making them yourself. Most companies that sell diagnostics software can also sell you a set of loopback plugs. Some hardware diagnostic programs, such as Smith Micro's CheckIt Suite, include loopback plugs with the software.

One advantage of using loopback connectors is that you can plug them into the ends of a cable that is included in the test. This can verify that both the cable and the port are working properly.

If you need to test serial ports further, see Chapter 23, "PC Diagnostics, Testing, and Maintenance," which describes third-party testing software.

Parallel Ports

Parallel ports are normally used for connecting printers to a PC. Even though that was their sole original intention, parallel ports have become much more useful over the years as a more general-purpose, relatively high-speed interface between devices (when compared to serial ports). Today, USB 1.1-compliant ports are almost as fast as parallel ports, and IEEE-1394 ports are significantly faster. Originally, parallel ports were one way only; however, modern parallel ports can send and receive data when properly configured.

Parallel ports are so named because they have eight lines for sending all the bits that comprise 1 byte of data simultaneously across eight wires. This interface is fast and traditionally has been used for printers. However, programs that transfer data between systems always have used the parallel port as an option for transmitting data because it can do so 4 bits at a time, rather than 1 bit at a time as with a serial interface.

The following section looks at how these programs transfer data between parallel ports. The only problem with parallel ports is that their cables can't be extended for any great length without amplifying the signal; otherwise, errors occur in the data. Table 17.11 shows the pinout for a standard PC parallel port.

Table 17.11 25-Pin PC-Compatible Parallel Port Connector

Pin	Description	I/O	Pin	Description	I/O
1	-Strobe	Out	14	-Auto Feed	Out
2	+Data Bit 0	Out	15	-Error	In
3	+Data Bit 1	Out	16	-Initialize Printer	Out
4	+Data Bit 2	Out	17	-Select Input	Out
5	+Data Bit 3	Out	18	-Data Bit 0 Return (GND)	In
6	+Data Bit 4	Out	19	-Data Bit 1 Return (GND)	In
7	+Data Bit 5	Out	20	-Data Bit 2 Return (GND)	In
8	+Data Bit 6	Out	21	-Data Bit 3 Return (GND)	In
9	+Data Bit 7	Out	22	-Data Bit 4 Return (GND)	In
10	-Acknowledge	In	23	-Data Bit 5 Return (GND)	In
11	+Busy	In	24	-Data Bit 6 Return (GND)	In
12	+Paper End	In	25	-Data Bit 7 Return (GND)	In
13	+Select	In			

IEEE-1284 Parallel Port Standard

The IEEE-1284 standard, called Standard Signaling Method for a Bidirectional Parallel Peripheral Interface for Personal Computers, was approved for final release in March 1994. This standard defines the physical characteristics of the parallel port, including data-transfer modes and physical and electrical specifications. IEEE-1284 defines the electrical signaling behavior external to the PC for a multimodal parallel port that can support 4-bit modes of operation. Not all modes are required by the 1284 specification, and the standard makes some provision for additional modes.

The IEEE-1284 specification is targeted at standardizing the behavior between a PC and an attached device, specifically attached printers. However, the specification is also of interest to vendors of parallel port peripherals (removable-media drives, scanners, and so on).

IEEE-1284 pertains only to hardware and line control and does not define how software is to talk to the port. An offshoot of the original 1284 standard has been created to define the software interface. The IEEE-1284.3 committee was formed to develop a standard for software that is used with IEEE-1284-compliant hardware. This standard, designed to address the disparity among providers of parallel port chips, contains a specification for supporting EPP (the Enhanced Parallel Port) mode via the PC's system BIOS.

IEEE-1284 enables much higher throughput in a connection between a computer and a printer or two computers. The result is that the printer cable is no longer the standard printer cable. The IEEE-1284 printer cable uses twisted-pair technology, which results in a much more reliable and error-free connection.

The IEEE-1284 standard also defines the parallel port connectors, including the two preexisting types (called Type A and Type B), as well as an additional high-density Type C connector. Type A refers to the standard DB25 connector used on most PC systems for parallel port connections, whereas Type B refers to the standard 36-pin Centronics-style connector found on most printers. Type C is a new high-density 36-pin connector that can be found on some of the newer printers on the market, such as those from HP. The three connectors are shown in Figure 17.10.

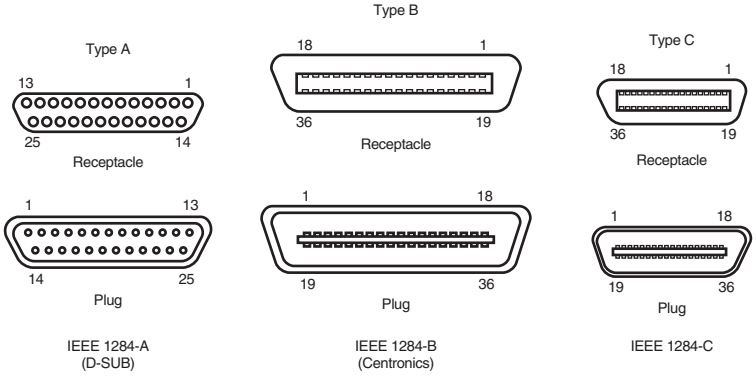

Figure 17.10 The three different types of IEEE-1284 parallel port connectors.

The IEEE-1284 parallel port standard defines five port-operating modes, emphasizing the higher-speed EPP and ECP modes. Some of the modes are input only, whereas others are output only. These five modes combine to create four types of ports, as shown in Table 17.12.

Table 17.12 Types of IEEE-1284 Ports

Parallel Port Type	Input Mode	Output Mode	Comments
SPP (Standard Parallel Port)	Nibble	Compatible	4-bit input, 8-bit output
Bidirectional	Byte	Compatible	8-bit I/O
EPP (Enhanced Parallel Port)	EPP	EPP	8-bit I/O
ECP (Enhanced Capabilities Port)	ECP	ECP	8-bit I/O, uses DMA

The 1284-defined parallel port modes are shown in Table 17.13, which also shows the approximate transfer speeds.

Table 17.13 IEEE-1284 Parallel Port Modes

Parallel Port Mode	Direction	Transfer Rate
Nibble (4-bit)	Input only	50KB/sec
Byte (8-bit)	Input only	150KB/sec
Compatible	Output only	150KB/sec
EPP (Enhanced Parallel Port)	Input/Output	500KB–2MB/sec
ECP (Enhanced Capabilities Port)	Input/Output	500KB–2MB/sec

Each of the port types and modes is discussed in the following sections.

Standard Parallel Ports

Older PCs did not have different types of parallel ports available. The only available port was the parallel port that was used to send information from the computer to a device such as a printer. The unidirectional nature of the original PC parallel port is consistent with its primary use—that is, sending data to a printer. There were times, however, when it was desirable to have a bidirectional port—for

example, when it was necessary to receive feedback from a printer, which was common with PostScript printers. This could not be done easily with the original unidirectional ports.

Although it was never intended to be used for input, a clever scheme was devised in which four of the signal lines can be used as a 4-bit input connection. Thus, these ports can do 8-bit (byte) output (called compatible mode) and 4-bit input (called nibble mode). This is still very common on low-end desktop systems. Systems built after 1993 are likely to have more capable parallel ports, such as bidirectional, EPP, or ECP.

Standard parallel ports are capable of effective transfer rates of about 150KB/sec output and about 50KB/sec input.

Bidirectional (8-bit) Parallel Ports

With the introduction of the PS/2 series of machines in 1987, IBM introduced the bidirectional parallel port. These are commonly found in PC-compatible systems today and can be designated "bidirectional," "PS/2 type," or "extended" parallel ports. This port design opened the way for true communication between the computer and the peripheral across the parallel port. This was done by defining a few of the previously unused pins in the parallel connector, and by defining a status bit to indicate in which direction information was traveling across the channel. This allowed for a true 8-bit (called byte mode) input.

These ports can do both 8-bit input and output using the standard eight data lines and are considerably faster than the 4-bit ports when used with external devices. Bidirectional ports are capable of approximately 150KB/sec transfer rates on both output and input. Some newer systems use this as their "standard" mode.

Enhanced Parallel Port

EPP is a newer specification, sometimes referred to as the Fast Mode parallel port. Intel, Xircom, and Zenith Data Systems developed and announced the EPP in October 1991. The first products to offer EPP were Zenith Data Systems laptops, Xircom Pocket LAN adapters, and the Intel 82360 SL I/O chip. Currently, almost all systems include a multimode parallel port that supports EPP mode; it's usually built into the Super I/O chip on the motherboard.

EPP operates at almost ISA bus speed and offers a tenfold increase in the raw throughput capability over a conventional parallel port. EPP is especially designed for parallel port peripherals, such as LAN adapters, disk drives, and tape backups. EPP has been included in the new IEEE-1284 Parallel Port standard. Transfer rates of up to 2MBps are possible with EPP.

Since the original Intel 82360 SL I/O chip in 1992, other major chip vendors (such as National Semiconductor, SMC, Western Digital, and VLSI) have also produced I/O chipsets that offer some form of EPP capability. One problem is that the procedure for enabling EPP across the various chips differs widely from vendor to vendor, and many vendors offer more than one I/O chip.

EPP version 1.7 (March 1992) identifies the first popular version of the hardware specification. With minor changes, this has since been abandoned and folded into the IEEE-1284 standard. Some technical reference materials have erroneously made reference to "EPP specification version 1.9," causing confusion about the EPP standard. Note that "EPP version 1.9" technically does not exist, and any EPP specification after the original version 1.7 is more accurately referred to as a part of the IEEE-1284 specification.

Unfortunately, this has resulted in two somewhat incompatible standards for EPP parallel ports: the original EPP Standards Committee version 1.7 standard and the IEEE-1284 Committee standard, usually called EPP version 1.9. The two standards are similar enough that new peripherals can be

designed to support both, but older EPP 1.7 peripherals might not operate with EPP 1284 (EPP 1.9) ports. For this reason, many multimode ports allow configuration in either EPP 1.7 or 1.9 mode, normally selected via the BIOS Setup.

EPP ports are now supported in virtually all Super I/O chips that are used on modern motherboards and in South Bridge chips that integrate I/O functions. Because the EPP port is defined in the IEEE-1284 standard, it also has gained software and driver support, including support in Windows NT.

Enhanced Capabilities Port

AIn 1992, Microsoft and Hewlett-Packard announced another type of high-speed parallel port is the Enhanced Capabilities Port (ECP). Similar to EPP, ECP offers improved performance for the parallel port and requires special hardware logic.

Since the original announcement, ECP is included in IEEE-1284—just like EPP. Unlike EPP, however, ECP is not tailored to support portable PCs' parallel port peripherals; its purpose is to support an inexpensive attachment to a very high-performance printer or scanner. Furthermore, ECP mode requires the use of a DMA channel, which EPP did not define and which can cause troublesome conflicts with other devices that use DMA. Most PCs with newer Super I/O chips can support either EPP or ECP mode.

Most new systems are being delivered with ECP ports that support high throughput communications. In most cases, the ECP ports can be turned into EPP or standard parallel ports via BIOS. However, it's recommended that the port be placed in ECP mode for the best throughput.

Depending on the motherboard, the DMA channel assignment used for ECP mode on a built-in parallel might be performed through the BIOS setup program or through moving a jumper block on the motherboard itself.

Upgrading to EPP/ECP Parallel Ports

Virtually every new or recent system today supports both the EPP and ECP modes of the IEEE 1284 parallel port standard. However, if you are working with an older system that might not have these capabilities built into the BIOS or are dealing with an add-on parallel port card, you might not know which modes the port can support.If you want to test the parallel ports in a system, especially to determine which type they are, I highly recommend a utility called Parallel. This is a handy parallel port information utility that examines your system's parallel ports and reports the port type, I/O address, IRQ level, BIOS name, and an assortment of informative notes and warnings in a compact and easy-to-read display. The output can be redirected to a file for tech support purposes. Parallel uses very sophisticated techniques for port and IRQ detection, and it is aware of a broad range of quirky port features. You can get it from Parallel Technologies (see the Vendor List on the DVD-ROM).

If you have an older system that does not include an EPP/ECP port and you want to upgrade, several companies now offer boards with the correct Super I/O chips to implement these features. I recommend that you check with Parallel Technologies, Byterunner Technologies, Lava Computer Mfg., or SIIG; they are listed in the Vendor List on the DVD accompanying this book.

High-speed parallel ports such as EPP and ECP often are used for supporting external peripherals, such as Zip drives, CD-ROM drives, scanners, tape drives, and even hard disks. Most of these devices attach to the parallel port using a pass-through connection. This means your local printer can still work through the port, along with the device. The device will have its own drivers that mediate both the communications with the device and the printer pass-through. Using EPP or ECP mode, communications speeds that are as high as 2MBps can be achieved. This can enable a relatively high-speed device to function almost as if it were connected to the system bus internally.

Parallel Port Configuration

The configuration of parallel ports is not as complicated as it is for serial ports. Even the original IBM PC had BIOS support for three LPT ports. Table 17.14 shows the standard I/O address and interrupt settings for parallel port use.

Table 17.14 Parallel Interface I/O Port Addresses and Interrupts

Standard LPTx	Alternate LPTx	I/O Ports	IRQ
LPT1	—	3BC–3BFh	IRQ7
LPT1	LPT2	378–37Ah	IRQ5
LPT2	LPT3	278h–27Ah	IRQ5

Because the BIOS and DOS have always provided three definitions for parallel ports, problems with older systems are infrequent. Problems can arise, however, from the lack of available interrupt-driven ports for ISA/PCI bus systems. Usually, an interrupt-driven port is not absolutely required for printing operations; in fact, many programs do not use the interrupt-driven capability. However, some programs do use the interrupt, such as network print programs and other types of background or spooler-type printer programs.

Also, high-speed laser-printer utility programs often use the interrupt capabilities to enable printing. If you use these types of applications on a port that is not interrupt driven, you see the printing slow to a crawl—if it works at all. The only solution is to use an interrupt-driven port. MS-DOS and Windows 9x/Me/2000 now support up to 128 parallel ports.

To configure parallel ports in ISA/PCI bus systems, you normally use the BIOS Setup program for ports that are built into the motherboard, or you might need to set jumpers and switches or use a setup program for adapter-card-based ports. Because each board on the market is different, you always should consult the OEM manual for that particular card if you need to know how the card should be configured.

◀◀ See "BIOS Hardware/Software," p. 357.

Linking Systems with Serial or Parallel Ports

You can connect two systems locally using their serial or parallel ports along with specially wired cables. This form of connection has been used over the years to enable a quick and easy mini-LAN to be set up that allows for the transfer of data between two systems. This can be especially useful when you are migrating your data to a new system you have built or purchased.

Even though using serial or parallel ports to connect two systems to migrate data can be useful, a much better way to connect two systems is to use Ethernet cards and what is commonly called a *crossover* cable. Using this type of connection, you can establish a LAN connection between the two systems and transfer data at the full speed of the Ethernet network, which is 10Mbps, 100Mbps, or 1,000Mbps (1.25MBps, 12.5MBps, or 125MBps). Using serial or parallel ports to transfer data between two systems was more prevalent when most systems did not include some form of network interface card (NIC).

Several free and commercial programs can support serial or parallel-port file transfers. MS-DOS 6.0 and later include a program called Interlink, whereas Windows 95 and later include software called either Direct Cable Connection or Direct Parallel Connection. Other commercially available software includes Laplink.com's LapLink, SmithMicro's CheckIt Fast Move, and Symantec's PC Anywhere, among others.

Serial Port Transfers

Serial ports have always been used for communications between systems, but the ports were usually connected to modems that convert the data to be transmitted over telephone lines, enabling long-distance connections. If the systems were in the same room, you could connect the serial ports directly without using modems by instead using what is commonly referred to as a *null modem cable*. The name comes from the fact that there really aren't any modems present—the cable effectively replaces the modems that would be used at either end. The only drawback is that, because serial ports evolved to support relatively low-speed modem communications, even when using a null modem cable, the connection would be slow because most ports can transmit at 115.2Kbps (14.4KBps).

By using a null modem cable, serial ports can be used to transfer data between systems, although the performance is much lower than when using parallel ports. A serial null modem cable has either a 9-pin or a 25-pin female connector on both ends. The cable should be wired as shown in Table 17.15.

Table 17.15 Serial Null Modem Cable Wiring (9-Pin or 25-Pin Connectors)

9-Pin	25-Pin	Signal	<-to->	Signal	25-Pin	9-Pin
Pin 5	Pin 7	Ground	<->	Ground	Pin 7	Pin 5
Pin 3	Pin 2	Transmit	<->	Receive	Pin 3	Pin 2
Pin 7	Pin 4	RTS	<->	CTS	Pin 5	Pin 8
Pin 6	Pin 6	DSR	<->	DTR	Pin 20	Pin 4
Pin 2	Pin 3	Receive	<->	Transmit	Pin 2	Pin 3
Pin 8	Pin 5	CTS	<->	RTS	Pin 4	Pin 7
Pin 4	Pin 20	DTR	<->	DSR	Pin 6	Pin 6

If both systems feature infrared serial ports, you can connect the two systems via an infrared connection that uses no cable at all. This type of connection is subject to the limitations of the infrared ports, which allow only very short (a few feet at most) distances with fairly slow data rates.

Because they work so slowly, I usually recommend using serial ports to transfer data between two systems only as a last resort. If possible, you should try to use either Ethernet cards and a crossover cable or parallel ports with an interlink cable for faster connections.

Parallel Port Transfers

Although the original intention for the parallel port was for it to be used to connect a printer, later implementations allowed for bidirectional data transfer. Bidirectional parallel ports can be used to quickly and easily transfer data between one system and another. If both systems use an EPP/ECP port, you can actually communicate at rates of up to 2MBps, which is far faster than the speeds achievable with serial port or infrared (IR) data transfers.

Connecting computers with parallel ports requires a special cable known as a *Direct Cable Connection (DCC)*, *interlink*, *laplink*, *parallel crossover*, or *parallel null modem* cable. Many of the commercial file transfer programs provide these cables with their software, or you can purchase them separately from most computer stores or companies that sell cables. However, if you need to make one for yourself, Table 17.16 provides the wiring diagram you need.

Table 17.16 Direct Cable Connection, Interlink, Laplink, or Parallel Null Modem Cable Wiring (25-Pin Connectors)

25-Pin Description	Signal	<-to-> Description	Signal	25-Pin
Pin 2	Data Bit 0	<->	-Error	Pin 15
Pin 3	Data Bit 1	<->	Select	Pin 13
Pin 4	Data Bit 2	<->	Paper End	Pin 12
Pin 5	Data Bit 3	<->	-Acknowledge	Pin 10
Pin 6	Data Bit 4	<->	Busy	Pin 11
Pin 15	-Error	<->	Data Bit 0	Pin 2
Pin 13	Select	<->	Data Bit 1	Pin 3
Pin 12	Paper End	<->	Data Bit 2	Pin 4
Pin 10	-Acknowledge	<->	Data Bit 3	Pin 5
Pin 11	Busy	<->	Data Bit 4	Pin 6
Pin 25	Ground	<->	Ground	Pin 25

Tip

Even though cables usually are provided for data-transfer programs, notebook users might want to look for an adapter that makes the appropriate changes to a standard parallel printer cable. This can make traveling lighter by preventing the need for additional cables.

Although the prebuilt parallel cables referred to in the previous tip work for connecting two machines with ECP/EPP ports, they can't take advantage of the advanced transfer rates of these ports. Special cables are needed to communicate between ECP/EPP ports. Parallel Technologies is a company that sells ECP/EPP cables for connecting to other ECP/EPP computers, as well as a universal cable for connecting any two parallel ports to use the highest speed.

Windows 95 and later versions include a special program called Direct Cable Connection or Direct Parallel Connection, which enables two systems to be networked together via a parallel transfer cable. Consult the Windows documentation for information on how to establish a DCC/Direct Parallel connection. Parallel Technologies has been contracted by Microsoft to supply the special DCC cables used to connect the systems, including a special type of cable that uses active electronics to ensure a reliable high-speed interconnection.

Parallel-to-SCSI Converters

Parallel ports can also be used to connect SCSI peripherals to a PC. With a parallel-to-SCSI converter, you can connect any type of SCSI device—such as hard disks, CD-ROM drives, tape drives, Zip drives, or scanners—to your PC, all via the parallel port. To connect to a SCSI device and also continue to be able to print, most parallel-to-SCSI converters include a pass-through connection for a printer.

Therefore, at one end of the converter is a connection to your parallel port, and at the other end is both SCSI and parallel-port connections. Thus, you can plug in a single SCSI device and still connect your printer as well. The drivers for the parallel-to-SCSI converter automatically pass through any information to the printer, so the printer works normally.

Adaptec is the major supplier of such converters, but they are available from other companies as well. Note that these converters are designed to handle a single SCSI device; you should buy a SCSI host adapter if you need to support two or more devices. Also note that even an EPP/ECP parallel port runs at only a fraction of the speed (2MBps) of even the slowest SCSI device (10MBps and up).

Testing Parallel Ports

Testing parallel ports is, in most cases, simpler than testing serial ports. The procedures are effectively the same as those used for serial ports, except that when you use the diagnostics software, you (obviously) select choices for parallel ports rather than serial ports.

Even though the software tests are similar, the hardware tests require the proper plugs for the loopback tests on the parallel port. Several loopback plugs are required, depending on what software you are using. Most use the IBM-style loopback, but some use the style that originated in the Norton Utilities diagnostics.

You can purchase loopback plugs or build them yourself. The following wiring is needed to construct your own parallel loopback or wrap plugs to test a parallel port:

- *IBM 25-pin parallel (male DB25P) loopback connector (wrap plug).* Connect the following pins:

  1 to 13

  2 to 15

  10 to 16

  11 to 17

- *Norton Utilities 25-pin parallel (male DB25P) loopback connector (wrap plug).* Connect the following pins:

  2 to 15

  3 to 13

  4 to 12

  5 to 10

  6 to 11

CHAPTER 18

Input Devices

Keyboards

One of the most basic system components is the keyboard, which is the primary input device. It is used for entering commands and data into the system. This section looks at the keyboards available for PC-compatible systems, examining the various types of keyboards, how the keyboard functions, the keyboard-to-system interface, and keyboard troubleshooting and repair.

In the years since the introduction of the original IBM PC, IBM has created three keyboard designs for PC systems, and Microsoft has augmented one of them. These designs have become de facto standards in the industry and are shared by virtually all PC manufacturers.

The primary keyboard types are as follows:

- 101-key Enhanced keyboard
- 104-key Windows keyboard
- 83-key PC and XT keyboard (obsolete)
- 84-key AT keyboard (obsolete)

This section discusses the 101-key Enhanced keyboard and the 104-key Windows keyboard, showing the layout and physical appearance of both. Although you can still find old systems that use the 83-key and 84-key designs, these are rare today. Because all new systems today use the 101- or 104-key keyboard design, these versions are covered here.

Note

If you need to learn more about the 83-key PC and XT keyboard or the 84-key AT keyboard, see Chapter 7 of *Upgrading and Repairing PCs, 10th Anniversary Edition*, on the DVD included with this book.

Enhanced 101-Key (or 102-Key) Keyboard

In 1986, IBM introduced the "corporate" Enhanced 101-key keyboard for the newer XT and AT models. I use the word "corporate" because this unit first appeared in IBM's RT PC, which was a RISC (reduced instruction set computer) system designed for scientific and engineering applications. Keyboards with this design were soon supplied with virtually every type of system and terminal IBM sold. Other companies quickly copied this design, which became the standard on Intel-based PC systems until the introduction of the 104-key Windows keyboard in 1995 (discussed later in this chapter).

The layout of this universal keyboard was improved over that of the 84-key unit, with perhaps the exception of the Enter key, which reverted to a smaller size. The 101-key Enhanced keyboard was designed to conform to international regulations and specifications for keyboards. In fact, other companies such as Digital Equipment Corporation (DEC) and Texas Instruments (TI) had already been using designs similar to the IBM 101-key unit. The IBM 101-key units originally came in versions with and without the status-indicator LEDs, depending on whether the unit was sold with an XT or AT system. Now many other variations are available from which to choose, including some with integrated pointing devices, such as the IBM TrackPoint II pointing stick, trackballs and touch pads, and programmable keys useful for automating routine tasks.

The Enhanced keyboard is available in several variations, but all are basically the same electrically and all can be interchanged. IBM—with its Lexmark keyboard and printer spinoff—and Unicomp (which now produces these keyboards) have produced a number of keyboard models, including versions with built-in pointing devices and new ergonomic layouts. With the replacement of the

Baby-AT motherboard and its five-pin DIN (an acronym for Deutsche Industrie Norm) keyboard connector by ATX motherboards, which use the six-pin mini-DIN keyboard connector, virtually all keyboards on the market today come with cables for the six-pin mini-DIN connector introduced on the IBM PS/2s.

Although the connectors might be physically different, the keyboards are not, and you can either interchange the cables or use a cable adapter to plug one type into the other; some keyboards you can buy at retail include the adapter in the package. See the section "Keyboard/Mouse Interface Connectors" and Figure 18.8 later in this chapter for the physical and electronic details of these connectors. Many keyboards now include both the standard mini-DIN as well as USB connectors for maximum flexibility when attaching to newer systems. See the section "USB Keyboards" later in this chapter for details on connecting keyboards via USB.

The 101-key keyboard layout can be divided into the following four sections:

- Typing area
- Numeric keypad
- Cursor and screen controls
- Function keys

The 101-key arrangement is similar to the Selectric keyboard layout, with the exception of the Enter key. The Tab, Caps Lock, Shift, and Backspace keys have a larger striking area and are located in the familiar Selectric locations. Ctrl and Alt keys are on each side of the spacebar, and the typing area and numeric keypad have home-row identifiers for touch typing.

The cursor- and screen-control keys have been separated from the numeric keypad, which is reserved for numeric input. (As with other PC keyboards, you can use the numeric keypad for cursor and screen control when the keyboard is not in Num Lock mode.) A division-sign key (/) and an additional Enter key have been added to the numeric keypad.

The cursor-control keys are arranged in the inverted T format that is now expected on all computer keyboards. The Insert, Delete, Home, End, Page Up, and Page Down keys, located above the dedicated cursor-control keys, are separate from the numeric keypad. The function keys, spaced in groups of four, are located across the top of the keyboard. The keyboard also has two additional function keys: F11 and F12. The Esc key is isolated in the upper-left corner of the keyboard. In addition, dedicated Print Screen/Sys Req, Scroll Lock, and Pause/Break keys are provided for commonly used functions.

Foreign-language versions of the Enhanced keyboard include 102 keys and a slightly different layout from the 101-key U.S. versions.

One of the many useful features of the IBM/Lexmark enhanced keyboard (now manufactured by Unicomp) is removable keycaps. This permits the replacement of broken keys and provides access for easier cleaning. Also, with clear keycaps and paper inserts, you can customize the keyboard. Keyboard templates are also available to provide specific operator instructions.

104-Key (Windows 9x/Me/2000/XP) Keyboard

With the introduction of Windows 95, a modified version of the standard 101-key design (created by Microsoft) appeared, called the 104-key Windows keyboard.

If you are a touch typist as I am, you probably really hate to take your hands off the keyboard to use a mouse. Windows 9x and newer versions make this even more of a problem because they use both the right and left mouse buttons (the right button is used to open shortcut menus). Many new keyboards, especially those in portable computers, include a variation of the IBM TrackPoint or the Cirque GlidePoint pointing devices (discussed later in this chapter), which enable touch typists to keep their

hands on the keyboard even while moving the pointer. However, another alternative is available that can help. When Microsoft released Windows 95, it also introduced the Microsoft Natural Keyboard, which implemented a revised keyboard specification that added three new Windows-specific keys to the keyboard.

The Microsoft Windows keyboard specification, which has since become a de facto industry standard for keyboard layouts, outlines a set of additional keys and key combinations. The 104-key layout includes left and right Windows keys and an Application key (see Figure 18.1). These keys are used for operating system and application-level keyboard combinations, similar to the existing Ctrl and Alt combinations. You don't need the new keys to use Windows, but software vendors are adding specific functions to their Windows products that use the new Application key (which provides the same functionality as clicking the right mouse button). The recommended Windows keyboard layout calls for the Left and Right Windows keys (called WIN keys) to flank the Alt keys on each side of the spacebar, as well as an Application key on the right of the Right Windows key. Note that the exact placement of these keys is up to the keyboard designer, so variations exist from keyboard to keyboard.

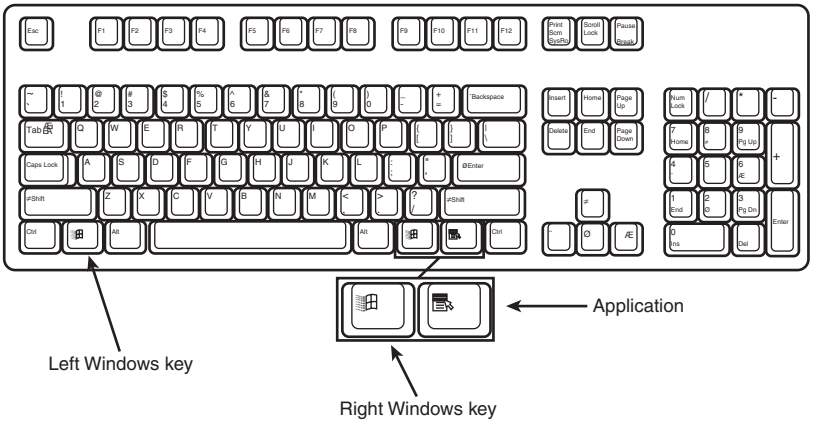

Figure 18.1 The 104-key Windows keyboard layout.

The WIN keys open the Windows Start menu, which you can then navigate with the cursor keys. The Application key simulates the right mouse button; in most applications, it brings up a context-sensitive pop-up menu. Several WIN key combinations offer preset macro commands as well. For example, you can press WIN+E to launch the Windows Explorer application. Table 18.1 shows a list of all the Windows key combinations used with the 104-key keyboard.

Table 18.1 Windows 9x/Me/2000/XP Key Combinations

Key Combination	Resulting Action
WIN+R	Runs dialog box
WIN+M	Minimize All
Shift+WIN+M	Undo Minimize All
WIN+D	Minimize All or Undo Minimize All
WIN+F1	Help

Table 18.1 Continued

Key Combination	Resulting Action
WIN+E	Starts Windows Explorer
WIN+F	Find Files or Folders
Ctrl+WIN+F	Find Computer
WIN+Tab	Cycles through taskbar buttons
WIN+Break	Displays System Properties dialog box
Application key	Displays a context menu for the selected item

The preceding keystroke combinations work with any manufacturer's 104-key keyboard, but users of certain Microsoft 104-key keyboards can enhance their keyboard use further by installing the IntelliType Pro software supplied by Microsoft with the keyboard.

The Windows keys are not mandatory when running Windows. In fact, preexisting standard key combinations perform the same functions as these newer keys. I also have noticed that only power users wanting to work as efficiently as possible by keeping their hands on the keyboard (and off the mouse) primarily use these combinations.

The Windows keyboard specification requires that keyboard makers increase the number of trilograms in their keyboard designs. A *trilogram* is a combination of three rapidly pressed keys that perform a special function, such as Ctrl+Alt+Delete. Designing a keyboard so that the switch matrix correctly registers the additional trilograms plus the additional Windows keys adds somewhat to the cost of these keyboards compared to the previous 101-key standard models.

Virtually all keyboard manufacturers have standardized on 104-key keyboards that include these Windows-specific keys. Some manufacturers have added browser control or other keys that, although not standard, can make them easier to use for navigating Web pages and launching various applications.

Running Windows Without a Mouse

Many people do not know they can dramatically enhance the use of Windows by using the keyboard as an adjunct to or even instead of the mouse for system control. Many keyboard shortcuts and other key commands are available that can greatly increase the speed and efficiency with which you operate Windows, especially if you are an accomplished touch typist. Because I use my PC mainly for writing, I find that taking my hand off the keyboard to use a mouse noticeably slows me down (which is one reason I use laptop systems or desktop keyboards with a more efficient TrackPoint pointing device). By augmenting Windows operations with the keyboard, you can control Windows more efficiently and accurately than with just a mouse.

In some cases, it is not only desirable but necessary to use the keyboard instead of a mouse, such as when your mouse is not functioning properly or is missing altogether. Because technicians often find themselves operating or testing equipment that is not fully functional, it is even more important for them to know how to operate Windows with the keyboard.

The following are the general keyboard-only commands for Windows 9x/Me/NT/2000/XP:

Key Combination	Resulting Action
F1	Starts Windows Help.
F10	Activates menu bar options.
Shift+F10	Opens a context menu (shortcut menu) for the selected item.
Ctrl+Esc	Opens the Start menu. You use the arrow keys to select an item.
Ctrl+Esc, Esc	Selects the Start button. Press Tab to select the taskbar, or press Shift+F10 for a context menu.
Alt+Tab	Switches to another running application. Hold down the Alt key and then press the Tab key to view the task-switching window.
Shift	Press down and hold the Shift key while you insert a CD-ROM to bypass the AutoPlay feature.
Alt+spacebar	Displays the main window's System menu. From the System menu, you can restore, move, resize, minimize, maximize, or close the window.
Alt+- (Alt+hyphen)	Displays the Multiple Document Interface (MDI) child window's System menu. From the MDI child window's System menu, you can restore, move, resize, minimize, maximize, or close the child window.
Ctrl+Tab	Switches to the next child window of an MDI application.
Alt+<underlined letter in menu>	Opens the corresponding menu.
Alt+F4	Closes the current window.
Ctrl+F4	Closes the current MDI window.
Alt+F6	Switches between multiple windows in the same program. For example, when Notepad's Find dialog box is displayed, Alt+F6 switches between the Find dialog box and the main Notepad window.

Here are the Windows dialog box keyboard commands:

Key Combination	Resulting Action
Tab	Moves to the next control in the dialog box.
Shift+Tab	Moves to the previous control in the dialog box.
Spacebar	If the current control is a button, this keyboard command clicks the button. If the current control is a check box, it toggles the check box. If the current control is an option button, it selects the option button.
Enter	Equivalent to clicking the selected button (the button with the outline).
Esc	Equivalent to clicking the Cancel button.
Alt+<underlined letter in dialog box item>	Moves to the corresponding item.
Ctrl+Tab/Ctrl+Shift+Tab	Moves through the property tabs.

These are the keyboard combinations for Windows Explorer tree controls:

Key Combination	Resulting Action
Numeric keypad *	Expands everything under the current selection.
Numeric keypad +	Expands the current selection.
Numeric keypad -	Collapses the current selection.

Key Combination	Resulting Action
Right arrow	Expands the current selection if it is not expanded. Otherwise, it goes to the first child.
Left arrow	Collapses the current selection if it is expanded; otherwise, it goes to the parent.

Here are the general Windows folder/shortcut controls:

Key Combination	Resulting Action
F4	Selects the Go To a Different Folder box and moves down the entries in the box (if the toolbar is active in Windows Explorer).
F5	Refreshes the current window.
F6	Moves among panes in Windows Explorer.
Ctrl+G	Opens the Go To Folder tool (in Windows 95 Windows Explorer only).
Ctrl+Z	Undoes the last command.
Ctrl+A	Selects all the items in the current window.
Backspace	Switches to the parent folder.
Shift+click	Selects the close button. (For folders, it closes the current folder plus all parent folders.)

These are the general folder and Windows Explorer shortcuts for a selected object:

Key Combination	Resulting Action
F2	Renames the object.
F3	Finds all files.
Ctrl+X	Cuts.
Ctrl+C	Copies.
Ctrl+V	Pastes.
Shift+Del	Deletes the selection immediately, without moving the item to the Recycle Bin.
Alt+Enter	Opens the property sheet for the selected object.
To copy a file	Press down and hold the Ctrl key while you drag the file to another folder.
To create a shortcut	Press down and hold Ctrl+Shift while you drag a file to the desktop or a folder.

USB Keyboards

The latest innovation in keyboard interfacing is connecting the keyboard to the PC via a USB port instead of the standard keyboard port. Because USB is a universal bus that uses a hub to enable multiple devices to connect to a single port, a single USB port in a system can replace the standard serial and parallel ports as well as the keyboard and mouse ports. Most current systems still include the standard ports (now called "legacy" ports) as well as USB, but some so-called "legacy-free" systems have only USB ports for interfacing all input/output devices.

Several keyboard manufacturers are marketing USB keyboards, including Microsoft with the Natural Keyboard Elite and Pro series keyboards. The Natural Keyboard Elite is unique among USB keyboards because it is designed to work with standard keyboard ports and also comes with an adapter that enables it to connect to the USB port on systems using Windows 98/Me/2000/XP. In addition, adapters are available from Logitech and others that can convert a USB port to a standard keyboard port if you want to use a non-USB-enabled keyboard on a newer legacy-free system.

Note

The internal electronics of this keyboard are different from other models, and the USB adapter included with the Natural Keyboard Elite will not work on other standard keyboards, such as the original Microsoft Natural Keyboard version 1.0.

Not all systems accept USB keyboards, even those with USB ports, because the standard PC BIOS has a keyboard driver that expects a standard keyboard port interface to be present. When a USB keyboard is installed, the system can't use it because no driver exists in the BIOS to make it work. In fact, some systems see the lack of a standard keyboard as an error and halt the boot process until one is installed.

To use a keyboard connected via the USB port, you must meet three requirements:

- Have a USB port in the system
- Run Microsoft Windows 98, Windows Me, Windows 2000, or Windows XP (all of which include USB keyboard drivers)
- Have a system chipset and BIOS that feature USB Legacy support

USB Legacy support means your motherboard has a chipset and ROM BIOS drivers that enable a USB keyboard to be used outside the Windows GUI environment. When a system has USB Legacy support enabled, a USB keyboard can be used with MS-DOS (for configuring the system BIOS) when using a command prompt within Windows or when installing Windows on the system for the first time. If USB Legacy support is not enabled on the system, a USB keyboard will function only when Windows is running.

Most recent systems include USB Legacy support, although it is disabled by default in the system BIOS.

Also, if the Windows installation fails and requires manipulation outside of Windows, the USB keyboard will not function unless it is supported by the chipset and the BIOS. Almost all 1998 and newer systems with USB ports include a chipset and BIOS with USB Legacy (meaning USB Keyboard) support.

Even though USB Legacy support enables you to use a USB keyboard in almost all situations, don't scrap your standard-port keyboards just yet. Some Windows-related bugs and glitches reported by users include the following:

- *Can't log on to Windows the first time after installing a USB keyboard.* The solution in some cases is to click Cancel when you are asked to log on and then allow the system to detect the keyboard and install drivers. The logon should work normally thereafter. In other cases, you might have to leave the keyboard unplugged when first booting and then plug it in after the OS desktop is up and running. This allows the keyboard to be detected and drivers loaded.
- *Some USB keyboards won't work when the Windows Emergency Boot Disk (EBD) is used to start the system.* The solution is to turn off the system, connect a standard keyboard, and restart the system.
- *Some users of Windows 98 and Windows 98 SE have reported conflicts between Windows and the BIOS when USB Legacy support is enabled on some systems.* This conflict can result in an incapability to detect the USB keyboard if you use the Windows 9x shutdown menu and choose to Restart the computer in MS-DOS mode. Check with the system or BIOS vendor for an updated BIOS or a patch to solve this conflict.

If you have problems with Legacy USB support, look at these possible solutions:

- Microsoft's Knowledge Base might address your specific combination of hardware.
- Your keyboard vendor might offer new drivers.
- Your system or motherboard vendor might have a BIOS upgrade you can install.

◀◀ See "Universal Serial Bus," p. 963.

Portable Keyboards

One of the biggest influences on keyboard design in recent years has been the proliferation of laptop and notebook systems. Because of size limitations, it is obviously impossible to use the standard keyboard layout for a portable computer. Manufacturers have come up with many solutions. Unfortunately, none of these solutions has become an industry standard, as the 101-key layout is. Because of the variations in design, and because a portable system keyboard is not as easily replaceable as that of a desktop system, the keyboard arrangement should be an important part of your purchasing decision.

Early laptop systems often used smaller-than-normal keys to minimize the size of the keyboard, which resulted in many complaints from users. Today, the keytops on portable systems are usually comparable in size to that of a desktop keyboard, although some systems include half-sized keytops for the function keys and other less frequently used keyboard elements. In addition, consumer demand has caused most manufacturers to retain the inverted-T design for the cursor keys after a few abortive attempts at changing their arrangement.

Of course, the most obvious difference in a portable system keyboard is the sacrifice of the numeric keypad. Most systems now embed the keypad into the standard alphabetical part of the keyboard, as shown in Figure 18.2. To switch the keys from their standard values to their keypad values, you typically must press a key combination involving a proprietary function key, often labeled Fn.

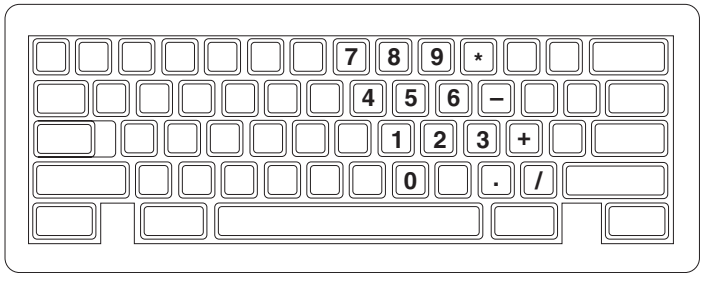

Figure 18.2 Most portable systems today embed the numeric keypad into an oddly shaped block of keys on the alphabetical part of the keyboard.

This is an extremely inconvenient solution, and many users abandon their use of the keypad entirely on portable systems. Unfortunately, some activities—such as the entry of ASCII codes using the Alt key—require the use of the keypad numbers, which can be quite frustrating on systems using this arrangement.

To alleviate this problem, many portable system manufacturers sell external numeric keypads that plug into the external keyboard port, a serial port, or a USB port. This is a great feature for somebody performing a lot of numeric data entry.

In addition to keypad control, the Fn key often is used to trigger other proprietary features in portable systems, such as toggling between an internal and external display and controlling screen brightness and sound volume.

Some portable system manufacturers have gone to great lengths to provide users with adequate keyboards. For a short time, IBM marketed systems with a keyboard that used a "butterfly" design. The keyboard was split into two halves that rested on top of one another when the system was closed. When you opened the lid, the two halves separated to rest side by side, forming a keyboard that was actually larger than the computer case.

Ironically, the trend toward larger-sized displays in portable systems has made this sort of arrangement unnecessary. Many manufacturers have increased the footprint of their notebook computers to accommodate 12" and even 15" display panels, leaving more than adequate room for a keyboard with full-size keys. However, even on the newest systems, there still isn't enough room for a separate numeric keypad.

◀◀ See "Keyboards," p. 996.

Num Lock

On IBM systems that support the Enhanced keyboard, when the system detects the keyboard on powerup, it enables the Num Lock feature and the light goes on. If the system detects an older 84-key AT-type keyboard, it does not enable the Num Lock function because these keyboards do not have cursor keys separate from the numeric keypad. When the Enhanced keyboards first appeared in 1986, many users (including me) were irritated to find that the numeric keypad was automatically enabled every time the system booted. Most system manufacturers subsequently began integrating a function into the BIOS setup that enabled you to specify the Num Lock status imposed during the boot process.

Some users thought that the automatic enabling of Num Lock was a function of the Enhanced keyboard because none of the earlier keyboards seemed to operate in this way. Remember that this function is not really a keyboard function but instead a function of the motherboard ROM BIOS, which identifies an Enhanced 101-key unit and turns on the Num Lock as a "favor." In systems with a BIOS that can't control the status of the numeric keypad, you can use the DOS 6.0 or higher version `NUMLOCK=` parameter in `CONFIG.SYS` to turn Num Lock on or off, as desired. Some versions of Windows appear to disable the Num Lock by default.

Keyboard Technology

The technology that makes up a typical PC keyboard is very interesting. This section focuses on all the aspects of keyboard technology and design, including the keyswitches, the interface between the keyboard and the system, the scan codes, and the keyboard connectors.

Keyswitch Design

Today's keyboards use any one of several switch types to create the action for each key. Most keyboards use a variation of the mechanical keyswitch. A mechanical keyswitch relies on a mechanical momentary contact-type switch to make the electrical contact that forms a circuit. Some high-end keyboards use a more sophisticated design that relies on capacitive switches. This section discusses these switches and the highlights of each design.

The most common type of keyswitch is the mechanical type, available in the following variations:

- Pure mechanical
- Foam element

- Rubber dome
- Membrane

Pure Mechanical Switches

The pure mechanical type is just that—a simple mechanical switch that features metal contacts in a momentary contact arrangement. The switch often includes a tactile feedback mechanism, consisting of a clip and spring arrangement designed to give a "clicky" feel to the keyboard and offer some resistance to the keypress (see Figure 18.3).

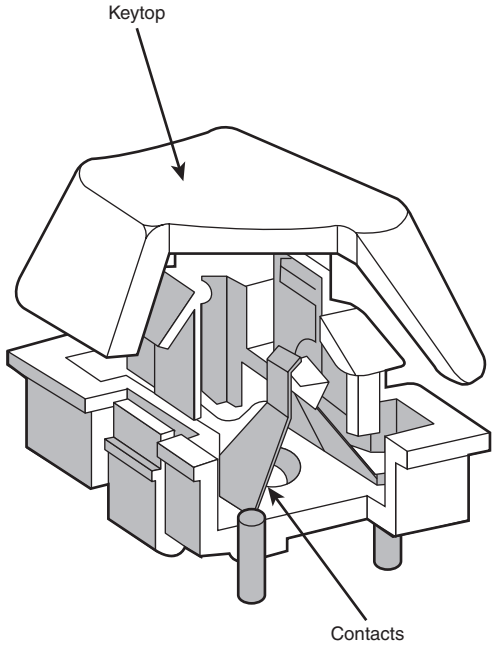

Figure 18.3 A typical mechanical switch used in NMB keyboards. As the key is pressed, the switch pushes down on the contacts to make the connection.

Mechanical switches are very durable, usually have self-cleaning contacts, and are normally rated for 20 million keystrokes (which is second only to the capacitive switch in longevity). They also offer excellent tactile feedback.

Despite the tactile feedback and durability provided by mechanical keyswitch keyboards, they have become much less popular than membrane keyboards (discussed later in this chapter), and many companies that produce keyboards that use mechanical keyswitches use them for only a few of their high-priced models. With the price of keyboards nosediving along with other traditional devices, such as mice and drives, the pressure on keyboard makers to cut costs has led many of them to abandon or de-emphasize mechanical-keyswitch designs in favor of the less expensive membrane keyswitch.

The Alps Electric mechanical keyswitch is used by many of the vendors who produce mechanical-switch keyboards, including Alps Electric itself. Other vendors who use mechanical keyswitches for some of their keyboard models include Adesso, Inc. (`www.adessoinc.com`), NMB Technologies (`www.nmbtech.com`), Chicony, Cherry (which uses its own 50-million-keystroke switches for its

G80-series keyboards; www.cherrycorp.com), Avant Prime and Stellar (revivals of the classic Northgate keyboards and available from Ergonomic Resources; www.ergo-2000.com), Kinesis (www.kinesis-ergo.com), SIIG (www.siig.com), and Focus (www.focustaipei.com). Many of these vendors sell through the OEM market, so you must look carefully at the detailed specifications for the keyboard to see whether it is a mechanical keyswitch model.

Foam Element Switches

Foam element mechanical switches were a very popular design in some older keyboards. Most of the older PC keyboards, including models made by Key Tronic and many others, used this technology. These switches are characterized by a foam element with an electrical contact on the bottom. This foam element is mounted on the bottom of a plunger that is attached to the key (see Figure 18.4).

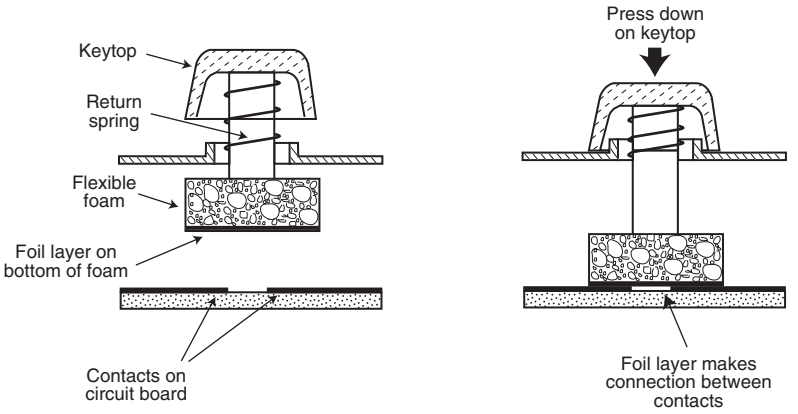

Figure 18.4 Typical foam element mechanical keyswitch.

When the switch is pressed, a foil conductor on the bottom of the foam element closes a circuit on the printed circuit board below. A return spring pushes the key back up when the pressure is released. The foam dampens the contact, helping to prevent bounce, but unfortunately it gives these keyboards a "mushy" feel. The big problem with this type of keyswitch design is that little tactile feedback often exists. These types of keyboards send a clicking sound to the system speaker to signify that contact has been made. Preferences in keyboard feel are somewhat subjective; I personally do not favor the foam element switch design.

Another problem with this type of design is that it is more subject to corrosion on the foil conductor and the circuit board traces below. When this happens, the key strikes can become intermittent, which can be frustrating. Fortunately, these keyboards are among the easiest to clean. By disassembling the keyboard completely, you usually can remove the circuit board portion—without removing each foam pad separately—and expose the bottoms of all the pads. Then, you easily can wipe the corrosion and dirt off the bottoms of the foam pads and the circuit board, thus restoring the keyboard to a "like-new" condition. Unfortunately, over time, the corrosion problem will occur again. I recommend using some Stabilant 22a from D.W. Electrochemicals to improve the switch contact action and prevent future corrosion. Because of such problems, the foam element design is not used much anymore and has been superseded in popularity by the rubber dome design.

Key Tronic, the most well-known user of this technology, now uses a center-bearing membrane switch technology in its mid-range and high-end keyboards, so you are likely to encounter foam-switch keyboards only on older systems.

Rubber Dome Switches

Rubber dome switches are mechanical switches similar to the foam element type but are improved in many ways. Instead of a spring, these switches use a rubber dome that has a carbon button contact on the underside. As you press a key, the key plunger presses on the rubber dome, causing it to resist and then collapse all at once, much like the top of an oil can. As the rubber dome collapses, the user feels the tactile feedback, and the carbon button makes contact between the circuit board traces below. When the key is released, the rubber dome re-forms and pushes the key back up.

The rubber eliminates the need for a spring and provides a reasonable amount of tactile feedback without any special clips or other parts. Rubber dome switches use a carbon button because it resists corrosion and has a self-cleaning action on the metal contacts below. The rubber domes themselves are formed into a sheet that completely protects the contacts below from dirt, dust, and even minor spills. This type of switch design is the simplest, and it uses the fewest parts. This made the rubber dome keyswitch very reliable for several years. However, its relatively poor tactile feedback has led most keyboard manufacturers to switch to the membrane switch design covered in the next section.

Membrane Switches

The membrane keyswitch is a variation on the rubber dome type, using a flat, flexible circuit board to receive input and transmit it to the keyboard microcontroller. Industrial versions of membrane boards use a single sheet for keys that sits on the rubber dome sheet for protection against harsh environments. This arrangement severely limits key travel. For this reason, flat-surface membrane keyboards are not considered usable for normal touch typing. However, they are ideal for use in extremely harsh environments. Because the sheets can be bonded together and sealed from the elements, membrane keyboards can be used in situations in which no other type could survive. Many industrial applications use membrane keyboards for terminals that do not require extensive data entry but are used instead to operate equipment, such as cash registers and point-of-sale terminals in restaurants.

Membrane keyswitches are no longer relegated to fast food or industrial uses, though. Over the last few years, the membrane keyswitch used with conventional keyboard keytops has replaced the rubber dome keyswitch to become the most popular keyswitch used in low-cost to mid-range keyboards. Inexpensive to make, membrane switches have become the overwhelming favorite of low-cost Pacific Rim OEM suppliers and are found in most of the keyboards you'll see at your local computer store or find inside the box of your next complete PC. Although low-end membrane keyswitches have a limited life of only 5–10 million keystrokes, some of the better models are rated to handle up to 20 million keystrokes, putting them in the range of pure mechanical switches for durability (see Figure 18.5).

Membrane keyboards provide a firmer touch than rubber dome keyboards or the old foam-element keyboards, but they are still no match for mechanical or capacitive keyswitch models in their feel. One interesting exception is the line of keyboards made by Key Tronic using its center-bearing version of membrane keyswitches. Several of its keyboards feature Ergo Technology, which has five levels of force from 35 grams to 80 grams, depending on the relative strength of the fingers used to type various keys. As little as 35 grams of force is required for keys that are used by the little finger, such as Q, Z, and A, and greater levels of force are required for keys used by the other fingers. The spacebar requires the most force: 80 grams. This compares to the standard force level of 55 grams for all keys on normal keyboards (see Figure 18.6). For more information about keyboards with Ergo Technology, visit Key Tronic's Web site (`www.keytronic.com`).

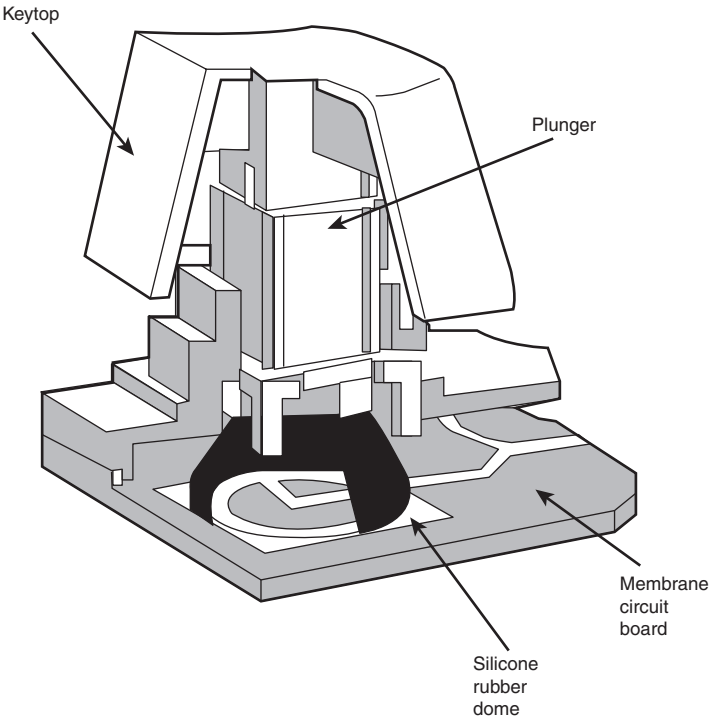

Figure 18.5 A typical membrane keyswitch used in NMB keyboards.

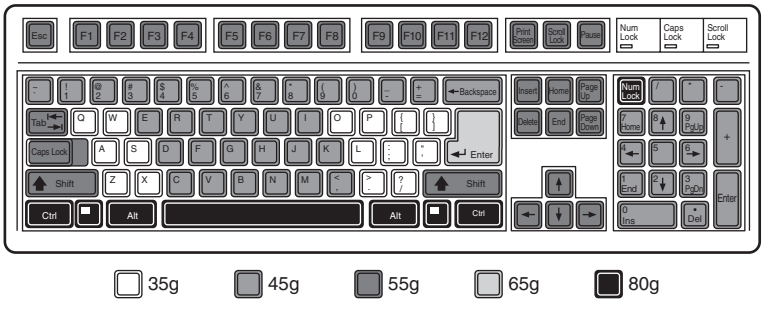

Figure 18.6 Force levels used on Key Tronic keyboards with Ergo Technology.

To find the best membrane keyboards from the vast numbers on the market, look at the lifespan rating of the keyswitches. Longer-lasting keyswitches make the keyboard cost more but will lead to a better experience over the life of the keyboard.

Capacitive Switches

Capacitive switches are the only nonmechanical keyswitch in use today (see Figure 18.7). The capacitive switch is the Cadillac of keyswitches. It is much more expensive than the more common

mechanical membrane switch, but it is more resistant to dirt and corrosion and offers the highest-quality tactile feedback of any type of switch. This type of keyboard is sometimes referred to as a *buckling spring* keyboard because of the coiled spring used to provide feedback.

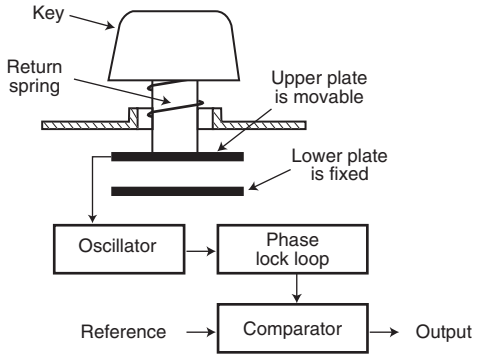

Figure 18.7 A capacitive buckling spring keyswitch.

A capacitive switch does not work by making contact between conductors. Instead, two plates usually made of plastic are connected in a switch matrix designed to detect changes in the capacitance of the circuit.

When the key is pressed, the plunger moves the top plate in relation to the fixed bottom plate. Typically, a buckling spring mechanism provides for a distinct over-center tactile feedback with a resounding "click." As the top plate moves, the capacitance between the two plates changes. The comparator circuitry in the keyboard detects this change.

Because this type of switch does not rely on metal contacts, it is nearly immune to corrosion and dirt. These switches are also very resistant to the key bounce problems that result in multiple characters appearing from a single strike. In addition, they are the most durable in the industry—rated for 25 million or more keystrokes, as opposed to 10–20 million for other designs. The tactile feedback is unsurpassed because the switch provides a relatively loud click and a strong over-center feel. The only drawback to the design is the cost. Capacitive switch keyboards are among the most expensive designs. The quality of the feel and their durability make them worth the price, however.

Originally, the only vendor of capacitive keyswitch keyboards was IBM. Although some of IBM's keyboards still feature capacitive keyswitches, many IBM keyboards also use rubber-dome or other lower-cost keyswitches. In 1991, IBM spun off its keyboard/printer division as Lexmark, which then spun off the keyboard division as Unicomp in 1996. Today, Unicomp still manufactures and sells "IBM" keyboards with the classic buckling spring capacitive switch ("clickety" as some would say) technology. As a bonus, it also has models with the IBM trackpoint built in. You can purchase new Unicomp (IBM) keyboards direct by calling its toll-free number (800-777-4886) or by visiting its online store (`http://www.pckeyboard.com`).

My personal recommendations are for either the EnduraPro/104 for $99 (`http://www.pckeyboard.com/ep104.html`) or the Customizer 101 or 104, which is available in a 101-key buckling spring keyswitch version for only $49 (`http://www.pckeyboard.com/customizer.html`). These are brand-new, not reconditioned or rebuilt, keyboards.

The EnduraPro/104 is notable for including a built-in trackpoint and a pass-through mini-DIN mouse port, being programmable and reconfigurable, requiring no special drivers, and of course having the famous buckling spring keyswitches.

Because of the buckling spring capacitive keyswitches (and the resulting clickety feel), I've always been a huge fan of the IBM, Lexmark, and now Unicomp keyboards. In my opinion, they are the absolute best keyboards in the world and the only ones I willingly use on desktop systems. I especially like the fact that they include the IBM TrackPoint because I use a laptop system as my main machine and therefore use only laptops that include the TrackPoint device (mainly IBM, Toshiba, and some Dell/HP/others). The feel and durability of the buckling spring capacitive keyswitches is outstanding, and with the integrated TrackPoint, I never have to move my hands off the keyboard, resulting in much greater efficiency when working with my systems.

The Keyboard Interface

A keyboard consists of a set of switches mounted in a grid or an array called the *key matrix*. When a switch is pressed, a processor in the keyboard identifies which key is pressed by determining which grid location in the matrix shows continuity. The keyboard processor, which also interprets how long the key is pressed, can even handle multiple keypresses at the same time. A 16-byte hardware buffer in the keyboard can handle rapid or multiple keypresses, passing each one to the system in succession.

When you press a key, the contact bounces slightly in most cases, meaning that several rapid on/off cycles occur just as the switch makes contact. This is called *bounce*. The processor in the keyboard is designed to filter this, or *debounce* the keystroke. The keyboard processor must distinguish bounce from a double key strike the keyboard operator intends to make. This is fairly easy, though, because the bouncing is much more rapid than a person could simulate by striking a key quickly several times.

The keyboard in a PC is actually a computer itself. It communicates with the main system in one of two ways:

- Through a special serial data link if a standard keyboard connector is used
- Through the USB port

The serial data link used by conventional keyboards transmits and receives data in 11-bit packets of information, consisting of 8 data bits, plus framing and control bits. Although it is indeed a serial link (in that the data flows on one wire), the keyboard interface is incompatible with the standard RS-232 serial port commonly used to connect modems.

The processor in the original PC keyboard was an Intel 8048 microcontroller chip. Newer keyboards often use an 8049 version that has built-in ROM or other microcontroller chips compatible with the 8048 or 8049. For example, in its Enhanced keyboards, IBM has always used a custom version of the Motorola 6805 processor, which is compatible with the Intel chips. The keyboard's built-in processor reads the key matrix, debounces the keypress signals, converts the keypress to the appropriate scan code, and transmits the code to the motherboard. The processors built into the keyboard contain their own RAM, possibly some ROM, and a built-in serial interface.

In the original PC/XT design, the keyboard serial interface is connected to an 8255 Programmable Peripheral Interface (PPI) chip on the motherboard of the PC/XT. This chip is connected to the interrupt controller IRQ1 line, which is used to signal to the system that keyboard data is available. The data is then sent from the 8255 to the processor via I/O port address 60h. The IRQ1 signal causes the main system processor to run a subroutine (INT 9h) that interprets the keyboard scan code data and decides what to do.

In an AT-type keyboard design, the keyboard serial interface is connected to a special keyboard controller on the motherboard. This controller was an Intel 8042 Universal Peripheral Interface (UPI) slave microcontroller chip in the original AT design. This microcontroller is essentially another

processor that has its own 2KB of ROM and 128 bytes of RAM. An 8742 version that uses erasable programmable read-only memory (EPROM) can be erased and reprogrammed. In the past, when you purchased a motherboard ROM upgrade for an older system from a motherboard manufacturer, the upgrade included a new keyboard controller chip as well because it had somewhat dependent and updated ROM code in it. Some older systems might use the 8041 or 8741 chips, which differ only in the amount of built-in ROM or RAM. However, recent systems incorporate the keyboard controller into the main system chipset.

In an AT system, the (8048-type) microcontroller in the keyboard sends data to the (8042-type) keyboard controller on the motherboard. The motherboard-based controller also can send data back to the keyboard. When the keyboard controller on the motherboard receives data from the keyboard, it signals the motherboard with an IRQ1 and sends the data to the main motherboard processor via I/O port address 60h, just as in the PC/XT. Acting as an agent between the keyboard and the main system processor, the 8042-type keyboard controller can translate scan codes and perform several other functions as well. The system also can send data to the 8042 keyboard controller via port 60h, which then passes it on to the keyboard. Additionally, when the system needs to send commands to or read the status of the keyboard controller on the motherboard, it reads or writes through I/O port 64h. These commands usually are followed by data sent back and forth via port 60h.

In older systems, the 8042 keyboard controller is also used by the system to control the A20 memory address line, which provides access to system memory greater than 1MB. More modern motherboards typically incorporate this functionality directly into the motherboard chipset. The AT keyboard connector was renamed the "PS/2" port after the IBM PS/2 family of systems debuted in 1987. That was the time when the connector changed in size from the DIN to the min-DIN, and even though the signals were the same, the mini-DIN version became known from that time forward as the PS/2 port.

Keyboards connected to a USB port work in a surprisingly similar fashion to those connected to conventional DIN or mini-DIN (PS/2) ports after the data reaches the system. Inside the keyboard a variety of custom controller chips is used by various keyboard manufacturers to receive and interpret keyboard data before sending it to the system via the USB port. Some of these chips contain USB hub logic to enable the keyboard to act as a USB hub. After the keyboard data reaches the USB port on the system, the USB port routes the data to the 8042-compatible keyboard controller, where the data is treated as any other keyboard information.

This process works very well after a system has booted into Windows. But what about users who need to use the keyboard at a command prompt or within the BIOS configuration routine? As discussed earlier in this chapter, USB Legacy support must be enabled in the BIOS. A BIOS with USB Legacy support is capable of performing the following tasks:

- Configure the host controller
- Enable a USB keyboard and mouse
- Set up the host controller scheduler
- Route USB keyboard and mouse input to the 8042 Keyboard Controller

Systems with USB Legacy support enabled use the BIOS to control the USB keyboard until a supported operating system is loaded. At that point, the USB host controller driver in the operating system takes control of the keyboard by sending a command called `StopBIOS` to the BIOS routine that was managing the keyboard. When Windows shuts down to MS-DOS, the USB host controller sends a command called `StartBIOS` to restart the BIOS routine that manages the keyboard.

When the BIOS controls the keyboard, after the signals reach the 8042 Keyboard Controller, the USB keyboard is treated just like a conventional keyboard if the BIOS is correctly designed to work with

USB keyboards. As discussed previously in this chapter, a BIOS upgrade might be necessary in some cases to provide proper support of USB keyboards on some systems. The system chipset also must support USB Legacy features.

Typematic Functions

If a key on the keyboard is held down, it becomes *typematic*, which means the keyboard repeatedly sends the keypress code to the motherboard. In the AT-style keyboards, the typematic rate is adjusted by sending the appropriate commands to the keyboard processor. This is impossible for the earlier PC/XT keyboard types because the keyboard interface for these types is not bidirectional.

AT-style keyboards have programmable typematic repeat rate and delay parameters. You can adjust the typematic repeat rate and delay parameters with settings in your system BIOS (although not all BIOS chips can control all functions) or in your operating system. In Windows you use the Keyboard icon in the Control Panel; in DOS you use the `MODE` command. The next section describes how to adjust the keyboard parameters in Windows because this is more convenient than the other methods and enables the user to make further adjustments at any time without restarting the system.

Adjusting Keyboard Parameters in Windows

You can modify the default values for the typematic repeat rate and delay parameters in any version of Windows using the Keyboard icon in the Control Panel. The Repeat Delay slider controls the number of times a key must be pressed before the character begins to repeat, and the Repeat Rate slider controls how fast the character repeats after the delay has elapsed.

Note

The increments on the Repeat Delay and Repeat Rate sliders in Keyboard Properties in the Control Panel correspond to the timings given for the `MODE` command's `RATE` and `DELAY` values. Each mark in the Repeat Delay slider adds about 0.25 seconds to the delay, and the marks in the Repeat Rate slider are worth about one character per second each.

The dialog box also contains a text box you can use to test the settings you have chosen before committing them to your system. When you click in the box and press a key, the keyboard reacts using the settings currently specified by the sliders, even if you have not yet applied the changes to the Windows environment.

To learn how to adjust keyboard parameters in DOS, see "Adjusting Keyboard Parameters in DOS" in Chapter 17 of *Upgrading and Repairing PCs, 11th Edition*, which is available in electronic form on the DVD-ROM included with this book.

Keyboard Key Numbers and Scan Codes

When you press a key on the keyboard, the processor built into the keyboard (8048- or 6805-type) reads the keyswitch location in the keyboard matrix. The processor then sends to the motherboard a serial packet of data containing the scan code for the key that was pressed.

This is called the *Make code*. When the key is released, a corresponding *Break code* is sent, indicating to the motherboard that the key has been released. The Break code is equivalent to the Make scan code plus 80h. For example, if the Make scan code for the "A" key is 1Eh, the Break code would be 9Eh. By using both Make and Break scan codes, the system can determine whether a particular key has been held down and determine whether multiple keys are being pressed.

In AT-type motherboards that use an 8042-type keyboard controller, the 8042 chip translates the actual keyboard scan codes into one of up to three sets of system scan codes, which are sent to the

main processor. It can be useful in some cases to know what these scan codes are, especially when troubleshooting keyboard problems or when reading the keyboard or system scan codes directly in software.

When a keyswitch on the keyboard sticks or otherwise fails, the Make scan code of the failed keyswitch usually is reported by diagnostics software, including the power on self test (POST), as well as conventional disk-based diagnostics. This means you must identify the malfunctioning key by its scan code. See the Technical Reference section of the DVD included with this book for a comprehensive listing of keyboard key numbers and scan codes for both the 101/102-key (Enhanced) keyboard and 104-key Windows keyboard. By looking up the reported scan code on these charts, you can determine which keyswitch is defective or needs to be cleaned.

Note

The 101-key Enhanced keyboards are capable of three scan code sets. Set 1 is the default. Some systems, including some of the IBM PS/2 machines, use one of the other scan code sets during the POST. For example, my IBM P75 uses Scan Code Set 2 during the POST but switches to Set 1 during normal operation. This is rare, and it really threw me off in diagnosing a stuck key problem one time. It is useful to know whether you are having difficulty interpreting the scan code number, however.

IBM also assigns each key a unique key number to distinguish it from the others. This is important when you are trying to identify keys on foreign keyboards that might use symbols or characters different from what the U.S. models do. In the Enhanced keyboard, most foreign models are missing one of the keys (key 29) found on the U.S. version and have two additional keys (keys 42 and 45). This accounts for the 102-key total instead of the 101 keys found on the U.S. version.

Note

See the Technical Reference section of the DVD included with this book for a comprehensive listing of keyboard key numbers and scan codes for both the 101/102-key (Enhanced) keyboard and 104-key Windows keyboard, including HID and hotkey scan codes used on the latest USB and hotkey keyboards.

Knowing these key number figures and scan codes can be useful when you are troubleshooting stuck or failed keys on a keyboard. Diagnostics can report the defective keyswitch by the scan code, which varies from keyboard to keyboard on the character it represents and its location.

Many enhanced and USB keyboards now feature hotkeys that either have fixed uses—such as opening the default Web browser, sending the system into standby mode, and adjusting the speaker volume—or are programmable for user-defined functions. Each of these keys also has scan codes. USB keyboards use a special series of codes called Human Interface Device (HID), which are translated into PS/2 scan codes.

International Keyboard Layouts

After the keyboard controller in the system receives the scan codes generated by the keyboard and passes them to the main processor, the operating system converts the codes into the appropriate alphanumeric characters. In the United States, these characters are the letters, numbers, and symbols found on the standard American keyboard.

However, no matter which characters you see on the keytops, adjusting the scan code conversion process to map different characters to the keys is relatively simple. Windows (post 3.x) takes advantage of this capability by enabling you to install multiple keyboard layouts to support various languages.

In Windows 9x/Me, open the Keyboard icon in the Control Panel and select the Language page. The Language box should display the keyboard layout you selected when you installed the operating system. In Windows XP, click the Details button found on the Languages tab in the Regional and Language Options applet (in the Windows Control Panel). By clicking the Add button, you can select any one of several additional keyboard layouts supporting other languages.

These keyboard layouts map various characters to certain keys on the standard keyboard. The standard French layout provides easy access to the accented characters commonly used in that language. For example, pressing the 2 key produces the é character. To type the numeral 2, you press the Shift+2 key combination. Other French-speaking countries have different keyboard conventions for the same characters, so Windows includes support for several keyboard layout variations for some languages, based on nationality.

Note

It is important to understand that this feature is not the same as installing the operating system in a different language. These keyboard layouts do not modify the text already displayed onscreen; they only alter the characters generated when you press certain keys.

The alternative keyboard layouts also do not provide support for non-Roman alphabets, such as Russian and Chinese. The accented characters and other symbols used in languages such as French and German are part of the standard ASCII character set. They are always accessible to English-language users through the Windows Character Map utility or through the use of Alt+keypad combinations. An alternative keyboard layout simply gives you an easier way to access the characters used in certain languages.

If you work on documents using more than one language, you can install as many keyboard layouts as necessary and switch between them at will. When you click the Enable Indicator on Taskbar check box on the Language page of the Keyboard control panel, a selector appears in the taskbar's tray area that enables you to switch languages easily. On the same page, you can enable a key combination that switches between the installed keyboard layouts.

Keyboard/Mouse Interface Connectors

Keyboards have a cable with one of two primary types of connectors at the system end. On most aftermarket keyboards, the cable is connected inside the keyboard case on the keyboard end, requiring you to open the keyboard case to disconnect or test it; different vendors use different connections, making cable interchange between brands of keyboards unlikely. When IBM manufactured its own enhanced keyboards, it used a unique cable assembly that plugged into both the keyboard and the system unit to make cable replacement or interchange easy. Current IBM keyboards, unfortunately, no longer use either the shielded data link (SDL) connector inside the keyboard or the telephone cable-style removable plug-in external keyboard connector used on some more recent models.

Although the method of connecting the keyboard cable to the keyboard can vary, all PC keyboards (except those using the USB port) use either of the following two connectors to attach to the computer:

- *5-pin DIN connector.* Used on most PC systems with Baby-AT form factor motherboards
- *6-pin mini-DIN connector.* Used on PS/2 systems and most PCs with LPX, ATX, and NLX motherboards

Figure 18.8 and Table 18.2 show the physical layout and pinouts of all the respective keyboard connector plugs and sockets; although the 6-pin SDL connector is not used in this form by most

keyboard vendors, most non-IBM keyboards use a somewhat similar connector to attach the keyboard cable to the inside of the keyboard. You can use the pinouts listed in Table 18.2 to test the continuity of each wire in the keyboard connector.

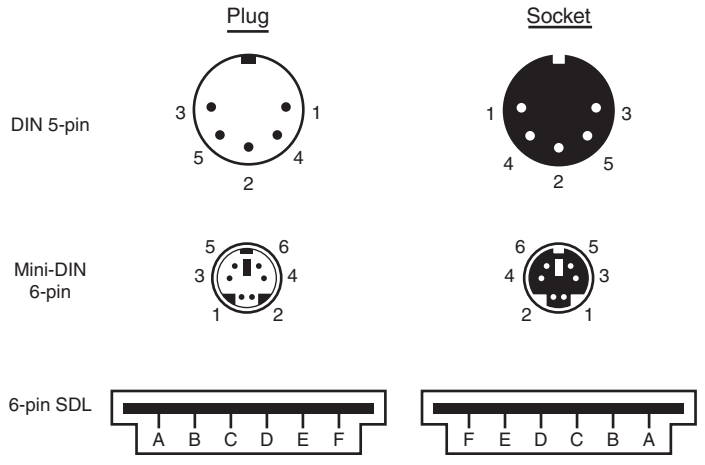

Figure 18.8 Keyboard and mouse connectors.

Table 18.2 Keyboard Connector Signals and Specifications

Signal Name	5-Pin DIN	6-Pin Mini-DIN	6-Pin SDL	Test Voltage
Keyboard Data	2	1	B	+4.8v to +5.5v
Ground	4	3	C	—
+5v Power	5	4	E	+2.0v to +5.5v
Keyboard Clock	1	5	D	+2.0v to +5.5v
Not Connected	—	2	A	—
Not Connected	—	6	F	—
Not Connected	3	—	—	—

DIN = Deutsche Industrie Norm, a committee that sets German dimensional standards

SDL = Shielded data link, a type of shielded connector created by AMP and used by IBM and others for keyboard cables

Motherboard non-USB mouse connectors also use the 6-pin mini-DIN connector and have the same pinout and signal descriptions as the keyboard connector; however, the data packets are incompatible. Therefore, you can easily plug a motherboard mouse (PS/2-style) into a mini-DIN keyboard connector or plug the mini-DIN keyboard connector into a motherboard mouse port. Neither one will work properly in this situation, though.

Caution

I have also seen PCs with external power supplies that used the same standard DIN connectors to attach the keyboard and power supply. Although cross-connecting the mini-DIN connectors of a mouse and keyboard is a harmless annoyance, connecting a power supply to a keyboard socket can be disastrous.

USB keyboards use the Series A USB connector to attach to the USB port built into modern computers. For more information on USB, see Chapter 17, "I/O Interfaces from Serial and Parallel to IEEE-1394 and USB."

Keyboards with Special Features

Several keyboards on the market have special features not found in standard designs. These additional features range from simple things, such as built-in calculators, clocks, and volume control, to more complicated features, such as integrated pointing devices, special character layouts, shapes, and even programmable keys.

Note

In 1936, August Dvorak patented a simplified character layout called the Dvorak Simplified Keyboard (DSK). The Dvorak keyboard was designed to replace the common QWERTY layout used on nearly all keyboards available today. The Dvorak keyboard was approved as an ANSI standard in 1982 but has seen limited use. For a comparison between the Dvorak keyboard and the common QWERTY keyboard you most likely use, see "The Dvorak Keyboard" in the Technical Reference section of the DVD accompanying this book.

Ergonomic Keyboards

A trend that began in the late 1990s is to change the shape of the keyboard instead of altering the character layout. This trend has resulted in several so-called ergonomic designs. The goal is to shape the keyboard to better fit the human hand. The most common of these designs splits the keyboard in the center, bending the sides outward. Some designs allow the angle between the sides to be adjusted, such as the now-discontinued Lexmark Select-Ease, the Goldtouch keyboard designed by Mark Goldstein (who also designed the Select-Ease), and the Kenisis Maxim split keyboards. Others, such as the Microsoft Natural keyboard series, PC Concepts Wave, and Cirque Smooth Cat, are fixed. These split or bent designs more easily conform to the hands' natural angles while typing than the standard keyboard. They can improve productivity and typing speed and help prevent repetitive strain injuries (RSI), such as carpal tunnel syndrome (tendon inflammation). Even more radical keyboard designs are available from some vendors, including models such as the 3-part Comfort and ErgoMagic keyboards, the Kinisis concave contoured keyboard, and others. A good source for highly ergonomic keyboards, pointing devices, and furniture is Ergonomic Resources (`www.ergo-2000.com`).

One of the most popular ergonomic keyboards, the Microsoft Natural Keyboard Elite, is manufactured for Microsoft by Key Tronic. It uses the inexpensive soft-touch rubber dome keyswitches Key Tronic is known for. If you're looking for a more rugged keyboard with a firmer touch, try the Kinisis Maxim.

Because of their novelty and trendy appeal, some ergonomic keyboards can be considerably more expensive than traditional designs, but for users with medical problems caused or exacerbated by improper positioning of the wrists at the keyboard, they can be an important remedy to a serious problem. General users, however, are highly resistant to change, and these designs have yet to significantly displace the standard keyboard layout. If you don't want to spend big bucks on the more radical ergonomic keyboards but want to give yourself at least limited protection from RSI, consider keyboards with a built-in wrist rest or add a gel-based wrist rest to your current keyboard. These provide hand support without making you learn a modified or brand-new keyboard layout.

USB Keyboards with Hubs

Some of the latest USB keyboards feature a built-in USB hub designed to add two or more USB ports to your system. Even though this sounds like a good idea, keep in mind that a keyboard-based hub won't provide additional power to the USB connectors. Powered hubs work better with a wider variety

of devices than unpowered hubs do. I wouldn't choose a particular model based solely on this feature, although if your keyboard has it and your devices work well when plugged into it, that's great. I'd recommend that you use this type of keyboard with your USB mouse or other devices that don't require much power.

Multimedia and Web-Enabled Keyboards

As I discussed earlier in this chapter, many keyboards sold at retail and bundled with systems today feature fixed-purpose or programmable hotkeys that can launch Web browsers, run the Microsoft Media Player, adjust the volume on the speakers, change tracks on the CD player, and so forth. You need Windows 98 or later to use these hotkeys; Windows Me, Windows 2000, and Windows XP add additional support for these keyboards.

Keyboard Troubleshooting and Repair

Keyboard errors are usually caused by two simple problems. Other more difficult, intermittent problems can arise, but they are much less common. The most frequent problems are as follows:

- Defective cables
- Stuck keys

Defective cables are easy to spot if the failure is not intermittent. If the keyboard stops working altogether or every keystroke results in an error or incorrect character, the cable is likely the culprit. Troubleshooting is simple, especially if you have a spare cable on hand. Simply replace the suspected cable with one from a known, working keyboard to verify whether the problem still exists. If it does, the problem must be elsewhere.

If you remove the cable from the keyboard, you can test it for continuity with a digital multimeter (DMM). DMMs that have an audible continuity tester built in make this procedure much easier to perform. To test each wire of the cable, insert the DMM's red pin into the keyboard connector and touch the DMM's black pin to the corresponding wire that attaches to the keyboard's circuit board. Wiggle the ends of the cable as you check each wire to ensure no intermittent connections exist. If you discover a problem with the continuity in one of the wires, replace the cable or the entire keyboard, whichever is cheaper. Because replacement keyboards are so inexpensive, it's almost always cheaper to replace the entire unit than to get a new cable, unless the keyboard is a deluxe model.

For more information about using digital multimeters for testing hardware, see Chapter 23, "PC Diagnostics, Testing, and Maintenance."

Many times you first discover a problem with a keyboard because the system has an error during the POST. Many systems use error codes in a 3xx numeric format to distinguish the keyboard. If you encounter any such errors during the POST, write them down. Some BIOS versions do not use cryptic numeric error codes; they simply state something such as the following:

```
Keyboard stuck key failure
```

This message is usually displayed by a system with a Phoenix BIOS if a key is stuck. Unfortunately, the message does not identify which key it is!

If your system displays a 3xx (keyboard) error preceded by a two-digit hexadecimal number, the number is the scan code of a failing or stuck keyswitch. Look up the scan code in the tables provided in the Technical Reference section on the DVD to determine which keyswitch is the culprit. By removing the keycap of the offending key and cleaning the switch, you often can solve the problem.

For a simple test of the motherboard keyboard connector, you can check voltages on some of the pins. Using Figure 18.8, which was shown earlier in the chapter, as a guide, measure the voltages on

various pins of the keyboard connector. To prevent possible damage to the system or keyboard, turn off the power before disconnecting the keyboard. Then, unplug the keyboard and turn the power back on. Make measurements between the ground pin and the other pins according to Table 18.2, shown earlier in the chapter. If the voltages are within these specifications, the motherboard keyboard circuitry is probably okay.

If your measurements do not match these voltages, the motherboard might be defective. Otherwise, the keyboard cable or keyboard might be defective. If you suspect that the cable is the problem, the easiest thing to do is replace the keyboard cable with a known good one. If the system still does not work normally, you might have to replace the entire keyboard or the motherboard.

In many newer systems, the motherboard's keyboard and mouse connectors are protected by a fuse that can be replaced. Look for any type of fuse on the motherboard in the vicinity of the keyboard or mouse connectors. Other systems might have a socketed keyboard controller chip (8042-type). In that case, you might be able to repair the motherboard keyboard circuit by replacing this chip. Because these chips have ROM code in them, you should get the replacement from the motherboard or BIOS manufacturer. If the motherboard uses a soldered keyboard controller chip or a chipset that integrates the keyboard controller with other I/O chips, you'll need to replace the motherboard.

See the DVD-ROM included with this book for a listing of the standard POST and diagnostic keyboard error codes used by some systems.

Keyboard Disassembly

Although disassembling a keyboard is possible, most likely you won't need or want to do that given the reasonable prices of keyboards. If you do want to disassemble your keyboard, see "Keyboard Disassembly" in the Technical Reference section of the DVD accompanying this book.

Cleaning a Keyboard

One of the best ways to keep a keyboard in top condition is periodic cleaning. As preventive maintenance, you should vacuum the keyboard weekly, or at least monthly. When vacuuming, you should use a soft brush attachment; this will help dislodge the dust. Also note that many keyboards have keycaps that can come off easily. Be careful when vacuuming; otherwise, you'll have to dig them out of the vacuum cleaner.

You also can use canned compressed air to blow the dust and dirt out instead of using a vacuum. Before you dust a keyboard with the compressed air, turn the keyboard upside down so that the particles of dirt and dust collected inside can fall out.

On all keyboards, each keycap is removable, which can be handy if a key sticks or acts erratically. For example, a common problem is a key that does not work every time you press it. This problem usually results from dirt collecting under the key. An excellent tool for removing keycaps on almost any keyboard is the U-shaped chip puller included in many computer tool kits. Simply slip the hooked ends of the tool under the keycap, squeeze the ends together to grip the underside of the keycap, and lift up. IBM sells a tool designed specifically for removing keycaps from its keyboards, but the chip puller works even better. After removing the cap, spray some compressed air into the space under the cap to dislodge the dirt. Then replace the cap and check the action of the key.

Caution

When you remove the keycaps, be careful not to remove the spacebar on the original 83-key PC and the 84-key AT-type keyboards. This bar is difficult to reinstall. The newer 101-key units use a different wire support that can be removed and replaced much more easily.

When you remove the keycap on some keyboards, you are actually detaching the entire key from the keyswitch. Be careful during the removal or reassembly of the keyboard; otherwise, you'll break the switch. The classic IBM/Lexmark-type keyboards (now made by Unicomp) use a removable keycap that leaves the actual key in place, enabling you to clean under the keycap without the risk of breaking the switches.

Spills can be a problem, too. If you spill a soft drink or cup of coffee into a keyboard, you do not necessarily have a disaster. Many keyboards that use membrane switches are spill resistant. However, you should immediately (or as soon as possible) disconnect the keyboard and flush it out with distilled water. Partially disassemble the keyboard and use the water to wash the components. (See "Keyboard Disassembly" in the Technical Reference section of the DVD accompanying this book for disassembly instructions.) If the spilled liquid has dried, soak the keyboard in some of the water for a while. When you are sure the keyboard is clean, pour another gallon or so of distilled water over it and through the keyswitches to wash away any residual dirt. After the unit dries completely, it should be perfectly functional. You might be surprised to know that drenching your keyboard with water does not harm the components. Just make sure you use distilled water, which is free from residue or mineral content (bottled water is *not* distilled; the distinct taste of many bottled waters comes from the trace minerals they contain!). Also, make sure the keyboard is fully dry before you try to use it; otherwise, some of the components might short out.

Tip

If spills or excessive dust or dirt are expected because of the environment or conditions in which the PC is used, several companies make thin membrane skins that mold over the top of the keyboard, protecting it from liquids, dust, and other contaminants. These skins are generally thin enough so that they don't interfere too much with the typing or action of the keys.

Keyboard Recommendations

In most cases, replacing a keyboard is cheaper or more cost effective than repairing it. This is especially true if the keyboard has an internal malfunction or if one of the keyswitches is defective. Replacement parts for keyboards are almost impossible to procure, and installing any repair part is usually difficult. In addition, many of the keyboards supplied with lower-cost PCs leave much to be desired. They often have a mushy feel, with little or no tactile feedback. A poor keyboard can make using a system a frustrating experience, especially if you are a touch typist. For all these reasons, it is often a good idea to replace an existing keyboard with something better.

Perhaps the highest-quality keyboards in the entire computer industry are those made by IBM, or, more accurately today, Unicomp. Unicomp maintains an extensive selection of more than 1,400 Lexmark and IBM keyboard models and continues to develop and sell a wide variety of traditional and customized models, including keyboards that match the school colors of several universities.

Note

See the section "Replacement Keyboards" in Chapter 17 of *Upgrading and Repairing PCs, 11th Edition* on this book's DVD for a listing of IBM keyboard and cable part numbers.

Some of the classic-design IBM keyboards are available in the retail market under either the IBM or IBM Options brand name. Items under the IBM Options program are sold through normal retail channels, such as CompUSA and Computer Discount Warehouse (CDW). These items are also priced much more cheaply than items purchased as spare parts. They include a full warranty and are sold as complete packages, including cables. Table 18.3 lists some of the IBM Options keyboards and part numbers. Models marked with an * are also available from Unicomp.

Table 18.3 IBM Options Keyboards (Sold Retail)

Description	Part Number
IBM Enhanced keyboard (cable w/ DIN plug)	92G7454*
IBM Enhanced keyboard (cable w/ mini-DIN plug)	92G7453*
IBM Enhanced keyboard, built-in Trackball (cable w/ DIN plug)	92G7456*
IBM Enhanced keyboard, built-in Trackball (cable w/ mini-DIN plug)	92G7455*
IBM Enhanced keyboard, integrated TrackPoint II (cables w/ mini-DIN plugs)	92G7461*
IBM TrackPoint IV keyboard, Black	01K1260
IBM TrackPoint IV keyboard, White	01K1259

Keep in mind, though, that because IBM spun off its keyboard business some years ago, many recent and current IBM-labeled keyboards no longer have the distinct feel, quality, or durability found in the older models. Ironically, one of the best ways to get an "IBM" keyboard is to buy the model with the features you want from Unicomp, most of whose keyboards still use the capacitive buckling spring technology IBM originally made famous.

The extremely positive tactile feedback of the IBM/Lexmark/Unicomp design is also a benchmark for the rest of the industry. Although keyboard feel is an issue of personal preference, I have never used a keyboard that feels better than the IBM/Lexmark/Unicomp designs. I now equip every system I use with a Unicomp keyboard, including the many non-IBM systems I use. You can purchase these keyboards directly from Unicomp at very reasonable prices.

Many models are available, including some with a built-in trackball or even the revolutionary TrackPoint pointing device. (TrackPoint refers to a small stick mounted between the G, H, and B keys.) This device was first featured on the IBM ThinkPad laptop systems, although the keyboards are now sold for use on other manufacturers' PCs. The technology is being licensed to many other manufacturers, including Toshiba. Other manufacturers of high-quality keyboards that are similar in feel to the IBM/Lexmark/Unicomp units are Alps, Lite-On, NMB Technologies, and the revived Northgate designs sold under the Avant Prime and Avant Stellar names. These keyboards have excellent tactile feedback, with a positive click sound. They are my second choice, after a Unicomp unit.

Pointing Devices

The mouse was invented in 1964 by Douglas Englebart, who at the time was working at the Stanford Research Institute (SRI), a think tank sponsored by Stanford University. The mouse was officially called an X-Y Position Indicator for a Display System. Xerox later applied the mouse to its revolutionary Alto computer system in 1973. At the time, unfortunately, these systems were experimental and used purely for research.

In 1979, several people from Apple—including Steve Jobs—were invited to see the Alto and the software that ran the system. Steve Jobs was blown away by what he saw as the future of computing, which included the use of the mouse as a pointing device and the graphical user interface (GUI) it operated. Apple promptly incorporated these features into what was to become the Lisa computer and lured away 15–20 Xerox scientists to work on the Apple system.

Although Xerox released the Star 8010 computer that used this technology in 1981, it was expensive, poorly marketed, and perhaps way ahead of its time. Apple released the Lisa computer, its first system that used the mouse, in 1983. It was not a runaway success, largely because of its $10,000 list price, but by then Jobs already had Apple working on the low-cost successor to the Lisa: the Macintosh. The

Apple Macintosh was introduced in 1984. Although it was not an immediate hit, the Macintosh has grown in popularity since that time.

Many credit the Macintosh with inventing the mouse and GUI, but as you can see, this technology was actually borrowed from others, including SRI and Xerox. Certainly the Macintosh, and now Microsoft Windows and OS/2, have gone on to popularize this interface and bring it to the legion of Intel-based PC systems.

Although the mouse did not catch on quickly in the PC marketplace, today the GUIs for PC systems, such as Windows, practically demand the use of a mouse. Therefore, virtually every new system sold at retail comes with a mouse. And, because the mice packaged with retail systems are seldom high-quality or up-to-date designs, sooner or later most users are in the market for a better mouse or compatible pointing device.

Mice come in many shapes and sizes from many manufacturers. Some have taken the standard mouse design and turned it upside down, creating the trackball. In the trackball devices, you move the ball with your hand directly rather than moving the unit itself. Trackballs were originally found on arcade video games, such as Missile Command, but have become popular with users who have limited desk space. In most cases, the dedicated trackballs have a much larger ball than would be found on a standard mouse. Other than the orientation and perhaps the size of the ball, a trackball is identical to a mouse in design, basic function, and electrical interface. Like many recent mice, trackballs often come in ergonomic designs, and the more recent models even use the same optical tracking mechanisms used by the latest Microsoft and Logitech mice.

The largest manufacturers of mice are Microsoft and Logitech; these two companies provide designs that inspire the rest of the industry and each other and are popular OEM choices as well as retail brands. Even though mice can come in different varieties, their actual use and care differ very little. The standard mouse consists of several components:

- A housing that you hold in your hand and move around on your desktop
- A method of transmitting movement to the system: either ball/roller or optical sensors
- Buttons (two or more, and often a wheel or toggle switch) for making selections
- An interface for connecting the mouse to the system; conventional mice use a wire and connector, whereas wireless mice use a radio-frequency or infrared transceiver in both the mouse and a separate unit connected to the computer to interface the mouse to the computer

The housing, which is made of plastic, consists of very few moving parts. On top of the housing, where your fingers normally rest, are buttons. There might be any number of buttons, but in the PC world, two is the standard. If your mouse has additional buttons or a wheel, specialized driver software provided by the mouse vendor is required for them to operate to their full potential. Although the latest versions of Windows support scrolling mice, other features supported by the vendor still require installing the vendor's own mouse driver software.

The bottom of the mouse housing is where the detection mechanisms or electronics are located. On traditional mice, the bottom of the housing contains a small, rubber ball that rolls as you move the mouse across the tabletop. The movements of this rubber ball are translated into electrical signals transmitted to the computer across the cable.

The other major method of motion detection is optical. Some of the early mice made by Mouse Systems and a few other vendors used a sensor that required a special grid-marked pad. Although these mice were very accurate, the need to use them with a pad caused them to fall out of favor.

Microsoft's IntelliMouse Explorer pioneered the return of optical mice, but with a difference. Like the old-style optical mice, the IntelliMouse Explorer uses optical technology to detect movement, and it has no moving parts itself (except for the scroll wheel and buttons on top). The Explorer mouse needs no pad; it can work on virtually any surface. This is done by upgrading the optical sensor from the simple type used in older optical mice to a more advanced CCD (charge coupled device). This essentially is a crude version of a video camera sensor that detects movement by seeing the surface move under the mouse. An LED is used to provide light for the sensor.

The IntelliMouse Explorer is just the first of a growing family of optical mice made by Microsoft (the IntelliMouse Optical and WheelMouse Optical are less expensive versions), and Microsoft also offers an optical-technology trackball. Not to be outdone, Logitech also offers optical mice (including one with two sensors) and optical trackballs using similar technology. Other vendors, such as Kingston and Targus, are now offering optical mice as well (see Figure 18.9).

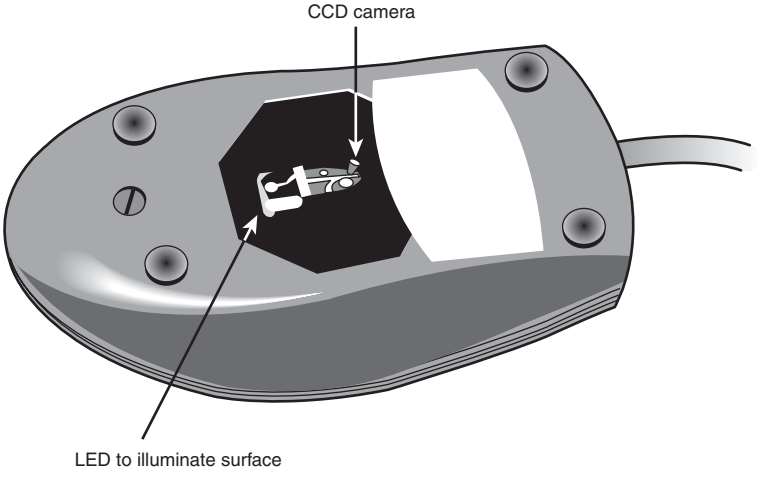

Figure 18.9 The bottom of the Logitech iFeel optical mouse.

Their versatility and low maintenance (not to mention that neat red glow out the sides!) make optical mice an attractive choice, and the variety of models available from both vendors means you can have the latest optical technology for about the price of a good ball-type mouse.

The cable can be any length, but it is typically between 4 and 6 feet long. Mice are also available in a cordless design, which uses either infrared or RF transceivers to replace the cable. A receiver is plugged into the mouse port, while the battery-powered mouse contains a compatible transmitter.

Tip

If you have a choice on the length of cable to buy, get a longer one. This allows easier placement of the mouse in relation to your computer. Extension cables can be used if necessary.

After the mouse is connected to your computer, it communicates with your system through the use of a device driver, which can be loaded explicitly or built into the operating system software. For example, no separate drivers are necessary to use a mouse with Windows or OS/2, but using the mouse with most DOS-based programs requires a separate driver to be loaded from the `CONFIG.SYS` or

AUTOEXEC.BAT file. Regardless of whether it is built in, the driver translates the electrical signals sent from the mouse into positional information and indicates the status of the buttons.

The standard mouse drivers in Windows are designed for the traditional two-button mouse or scroll mouse (in Windows Me/2000/XP or later), but increasing numbers of mice feature additional buttons, toggles, or wheels to make them more useful. These additional features require special mouse driver software supplied by the manufacturer.

Internally, a ball-driven mouse is very simple, too. The ball usually rests against two rollers: one for translating the x-axis movement and the other for translating the y-axis movement. These rollers are typically connected to small disks with shutters that alternately block and allow the passage of light. Small optical sensors detect movement of the wheels by watching an internal infrared light blink on and off as the shutter wheel rotates and "chops" the light. These blinks are translated into movement along the axes. This type of setup, called an *opto-mechanical mechanism*, is by far the most popular in use today (see Figure 18.10). Figure 18.11 shows a PS/2 mouse connector.

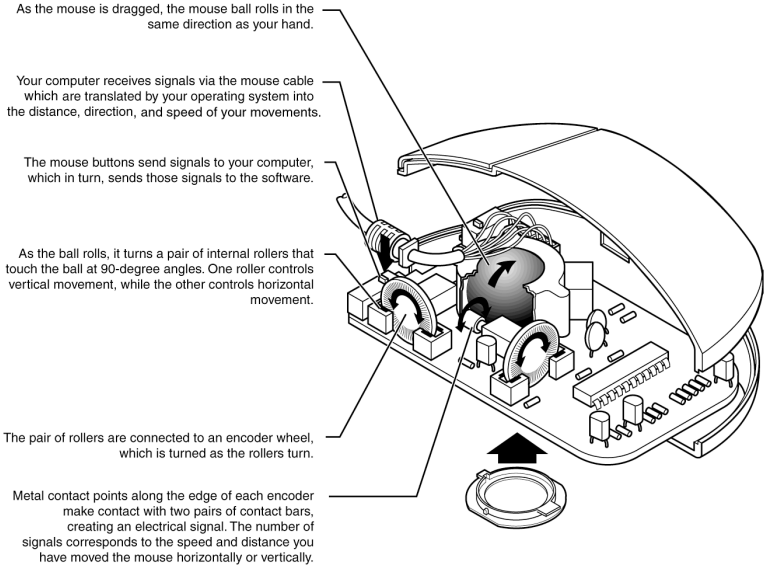

Figure 18.10 Typical opto-mechanical mouse mechanism.

Pointing Device Interface Types

The connector used to attach your mouse to the system depends on the type of interface you are using. Three main interfaces are used for mouse connections, with a fourth option you also occasionally might encounter. Mice are most commonly connected to your computer through the following three interfaces:

- Serial interface
- Dedicated motherboard (PS/2) mouse port
- USB port

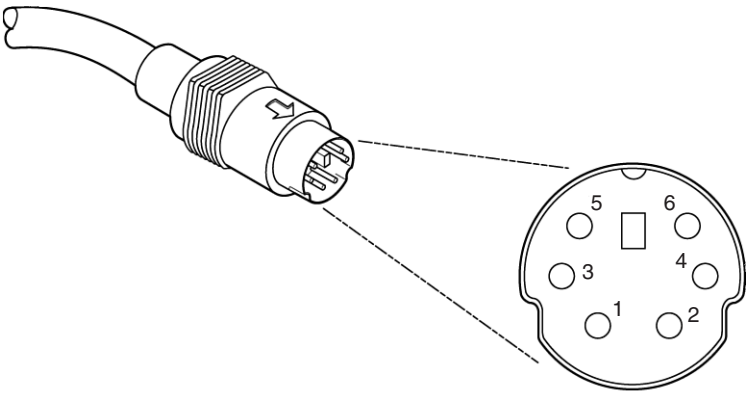

Figure 18.11 Typical PS/2-type mouse connector.

Serial

A popular method of connecting a mouse to older PCs is through the standard serial interface. As with other serial devices, the connector on the end of the mouse cable is typically a 9-pin male connector; some very old mice used a 25-pin male connector. Only a couple of pins in the DB-9 or DB-25 connector are used for communications between the mouse and the device driver, but the mouse connector typically has all 9 or 25 pins present.

Because most PCs come with two serial ports, a serial mouse can be plugged into either COM1 or COM2. The device driver, when initializing, searches the ports to determine to which one the mouse is connected. Some mouse drivers can't function if the serial port is set to COM3 or COM4, but most newer drivers can work with any COM port 1–4.

Because a serial mouse does not connect to the system directly, it does not use system resources by itself. Instead, the resources are those used by the serial port to which it is connected. For example, if you have a mouse connected to COM2, and if COM2 is using the default IRQ and I/O port address range, both the serial port and the mouse connected to it use IRQ3 and I/O port addresses 2F8h–2FFh.

◀◀ See "Serial Ports," p. 975.

Motherboard Mouse Port (PS/2)

Most newer computers now come with a dedicated mouse port built into the motherboard. This practice was introduced by IBM with the PS/2 systems in 1987, so this interface is often referred to as a *PS/2 mouse interface*. This term does not imply that such a mouse can work only with a PS/2; instead, it means the mouse can connect to any system that has a dedicated mouse port on the motherboard.

From a hardware perspective, a motherboard mouse connector is usually exactly the same as the mini-DIN connector used for newer keyboards. In fact, the motherboard mouse port is connected to the 8042-type keyboard controller found on the motherboard. All the PS/2 computers include mini-DIN keyboard and mouse port connectors on the back. Most computers based on the semiproprietary LPX motherboards and all ATX-series motherboards use these same connectors for space reasons. Most Baby-AT motherboards have a pin-header type connector for the mouse port because most standard cases do not have a provision for the mini-DIN mouse connector. If that is the case, an adapter cable is usually supplied with the system. This cable adapts the pin-header connector on the motherboard to the standard mini-DIN type connector used for the motherboard mouse.

Caution

As mentioned in the "Keyboard/Mouse Interface Connectors" section earlier in this chapter, the mini-DIN sockets used for both keyboard and mouse connections on many systems are physically and electrically interchangeable, but the data packets they carry are not. Be sure to plug each device into the correct socket; otherwise, neither will function correctly. Don't panic if you mix them up, though. They are electrically identical to each other, so you can't damage the ports or the devices.

Connecting a mouse to the built-in mouse port is the best method of connection on systems that don't have USB ports because you do not sacrifice any of the system's interface slots or any serial ports, and the performance is not limited by the serial port circuitry. The standard resource usage for a motherboard (or PS/2) mouse port is IRQ12, as well as I/O port addresses 60h and 64h. Because the motherboard mouse port uses the 8042-type keyboard controller chip, the port addresses are those of this chip. IRQ12 is an interrupt that is usually free on most systems, and it, of course, must remain free on any ISA bus systems that have a motherboard mouse port because interrupt sharing is not allowed with the ISA bus.

Hybrid Mice

Hybrid mice are those designed to plug into two types of ports. Most of the low-cost mice sold at retail are designed to plug into either the serial port or the PS/2 port; more expensive mice often plug into either the PS/2 port or the USB port. These combination mice are more flexible than the mice typically bundled with systems, which are designed to work only with the PS/2 or USB port to which they attach.

Circuitry in a hybrid mouse automatically detects the type of port to which it is connected and configures the mouse automatically. Serial-PS/2 hybrid mice usually come with a mini-DIN connector on the end of their cable and an adapter that converts the mini-DIN to a 9- or 25-pin serial port connector, although the reverse is sometimes true on early examples of these mice. PS/2-USB mice usually come with the USB connector on the end of their cable and include a mini-DIN (PS/2) adapter.

Sometimes people use adapters to try to connect a serial mouse to a motherboard mouse port or a motherboard mouse to a serial port. If this does not work, it is not the fault of the adapter. If the mouse does not explicitly state that it is both a serial and a PS/2-type mouse, it works only on the single interface for which it was designed. Most of the time, you find the designation for which type of mouse you have printed on its underside. A safe rule of thumb to follow is if the mouse didn't come with an adapter or came bundled with a system, it probably won't work with an adapter.

USB

The extremely flexible USB port is increasingly being used for mice as well as keyboards and other I/O devices. Compared to the other interfaces, USB mice (and other USB pointing devices such as trackballs) have the following advantages:

- *USB mice move much more smoothly than the traditional PS/2-type.* This is because the frequency with which the mouse reports its position is much higher. A typical PS/2 mouse has a reporting rate of about 40Hz, whereas an average USB mouse has a reporting rate of 125Hz. Several utilities are available to test and adjust the mouse frequency.
- *Mice with the most advanced features are sometimes made especially for the USB port.* One example is the Logitech iFeel mouse, the first mouse with an optical sensor plus force feedback. It vibrates gently as you move the mouse over clickable buttons on Web pages, software menus, and the Windows desktop, and it's made especially for USB.

- *USB mice and pointing devices, similar to all other USB devices, are hot-swappable*. If you like to use a trackball and your computing partners prefer mice, you can just lean over and unplug the other users' pointing device and plug in your own, or move it from PC to PC. You can't do that with the other port types.
- *USB mice can be attached to a USB hub, such as the hubs contained in some USB keyboards, as well as standalone hubs*. Using a hub makes attaching and removing your mouse easy without crawling around on the floor to reach the back of the computer.

Although the early USB mice were decidedly on the premium end of the price scale, you can buy decent USB mice for about the same cost as good-quality hybrid serial-PS/2 mice these days.

If you want to use a USB mouse at an MS-DOS prompt, in Windows safe mode, or in some other environment outside of normal Windows 98 or later, make sure that USB Legacy mode is enabled in your PC's BIOS, as discussed earlier in this chapter. Legacy mode enables non-USB-aware systems to recognize a USB keyboard and mouse.

A fourth type of connection, the bus mouse (referred to by Microsoft as the Inport mouse), used a dedicated adapter card and is now obsolete. For more information about the bus mouse, see Chapter 17 of *Upgrading and Repairing PCs, 11th Edition*, which is included on the DVD-ROM supplied with this book.

Mouse Troubleshooting

If you are experiencing problems with your mouse, you need to look in only two general places—hardware or software. Because mice are basically simple devices, looking at the hardware takes very little time. Detecting and correcting software problems can take a bit longer, however. To troubleshoot wireless mice, see "Troubleshooting Wireless Input Devices," later in this chapter.

Cleaning Your Mouse

If you notice that the mouse pointer moves across the screen in a jerky fashion, it might be time to clean your mouse. For a mouse with a roller-ball, this jerkiness is caused when dirt and dust become trapped around the mouse's ball-and-roller assembly, thereby restricting its free movement.

From a hardware perspective, the mouse is a simple device, so cleaning it is easy. The first step is to turn the mouse housing over so that you can see the ball on the bottom. Notice that surrounding the ball is an access panel you can open. Sometimes instructions indicate how the panel is to be opened. (Some off-brand mice might require you to remove some screws to get at the roller ball.) Remove the panel to see more of the roller ball and the socket in which it rests.

If you turn the mouse back over, the rubber roller ball should fall into your hand. Take a look at the ball. It might be gray or black, but it should have no visible dirt or other contamination. If it does, wash it in soapy water or a mild solvent, such as contact lens cleaner solution or alcohol, and dry it off.

Now take a look at the socket in which the roller ball normally rests. You will see two or three small wheels or bars against which the ball usually rolls. If you see dust or dirt on or around these wheels or bars, you need to clean them. The best way is to use a compressed air duster, which can blow out any dust or dirt. You also can use some electrical contact cleaner to clean the rollers. Remember, any remaining dirt or dust impedes the movement of the roller ball and results in the mouse not working as it should.

Put the mouse back together by inserting the roller ball into the socket and then securely attaching the cover panel. The mouse should look just as it did before you removed the panel, except that it will be noticeably cleaner.

One of the major advantages of the new breed of optical mice from Microsoft and Logitech is the lack of moving parts. Just wipe away dust from the optical sensor, and that's all the cleaning an optical mouse needs.

Interrupt Conflicts

Interrupts are internal signals used by your computer to indicate when something needs to happen. With a mouse, an interrupt is used whenever the mouse has information to send to the mouse driver. If a conflict occurs and the same interrupt used by the mouse is used by a different device, the mouse will not work properly—if at all.

Interrupt conflicts do not usually occur if your system uses a mouse port, but they can occur with the other types of mouse interfaces. Mouse ports built into modern motherboards are almost always set to IRQ12. If your system has a motherboard mouse port, be sure you don't set any other adapter cards to IRQ12; otherwise, a conflict will result. This does not apply to USB mice; it applies only to those connected to DIN or mini-DIN (PS/2) mouse ports.

When you are using a serial mouse, interrupt conflicts typically occur if you add third and fourth serial ports, using either an expansion card or internal serial device, such as a modem. This happens because in ISA bus systems, the odd-numbered serial ports (1 and 3) usually are configured to use the same interrupts as the even-numbered ports (2 and 4) are; IRQ4 is shared by default between COM1 and COM3, and IRQ 2 is shared by default between COM2 and COM4. Therefore, if your mouse is connected to COM2 and an internal modem uses COM4, they both might use the same interrupt, and you can't use them at the same time.

Because the mouse generates interrupts only when it is moved, you might find that the modem functions properly until you touch the mouse, at which point the modem is disconnected. Another example is when your system will run properly until you try to go online with your modem; then the conflict usually locks up the system. You might be able to use the mouse and modem at the same time by moving one of them to a different serial port. For instance, if your mouse uses COM1 and the modem still uses COM4, you can use them both simultaneously because odd and even ports use different interrupts.

The best way around these interrupt conflicts is to make sure no two devices use the same interrupt. Serial port adapters are available for adding COM3 and COM4 serial ports that do not share the interrupts used by COM1 and COM2. These boards enable the new COM ports to use other normally available interrupts, such as IRQs 10, 11, 12, 15, and 5. I never recommend configuring a system with shared ISA interrupts; it is a sure way to run into problems later. However, interrupts used by PCI boards can be shared if you use Windows 95 OSR 2.x, Windows 98, Windows Me, Windows 2000, or Windows XP with recent chipsets that support a feature called IRQ steering.

◀◀ See "PCI Interrupts," p. 328.

If you suspect an interrupt problem with a bus-type mouse, you can use the Device Manager built into Windows (which is accessible from the System control panel).

▶▶ See "Operating System Diagnostics," p. 1294.

The Device Manager in Windows (post 3.x) is part of the Plug-and-Play (PnP) software for the system, and it is usually 100% accurate on PnP hardware. Although some of these interrupt-reporting programs can have problems, most can easily identify the mouse IRQ if the mouse driver has been loaded. After the IRQ is identified, you might need to change the IRQ setting of the bus mouse adapter or one or more other devices in your system so that everything works together properly.

If your driver refuses to recognize the mouse at all, regardless of its type, try using a different mouse that you know works. Replacing a defective mouse with a known good one might be the only way to know whether the problem is indeed caused by a bad mouse.

I have had problems in which a bad mouse caused the system to lock right as the driver loaded or when third-party diagnostics were being run on the system. If you use a DOS-based diagnostic, such as Microsoft MSD or AMIDIAG, and the system locks up during the mouse test, you have found a problem with either the mouse or the mouse port. Try replacing the mouse to see whether that helps. If it does not, you might need to replace the serial port or bus mouse adapter. If a motherboard-based mouse port goes bad, you can replace the entire motherboard—which is usually expensive—or you can just disable the motherboard mouse port via jumpers or the system BIOS setup program and install a serial mouse instead. This method enables you to continue using the system without having to replace the motherboard. On systems with Windows 98/Me/2000/XP, you also can switch to a USB mouse, using USB ports on your motherboard or by installing a PCI-based USB card—provided your system has a USB port.

Note

To learn more about using the Microsoft MSD diagnostic program to test for mouse or mouse-port problems, see Chapters 17 and 25 of *Upgrading and Repairing PCs, 11th Edition*, which is included on the DVD-ROM packaged with this book.

Driver Software

To function properly, the mouse requires the installation of a device driver. In DOS, you must load the driver manually through your `CONFIG.SYS` or `AUTOEXEC.BAT` file, but the driver is automatically loaded in all versions of Windows. For maximum utility in both Windows and command-prompt sessions run under Windows, use the latest version of the manufacturer's mouse driver for the version of Windows you are using. You need to use a driver such as MOUSE.COM only if you are using a DOS application you run by booting the system directly to a DOS prompt in Windows 9x. Windows drivers support the use of the mouse in DOS applications running under Windows by default.

If you need to use a mouse driver when you boot to a command prompt in Windows 9x/Me/2000, the easiest way to enable the driver is to add it to your `CONFIG.SYS` or `AUTOEXEC.BAT` file; I recommend adding the driver that runs from a command prompt (often called MOUSE.COM) to your `AUTOEXEC.BAT` file. For example, if the mouse driver is installed in a folder called `\MOUSE` on your `C:` drive, add this line to your `AUTOEXEC.BAT` file:

```
C:\MOUSE\MOUSE.COM
```

This loads the DOS mouse driver into RAM when you boot the computer. One long-time problem with mouse drivers has been the amount of conventional memory (memory below 640KB) used by the mouse driver.

One of the biggest problems with the separate mouse driver is getting it loaded into an upper memory block (UMB) to free up conventional memory. The older Microsoft mouse drivers—versions 9.0 and earlier—require a large block of 40KB–56KB UMB to load; upon loading, they shrink down to less than 20KB. Even though they take only 20KB or less after loading, you still need a very large area to get them "in the door."

The best tip I can give you for these separate drivers is to use the newest drivers available from Microsoft or Logitech because they use less conventional memory than earlier versions. If you need just the MS-DOS mouse drivers, you can download version 11.00 or above from the Microsoft Web site. The IntelliPoint driver for 32-bit versions of Windows also includes MS-DOS driver support.

Logitech's MOUSE.EXE MS-DOS mouse driver also can be loaded into UMBs, and all current versions of MouseWare (6.43 and above) include the CLOAKING.EXE device driver to enable the Logitech mouse driver to be loaded into extended memory to save even more conventional/UMB space. See the `Readme.txt` file included in the Windows 3.1 folder of the MouseWare CD-ROM for details.

Keep in mind that you can use only serial or PS/2 port mice with MS-DOS; USB mice will not work. Also, all mice are treated as two-button mice by the MS-DOS drivers unless you install Logitech menu software to activate the middle button.

◀◀ See "Taking Advantage of Unused Upper Memory," p. 477.

After placing the proper driver load command in your `CONFIG.SYS` or `AUTOEXEC.BAT` file, reboot the system with the mouse connected and ensure the driver loads properly. If the proper command is in place and the driver is not loading, watch your video screen as your system boots. At some point, you should see a message from the mouse driver indicating that it is loaded. If you see a message indicating that the driver failed to load, you must determine why. For example, the driver might not be capable of loading because not enough memory is available. After you determine why the driver is not loading, you need to rectify the situation and make sure the driver loads.

DOS Application Software

If your mouse does not work with a specific piece of DOS application software, check the setup information or configuration section of the program. Be sure you indicated to the program (if necessary) that you are using a mouse. If it still does not work and the mouse works with other software you are using, contact the technical support department of the application software company.

Microsoft IntelliMouse/IBM Scrollpoint

Late in 1996, Microsoft introduced a new variation of its popular mouse, called the IntelliMouse. This device looks exactly like the standard Microsoft mouse except for a miniature gray wheel rising up between the two buttons. Since Microsoft introduced the first IntelliMouse, Logitech and most other vendors have introduced their own versions of scrolling mice. Even low-cost systems often bundle some form of scrolling mouse today to make Web site navigation and document scrolling easier.

The wheel has two main functions. The primary function is to act as a scrolling device, enabling you to scroll through documents or Web pages by manipulating the wheel with your index finger. The wheel also functions as a third mouse button when you press it.

Although three-button mice have been available for years from vendors such as Logitech, the scrolling function provided a real breakthrough. No longer do you have to move the mouse pointer to click the scrollbar on the right side of your screen or take your hand off the mouse to use the arrow keys on the keyboard. You just push or pull on the wheel. This is a major convenience, especially when browsing Web pages or working with word processing documents or spreadsheets. Also, unlike three-button mice from other vendors, the IntelliMouse's wheel-button doesn't seem to get in the way and you are less likely to click it by mistake. Although it took a while for software vendors to support the wheel, improvements in application software and Windows support allow today's wheel mice to be fully useful with almost any recent or current Windows program.

Each vendor's mouse driver software offers unique features to enhance the basic operation of the mouse. For example, Logitech's MouseWare 9.2 driver enables you to select many uses for all three mouse buttons (the scroll wheel is treated as a third mouse button), as well as provides various options for how to scroll with each wheel click (three lines, six lines, or one screen). Microsoft's IntelliMouse driver offers a feature called ClickLock, which allows you to drag items without holding down the primary mouse button. In addition, it offers a Universal Scroll feature that adds scrolling mouse support to applications that lack such support. To get the most from whatever scrolling or other advanced-feature mouse you have, be sure you periodically download and install new mouse drivers.

Instead of the wheel used by Microsoft and Logitech, IBM and other mouse vendors frequently use various types of buttons for scrolling. Some inexpensive mice use a rocker switch, but the most

elegant of the non-wheel alternatives is IBM's ScrollPoint Pro, which uses a pressure-sensitive scroll stick similar to the TrackPoint pointing device used on IBM's notebook computer and some PC keyboards made by IBM and Unicomp. The scrollpointer in the center of the mouse enables you to smoothly scroll through documents without having to lift your finger to roll the wheel, as you do on the Microsoft version, which makes it much easier and more convenient to use. Because no moving parts exist, the ScrollPoint is also more reliable.

Optical Mice

Many newer mice have dispensed with the rolling ball or other mechanical movement detection devices and instead use a purely optical detection mechanism. Optical mice are not really new, but older designs required that the sensor in the optical mouse be moved over a grid, which was usually set up in the form of a special mouse pad. The sensor needed to "see" the grid to detect movement. Newer optical mice do not need special grids or pads because their sensors are sensitive enough to pick up movement by observing virtually any surface pattern features. They do have a hard time on especially smooth or clear surfaces, but most desktops have color and texture the sensors can easily detect. By virtue of having no moving parts, optical mice last virtually indefinitely and almost never require maintenance. The optical mechanism is also virtually immune from sticking or skidding, which was commonplace with the mechanical ball types. Overall, optical mice feature the best movement detection mechanism on the market and are highly recommended.

TrackPoint II/III/IV

On October 20, 1992, IBM introduced a revolutionary new pointing device called TrackPoint II as an integrated feature of its new ThinkPad 700 and 700C computers. Often referred to as a *pointing stick device*, TrackPoint II and its successors consist primarily of a small rubber cap that appears on the keyboard right above the B key, between the G and H keys. This was the first significant new pointing device since the mouse had been invented nearly 30 years earlier!

This device occupies no space on a desk, does not have to be adjusted for left-handed or right-handed use, has no moving parts to fail or become dirty, and (most importantly) does not require you to move your hands from the home row to use it. This is an absolute boon for touch typists.

I was fortunate enough to meet the actual creator and designer of this device in early 1992 at the spring Comdex/Windows World in Chicago. He was in a small corner of the IBM booth showing off his custom-made keyboards with a small silicone rubber nub in the middle. In fact, the devices he had were hand-built prototypes installed in standard desktop keyboards, and he was there trying to get public reaction and feedback on his invention. I was invited to play with one of the keyboards, which was connected to a demonstration system. By pressing on the stick with my index finger, I could move the mouse pointer on the screen. The stick itself did not move, so it was not a joystick. Instead, it had a silicone rubber cap that was connected to pressure transducers that measured the amount of force my finger was applying and the direction of the force and moved the mouse pointer accordingly. The harder I pressed, the faster the pointer moved. After playing around with it for just a few minutes, the movements became automatic—almost as though I could just think about where I wanted the pointer to go.

The gentleman at the booth turned out to be Ted Selker, the primary inventor of the device. He and Joseph Rutledge created this integrated pointing device at the IBM T.J. Watson Research Center. When I asked him when such keyboards would become available, he could not answer. At the time, there were apparently no plans for production, and he was only trying to test user reaction to the device.

Just over six months later, IBM announced the ThinkPad 700, which included this revolutionary device—then called the TrackPoint II Integrated Pointing Device. Since the original version came out, enhanced versions with greater control and sensitivity, called the TrackPoint III and IV, have become available.

Note

The reason the device was called TrackPoint II is that IBM had previously been selling a convertible mouse/trackball device called the TrackPoint. No relationship exists between the original TrackPoint mouse/trackball, which has since been discontinued, and the TrackPoint II integrated device. Since the original TrackPoint II came out, improved versions known as TrackPoint III and TrackPoint IV have become available. In the interest of simplicity, I will refer to all the TrackPoint II, III, and successive devices as just *TrackPoint*.

In its final production form, the TrackPoint consists of a small, red, silicone rubber knob nestled between the G, H, and B keys on the keyboard. The primary and secondary mouse buttons are placed below the spacebar where you can easily reach them with your thumbs without taking your hands off the keyboard.

IBM studies conducted by Selker found that the act of removing your hand from the keyboard to reach for a mouse and replacing the hand on the keyboard takes approximately 1.75 seconds. If you type 60wpm, that can equal nearly two lost words per minute, not including the time lost while you regain your train of thought. Almost all this time can be saved each time you use TrackPoint to move the pointer or make a selection (click or double-click). The combination of the buttons and the positioning knob also enable you to perform drag-and-drop functions easily.

IBM's research also found that people can get up to 20% more work accomplished using the TrackPoint instead of a mouse, especially when the application involves a mix of typing and pointing activities, such as with word processing, spreadsheets, and other typical office applications. In usability tests with the TrackPoint III, IBM gave a group of desktop computer users a TrackPoint and a traditional mouse. After two weeks, 80% of the users had unplugged their mice and switched solely to the TrackPoint device. Selker is convinced (as am I) that the TrackPoint is the best pointing solution for both laptop and desktop systems.

Another feature of the TrackPoint is that a standard mouse can be connected to the system at the same time to enable dual-pointer use. This setup not only enables a single person to use both devices, but also enables two people to use the TrackPoint and the mouse simultaneously to move the pointer on the screen. The first pointing device that moves (thus issuing a system interrupt) takes precedence and retains control over the mouse pointer on the screen until it completes its movement action. The second pointing device is automatically locked out until the primary device is stationary. This enables the use of both devices and prevents each one from interfering with the other.

IBM has added various versions of the TrackPoint to its notebook computers, as well as to high-end keyboards sold under the IBM, Lexmark, and Unicomp names. Notebook computer makers, such as HP and Toshiba, also have licensed the TrackPoint device (Toshiba calls it Accupoint).

I have compared the TrackPoint device to other pointing devices for notebooks, such as the trackballs and even the capacitive touch pads, but nothing compares in terms of accuracy and control—and, of course, you don't have to take your hands off the keyboard!

Some notebook computer makers copied the TrackPoint instead of licensing it, but with poor results that include sluggish response to input and poor accuracy. One way of telling whether the TrackPoint device is licensed from IBM and uses the IBM technology is if it accepts IBM TrackPoint II/III/IV rubber caps. They have a square hole in them and will properly lock on to any of the licensed versions, such as those found in Toshiba systems.

IBM has upgraded its pointing stick to the TrackPoint III and the current TrackPoint IV. Two main differences exist in the III/IV system, but the most obvious one is in the rubber cap. The IBM TrackPoint II and Toshiba Accupoint caps are made from silicone rubber, which is grippy and works well in most

situations. However, if the user has greasy fingers, the textured surface of the rubber can absorb some of the grease and become slippery. Cleaning the cap (and the user's hands) solves the problem, but it can be annoying at times. The TrackPoint III/IV caps are made from a different type of rubber, which Selker calls "plastic sandpaper." This type of cap is much more grippy and does not require cleaning except for cosmetic purposes. I have used both types of caps and can say for certain that the TrackPoint III/IV cap is superior.

Note

Because the Accupoint device used in the Toshiba notebooks is licensed from IBM, it uses the same hardware (a pressure transducer called a *strain gauge*) and takes the same physical caps. I ordered a set of the new TrackPoint III caps and installed them on my Toshiba portable systems, which dramatically improved the grip. You can get these caps by ordering them from IBM Parts directly or from others who sell IBM parts, such as DakTech, under IBM part number 84G6536. The cost is approximately $5 for a set of two "plastic sandpaper" red caps.

Replacing the cap is easy—grab the existing cap with your fingers and pull straight up; it pops right off. Then, push on the new red IBM TrackPoint III/IV cap in its place. You will thank me when you feel how you can grip the new IBM cap much more easily than you can grip the designs used by others.

The other difference between the TrackPoint II and III/IV from IBM is in the control software. IBM added routines that implement a subtle technique Selker calls "negative inertia," which is marketed under the label *QuickStop response*. This software not only takes into account how far you push the pointer in any direction, but also how quickly you push or release it. Selker found that this improved software (and the sandpaper cap) enables people to make selections up to 8% faster.

TrackPoint IV includes an extra scroll button, as well as the ability to press the TrackPoint nub to select as if using the left mouse button. These new features make the TrackPoint even better to use.

The bottom line is that anyone who touch types should strongly consider only portable systems that include an IBM-licensed TrackPoint device (such as Toshiba). TrackPoints are far superior to other pointing devices, such as the touch pads, because the TrackPoint is faster to use (you don't have to take your hands off the keyboard's home row), easier to adapt to (especially for speedy touch typists), and far more precise. It takes some getting accustomed to, but the benefits are worth it.

The benefits of the TrackPoint are not limited to portable systems, however. If you use a notebook computer with TrackPoint like I do, you can have the same features on your desktop keyboard. For desktop systems, I use a Lexmark keyboard with the IBM-licensed TrackPoint device built in. This makes for a more consistent interface between desktop and notebook use because I can use the same pointing device in both environments. You also can buy these keyboards directly from Unicomp; IBM also offers TrackPoint IV in some of its high-end keyboards available at retail.

Mouse and Pointing Stick Alternatives

Because of Windows, many users spend at least as much time moving pointers around the screen as they do in typing, making pointing device choices very important. In addition to the mouse and the pointing stick choices discussed earlier in this chapter, several other popular pointing devices are available, including

- Track pads, such as the Cirque GlidePoint
- Trackballs from many vendors
- Upright mice, such as the 3M Renaissance Mouse

All these devices are treated as mice by the operating system but offer radically different options for the user in terms of comfort. If you're not satisfied with a regular mouse and don't want to use an integrated pointing stick such as the TrackPoint II/III/IV, look into these options.

GlidePoint/Touch Pad

Cirque originated the touch pad (also called a *track pad*) pointing device in 1994. Cirque refers to its technology as the GlidePoint and has licensed the technology to other vendors such as Alps Electric, which also uses the term Glidepoint for its touch pads. The GlidePoint uses a flat, square pad that senses finger position through body capacitance. This is similar to the capacitance-sensitive elevator button controls you sometimes encounter in office buildings or hotels.

When it is used on a portable computer's keyboard, the touch pad is mounted below the spacebar, and it detects pressure applied by your thumbs or fingers. Transducers under the pad convert finger movement into pointer movement. Several laptop and notebook manufacturers have licensed this technology from Cirque and have incorporated it into their portable systems. Touch pads are also integrated into a number of mid-range to high-end keyboards from many vendors. When used on a desktop keyboard, touch pads are often offset to the right side of the keyboard's typing area.

Touch pads feature mouse buttons, although the user also can tap or double-tap on the touch pad's surface to activate an onscreen button located under the touch pad's cursor. Dragging and dropping is accomplished without touching the touch pad's buttons; just move the cursor to the object to be dragged, press down on the pad, hold while moving the cursor to the drop point, and raise the finger to drop the object. Some recent models also feature additional hot buttons with functions similar to those on hot-button keyboards.

The primary use for touch pads has been for notebook computer– and desktop keyboard–integrated pointing devices, although Cirque and Alps have both sold standalone versions of the touch pad for use as a mouse alternative on desktop systems. Cirque's touch pads are now available at retail under the Fellowes brand name, as well as direct from the Cirque Web site.

Although it has gained wide acceptance, especially on portable computers, touch pad technology can have many drawbacks for some users. Operation of the device can be erratic, depending on skin resistance and moisture content. The biggest drawback is that to operate the touch pad, users must remove their hands from the home row on the keyboard, which dramatically slows their progress. In addition, the operation of the touch pad can be imprecise, depending on how pointy your finger or thumb is! On the other hand, if you're not a touch typist, removing your hands from the keyboard to operate the touch pad might be easier than using a TrackPoint. Even with their drawbacks, touch pad pointing devices are still vastly preferable to using a trackball or a cumbersome external mouse with portable systems.

Unless you want to use a "real" mouse with a portable system, I recommend you sit down with portable computers that have both touch pad and TrackPoint pointing devices. Try them yourself for typing, file management, and simple graphics and see which type of integrated pointing device you prefer. I know what I like, but you might have different tastes.

Trackballs

The first trackball I ever saw outside of an arcade was the Wico trackball, a perfect match for mid-1980s video games and computer games, such as Missile Command and others. It emulated the eight-position Atari 2600 analog joystick but was capable of much more flexibility.

Unlike the mid-80s trackballs, today's trackballs are used primarily for business instead of gaming. Most trackballs use a mouse-style positioning mechanism—the differences being that the trackball is on the top or side of the case and is much larger than a mouse ball. The user moves the trackball

rather than the input device case, but rollers or wheels inside most models translate the trackball's motion and move a cursor onscreen the same way that mouse rollers or wheels convert the mouse ball's motion into cursor movement.

Trackballs come in a variety of forms, including ergonomic models shaped to fit the (right) hand, ambidextrous models suitable for both lefties and right-handers, optical models that use the same optical sensors found in the latest mice in place of wheels and rollers, and multibutton monsters that look as if they're the result of an encounter with a remote control.

Because they are larger than mice, trackballs lend themselves well to the extra electronics and battery power needed for wireless use. Logitech offers several wireless trackball models that use radio-frequency transceivers; for details of how this technology works, see the section "Wireless Input Devices," later in this chapter.

Trackballs use the same drivers and connectors as conventional mice. For basic operations, the operating-system-supplied drivers will work, but you should use the latest version of the vendor-supplied drivers to achieve maximum performance with recent models.

Cleaning and Troubleshooting Trackballs

Trackball troubleshooting is similar to mouse troubleshooting. For issues other than cleaning the trackball, see the section "Mouse Troubleshooting," earlier in this chapter.

Because trackballs are moved by the user's hand rather than by rolling against a tabletop or desktop, they don't need to be cleaned as often as mouse mechanisms do. However, occasional cleaning is recommended, especially with trackballs that use roller movement-detection mechanisms. If the trackball pointer won't move, skips, or drags when you move the trackball, try cleaning the trackball mechanism.

Trackballs can be held into place by a retaining ring, an ejection tab, or simply by gravity. Check the vendor's Web site for detailed cleaning instructions if your trackball didn't come with such instructions. Swabs and isopropyl alcohol are typically used to clean the trackball and rollers or bearings; see the trackball's instructions for details.

3M's Renaissance Mouse/Upright Mouse

Many PC users who grew up using joysticks on the older video games experienced some "interface shock" when they turned in their joysticks for mice. And even long-time mouse users nursing sore arms and elbows have wondered whether the mouse was really as "ergonomic" as it is sometimes claims to be.

3M's solution, developed late in 2000, is to keep the traditional ball-type mouse positioning mechanism but change the user interface away from the hockey puck/soap bar design used for many years to a slanted handle that resembles a joystick (see Figure 18.12). 3M's Renaissance Mouse is available in two hand sizes and attaches to either the PS/2 port or USB port (serial ports are not supported). The single button on the top of the handle is a rocker switch; push on the left side to left-click and on the right side to right-click. The front handgrip provides scrolling support when the special Renaissance Mouse driver software is installed.

The Renaissance Mouse enables the user to hold the pointing device with a "handshake"-style hand and arm position. 3M's Web site provides detailed ergonomic information to encourage the proper use of the Renaissance Mouse, which comes with software to support scrolling and other advanced functions. Because the Renaissance Mouse is a major departure from traditional mouse designs, it features both a 30-day money-back return policy and a two-year warranty.

Figure 18.12 The 3M Renaissance Mouse combines an ergonomic shape with a standard mouse-movement mechanism.

Input Devices for Gaming

Originally, game players on the PC used the arrow keys or letter keys on the keyboard to play all types of games; I remember putting Larry Bird and Dr. J through their paces in the original version of Electronic Arts One-on-One basketball with an 84-key keyboard! As you can imagine, this limited the number and type of games that could be played on the PC.

Analog Joysticks and the Game Port

As video standards improved, making games more realistic, input devices made especially for game play also became more and more popular. The first joysticks made for the IBM PC were similar to joysticks made for its early rival, the Apple II series. Both the IBM and Apple II joysticks were analog devices that lacked much of the positive feedback game players were accustomed to from the Atari 2600, Commodore 64, or arcade joysticks. These joysticks also required frequent recalibration o work properly and were far from satisfactory to hardcore game players. Also, these devices required their own connector—the 15-pin game port. The game port found its way onto many sound cards as well as onto multi-I/O cards made for ISA and VL-Bus systems.

Even though joysticks began to add better features, including spring action, video game-style gamepads, and flight control options, the analog nature and slow speed of the gameport began to restrict performance as CPU speeds climbed above 200MHz and high-speed AGP and PCI video cards made ultra-realistic flying, driving, and fighting simulators possible.

A better gaming controller connector was badly needed, and USB again came to the rescue.

USB Ports for Gaming

The very versatile USB port has become the preferred connector for all types of gaming controllers, including joysticks, gamepads, and steering wheels. Instead of making a single inadequate joystick work for all types of games, users can now interchange controllers using the hot-swap benefits of USB and use the best controller for each type of game.

Although low-end game controllers now on the market can connect to either the venerable game port or the USB port, serious gamers want USB because of its higher speed, better support for force feedback (which shakes the game controller realistically to match the action onscreen), and tilting (tilt the gamepad and the onscreen action responds).

As with USB mice, your USB-connected gaming controllers are only as good as their software drivers. Be sure to install the latest software available to keep up with the latest games.

Compatibility Concerns

If you play a lot of older games designed in the heyday of the 15-pin gameport, consider keeping a gameport-type controller. Even though the vendors of USB game controllers strive to make the USB port emulate a game port for use with older games, some older games can't be fooled. If you have problems using a USB game controller with a specific game, check the game's Web site for patches, as well as your game controller's Web site for tips and workarounds.

Programmable Game Controllers

Some of the latest controllers are programmable, enabling you to develop profiles that provide you with features such as one-button operation of keyboard shortcuts or other game commands and adjustments to range of motion. To use these profiles, be sure you install the driver software supplied with your game controller and change to the profile you have customized for a particular program whenever you start that program.

Choosing the Best Game Controller

If you're a serious gamer who likes various types of games, you might need about as many game controllers as a golfer needs clubs. An increasing number of specialized controllers are on the market, and even familiar favorites like joysticks and steering wheels are available in new variations.

Table 18.4 provides a quick reference to the many types of game controllers available today for PCs.

Table 18.4 Game Controller Overview

Controller Type	Suitable For	Desirable Features	Sample Products
Joystick	Action games, including flight and shooting	Force feedback; program mable actions; rudder panels	Microsoft Sidewinder 2; Logitech WingMan Extreme Digital 3D; Thrustmaster Top Gun AfterBurner Joystick
Steering wheel	Driving games	Force feedback; programmable actions; foot pedals	Microsoft Precision Racing Wheel; LogitechWingMan Formula Force GP; Thrustmaster Force Feedback Racing Wheel-PC

Table 18.4 Continued

Controller Type	Suitable For	Desirable Features	Sample Products
Game pad	Driving and sports games	Force feedback; motion sensing; programmable buttons; and mouse keyboard emulation	Microsoft Sidewinder Thrustmaster Freestyle Pro; FireStorm Dual Power Gamepad; Logitech WingMan Rumblepad
Voice chat and control	Most multiplayer games	Voice communication with other players in a game (such as conferences with members of your team or taunting an opponent)	Microsoft Game Voice
Strategy controller	Strategy games	Programmable buttons; shortcuts; record actions as you play; can control camera movement in many 3D strategy titles	Microsoft Sidewinder Strategic Commander

Wireless Input Devices

For several years, many manufacturers have offered cordless versions of mice and keyboards. In most cases, these devices have used either infrared or short-range radio transceivers to attach to standard serial or PS/2 ports, with matching transceivers located in the mouse or keyboard. Wireless input devices are designed to be easier to use in cramped home-office environments and where a large-screen TV/monitor device is used for home entertainment and computing. Some game controllers are now available in wireless forms as well.

Radio Versus Infrared

Although some vendors still use infrared transceivers, most vendors support radio signals. Having used both types, I can tell you that a radio-frequency input device beats an infrared input device hands down for use at home or in a small one- or two-person office. Because infrared requires an unobstructed direct line between the transceivers, when I used an infrared keyboard/pointing stick combination at a client site, I was constantly re-aiming the keyboard at the receiver to avoid losing my signal. When I used a radio mouse, on the other hand, there were no line-of-sight issues to worry about. The only advantage to infrared is cost, but the problems of reliability in my mind outweigh any cost savings.

Major Vendors and Products

Unlike conventional mouse and keyboard producers, whose numbers are legion, the ranks of cordless input device makers are small. The major vendors include

- *Logitech.* Radio-frequency mice and keyboards
- *Microsoft.* Radio-frequency mice
- *Other vendors.* Infrared mice and keyboards (usually combination units)

Logitech

Mouse maker Logitech manufactures both radio-frequency wireless keyboards and radio-frequency wireless mice (first developed in 1992). Because Logitech developed wireless mice for several years before developing wireless keyboards, its older wireless mouse receivers work only with mice; you

must use a separate receiver for its wireless keyboards. If you want to use a wireless mouse and keyboard, you should purchase both units as a bundle; a single receiver with dual mouse and keyboard channels is usually supplied with bundled wireless keyboard/mouse sets. Check Logitech's support Web site for details about the compatibility of a particular receiver with a specified Logitech wireless mouse or keyboard.

Logitech's cordless series of wireless keyboard/mouse combinations can be attached through either the PS/2 mouse/keyboard ports or the USB port, allowing them to be used with older non-USB-aware versions of Windows as well as the newer versions (Windows 98 and later) that support USB. Older wireless mice used either the PS/2 port or the serial port.

Microsoft and Other Vendors

Microsoft makes a series of wireless input devices at this writing. Its Cordless Wheel Mouse uses a receiver that can attach to either a PS/2 mouse port or a serial port, and its Wireless IntelliMouse requires a USB port.

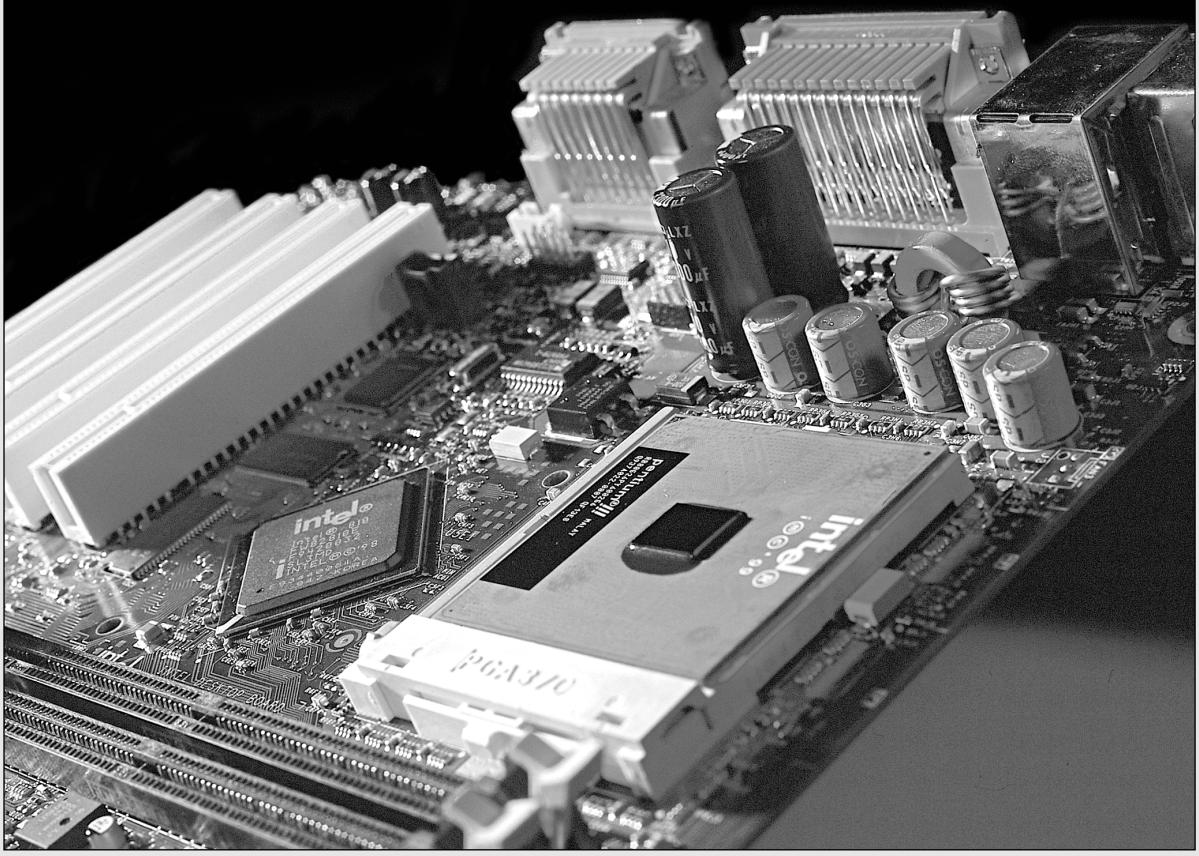
Infrared input devices usually combine both keyboard and mouse functions. These devices are offered by vendors such as Acer, PC Concepts, SIIG, and others and typically attach to the PS/2 mouse and keyboard ports. For improved reliability, some feature dual infrared transceivers in the keyboard or receiving unit to enable the unit to be moved around without losing the signal. Some infrared models were designed with a long signal range for use in computer presentations, but most of these have since been redesigned to use radio-frequency technology.

Wireless Pointing Device Issues

Before you invest in wireless pointing devices for multiple computers, you should be aware of the following issues:

- *Line-of-site issues.* Infrared devices won't work if the IR beam between the pointing device and the receiver attached to the system is blocked. These units are not as suitable for casual in-the-lap use as radio-frequency units are.
- *Radio-frequency interference.* Although early wireless mice used analog tuners that were hard to synchronize, today's wireless input devices typically use digital selectors. However, if several similar devices are used in close quarters, a receiver might actually receive data from the wrong mouse or keyboard. Also, metal desks and furniture can reduce range and cause erratic cursor movement. Most wireless devices operate around 27MHz, minimizing interference from devices such as cordless phones. Check with the vendor for tips on overcoming interference issues.
- *Battery life and availability.* Early wireless devices sometimes used unusual, expensive batteries. Today's units run on common battery types, such as AAA. Battery life is usually rated at about six months. Be sure you have spare batteries for the input device to avoid failures due to running out of battery power. The included software by companies such as Logitech gives users an onscreen warning when batteries run low. Furthermore, when using an optical wireless mouse, you should try working on brighter or whiter surfaces. Many optical mice adjust their sensors based on the illumination of the surface, which is why you might see the light in the mouse change intensity. The less intense the internal LED operates, the less battery power being used.
- *Location.* The range of wireless devices can vary from 6 feet to as much as 30 feet. Consider where the device will be used before making your purchase. For instance, in an office where multiple devices might be used at the same time, a close-range device might be more desirable to avoid cross talk among devices. On the other hand, the home user who wants to sit away from the screen while maintaining control might want an extended range.

- *User experience.* Different users will have different expectations of wireless input devices, but in general, the more a wireless input device acts like its wired siblings, the better. The fact that a device is wireless should not compromise its functionality. If things such as reliability, connection, or driver problems hinder proper usage, the device isn't worth using. Hardcore gamers who need the fastest response time possible generally favor the responsiveness of a wired optical mouse over any wireless mouse. Although minimal, some lag time does exist. Some mice can require up to 0.25 centimeter of movement before responding. This lag time can also affect users doing graphical work requiring the superior consistency and accuracy of a wired optical mouse.



Troubleshooting Wireless Input Devices

If your wireless input device does not work, check the following:

- *Battery failure.* The transceivers attached to the computer are powered by the computer, but the input devices themselves are battery-powered. Check the battery life suggestions published by the vendor; if your unit isn't running as long as it should, try using a better brand of battery or turning off the device if possible.
- *Lost synchronization between device and transceiver.* Both the device and the transceiver must be using the same frequency to communicate. Depending on the device, you might be able to resynchronize the device and transceiver by pressing a button, or you might need to remove the battery, reinsert the battery, and wait for several minutes to reestablish contact.
- *Interference between units.* Check the transmission range of the transceivers in your wireless units and visit the manufacturer's Web site for details on how to reduce interference. Typically, you should use different frequencies for wireless devices on adjacent computers.
- *Blocked line of sight.* If you are using infrared wireless devices, check the line of sight carefully at the computer, the space between your device and the computer, and the device itself. You might be dangling a finger or two over the infrared eye and cutting off the signal—the equivalent of putting your finger over the lens on a camera.
- *Serial port IRQ conflicts.* If the wireless mouse is connected to a serial port and it stops working after you install another add-on card, check for conflicts using the Windows Device Manager.
- *Disconnected transceiver.* If you have moved the computer around, you might have disconnected the transceiver from its keyboard, PS/2 mouse, serial, or USB port. You can plug a USB device in without shutting down the system, but the other types require you to shut down, reattach the cable, and restart to work correctly.
- *USB Legacy support not enabled.* If your wireless device uses a transceiver connected to the USB port and the device works in Windows, but not at a command prompt, make sure you have enabled USB Legacy support in the BIOS.

CHAPTER 19

Internet Connectivity

Relating Internet and LAN Connectivity

Communication between computers is a major part of the PC computing industry. Thanks to the World Wide Web (WWW), no computer user is an island. Whether using a modem or broadband technology, virtually all PCs can be connected to other computers, enabling them to share files, send and receive email, and access the Internet. This chapter explores the various technologies you can use to expand the reach of your PC around the block and around the world.

It might surprise you to see discussions of protocols and networking setup in both this chapter and the LAN chapter of this book, but a modem connection is really just another form of networking. In fact, 32-bit versions of Windows from Windows NT and Windows 9x all the way through Windows XP have all but blended the two services into a single entity.

The reason for this combination is that the typical target for a modem connection has changed over the years. Computer users a decade ago dialed in to *bulletin board systems (BBSes)*, which are proprietary services that provide terminal access to other computers. However, BBSes are practically extinct today. Similarly, proprietary online services such as America Online and CompuServe, which have also been around for many years, have dropped their proprietary client software and protocols and have been reborn as gateways to the Internet.

With the explosive growth of the Internet, modem and network technologies were joined because both could use the same client software and protocols. Today, the most popular suite of networking protocols—TCP/IP—is used on both LANs and the Internet. When you dial in to an Internet service provider (ISP), you are actually connecting to a network using a modem instead of a network interface card, and when you use most broadband services, your path to the Internet typically starts with a network interface card.

Although most new PCs still include an analog modem, an increasing number of PC users are abandoning analog modem Internet access for the faster world of broadband access. As of June 2001, for example, there were an estimated 9.3 million subscribers to residential broadband Internet services such as DSL and cable modems in the U.S. and Canada. About 6.4 million of these broadband subscribers had selected cable modem service, compared to just 2 million as of February 2000. Some DSL and cable modem service providers have had a rough time financially in 2001 and early 2002, but broadband Internet is an increasingly popular choice for both experienced computer users and novices. Broadband subscribers have been increasing by at least 14% per quarter every quarter since early 2000. Plus, a recent survey suggests that as many as one-third of current dial-up users plan to switch to broadband Internet access within a year.

Because broadband Internet is the fastest-growing part of Internet access and because it is completely different from the familiar analog modem environment many computer users have grown up with, broadband Internet devices are covered first in this chapter. Analog modems, however, still have their uses and a large user base. Travelers, those without broadband options, or those on a budget still need an analog modem. Also, additional analog modems are required for some types of broadband service, and sometimes as a backup Internet access source. You'll find analog modem coverage in the second portion of the chapter.

Comparing Broadband and Analog Modem Internet Access

Even though most new PCs purchased at retail include some type of analog modem you can use for Internet and email access, you are likely to find that Internet and email access with an analog modem aren't sufficient for your needs if you use these services for more than a few minutes each day. Here are some reasons you should consider switching to a broadband service:

- *Speed.* The fastest analog modems can download data at a maximum rate of 56Kbps (limited in the U.S. to just 53Kbps by the FCC), whereas broadband services start at 128Kbps for ISDN and often exceed 500Kbps. Similarly, broadband services can upload data at several times the speed of an analog modem.
- *Convenience.* Cable modems and some types of DSL and satellite broadband Internet service are always on, providing you with an immediate connection as soon as you open your Web browser or email client. Analog modems require you to dial up the server and wait up to a minute before you can check your email or surf the Web. Similarly, always-on broadband services can provide you with immediate notification of incoming email, whereas analog systems can check for incoming email only if you stay online and tie up your phone line.
- *Telephone line usage.* In the wake of the September 11th terrorist attacks on the United States, keeping telephone communications lines open for emergencies has been a major consideration for many people. Most analog modems do not support call waiting, making it difficult for callers to reach you with important messages while you're online unless you use call-forwarding software. By contrast, most broadband services keep your telephone line free so you can check email or surf the Web and use the telephone at the same time.
- *Price.* One disadvantage of broadband communications is apparent when you see your bill: It costs two to three times as much per month as dial-up access with an analog modem. However, millions of U.S. users believe the additional speed and convenience of broadband make the extra cost of the service per month a worthwhile investment. If you use the Internet enough to justify installing a second phone line just for Internet use, the price gap narrows considerably because you can use most broadband services without tying up your single existing phone line.
- *Ease of reconnection after an operating system upgrade.* Because broadband Internet is usually based on automatically configured TCP/IP network settings, you should be able to keep your broadband connection running during a Windows upgrade with little difficulty. Just verify that you have the correct drivers for your Ethernet adapter (used for most broadband connections) before you perform the upgrade, note your computer and workgroup name, and you should be able to go online as soon as the upgrade is completed. A dial-up connection is often much tougher to keep working, especially because of the different methods used by various Windows versions for handling dial-up networking.

Broadband Internet Access Types

Thanks to the combination of huge multimegabyte downloads needed to update software and support hardware, dynamic Web sites with music and full-motion video, and increased demand for online services, even the fastest analog modem (which can download at just 53Kbps) isn't sufficient for heavy Internet use. More and more users are taking advantage of various types of broadband Internet access solutions, including

- Cable modem
- DSL
- Fixed-base wireless
- Satellite-based services
- ISDN
- Leased lines

At least one of these services might be available to you, and if you live in a large to medium-size city, you might be able to choose from two or more of these broadband solutions. The first portion of this chapter focuses on these solutions.

Note

For more information about broadband Internet access service types, installation, configuration, and troubleshooting, see *The Complete Idiot's Guide to High-Speed Internet Access* by Mark Edward Soper, published by Alpha Books (ISBN 0-7897-2479-0).

High Speed = Less Freedom

Although high-speed services such as cable modems, DSL, and others all represent major improvements in speed over existing dial-up analog or 56Kbps connections, one big drawback you should consider is the loss of freedom in choosing an ISP.

With an analog or a 56Kbps modem, you can choose from a wide variety of services, including

- Local ISPs (personalized service)
- National ISPs with dial-up access across the country (great for travelers)
- Online services with customized content plus Web access (AOL and CompuServe)
- Family-friendly filtered Internet access (Mayberry USA and Lightdog)
- Business-oriented Web hosting plus Internet access plans from many vendors

At present, if you want faster speed, you must use the ISP provided with your high-speed service. Whether it's your local telephone company, a third-party vendor, or your friendly cable TV operator, their ISP is your ISP. When you evaluate a high-speed service, remember to look at the special features and services provided by the ISP and its track record for reliability and keeping customers happy. After all, the quality of the work your ISP does is reflected in the quality of your broadband connection.

Tip

If you want the extra speed and convenience of broadband Internet but want to shield your family from some types of Internet content, several filtering services are available that work with your preferred broadband service, including these:

- Cleanweb's Filter Your Internet (FYI) at `www.cleanweb.net/fyi`
- FamilyConnect Filter Pack at `www.familyconnect.com/`
- FamilyClick at `www.familyclick.com`

Cable Modems and CATV Networks

For many users, cable modem service—which piggybacks on the same cable TV (CATV) service lines that bring your TV many channels—represents both a big boost in speed from that available with ISDN and a major savings in initial costs and monthly charges. Unlike ISDN, cable modem service normally is sold as an "all you can eat" unlimited-access plan with a modest installation charge (often waived) and a small monthly fee for the rental of the cable modem. Some cable modem providers now provide a low-cost (around $30) self-install kit for their existing cable TV customers, enabling customers to attach cable modems to their computers' USB ports or network cards. Because more and more cable networks support a single standard, you can also choose to buy your cable modem from any of several vendors in some cases, saving even more money over the long term.

Connecting to the Internet with a "Cable Modem"

As with ISDN, the device used to connect a PC to a CATV network is somewhat inaccurately called a modem. In fact, the so-called "cable modem" (a name I will continue to use, for the sake of

convenience) is actually a great deal more. The device does indeed modulate and demodulate, but it also functions as a tuner, a network bridge, an encryptor, an SNMP agent, and a hub. To connect your PC to a CATV network, you do not use a serial port as with standard modem technologies or ISDN terminal adapters. Instead, the most typical connection used today requires that you install a standard 10BASE-T or 10/100 Ethernet network interface adapter into a bus slot. The Ethernet adapter connects to the cable modem with a crossover cable that uses the standard RJ-45 connector but has wires reversed at one end. In fact, your PC and the cable modem actually form a two-node LAN, with the modem functioning as a hub. Some older cable modem services use an internal adapter for one-way service (using the conventional modem for uploads; this type of service is also called telco return), but the most common alternative to the Ethernet card is an external USB-based cable modem connection for two-way service.

Tip

For maximum speed and ease of sharing, I recommend that you connect your cable modem to a 10/100 Ethernet card or port or use a USB 2.0 port (built into many new machines or available as an add-on card for older systems). USB 1.1 ports limit the throughput of your cable modem.

The Cable Modem and the CATV Network

The cable modem connects to the CATV network using the same coaxial cable connection as your cable TV service (see Figure 19.1). Thus, the cable modem functions as a bridge between the tiny twisted-pair network in your home and the hybrid fiber/coax (HFC) network that connects all the cable customers in your neighborhood.

A few cable modem CATV systems have been built using the older one-way (download-only) coax cable, but this type of cable is much slower for cable modem use and is obsolete for both CATV and data communications. The industry has largely replaced coax with HFC. Before you sign up for CATV Internet service, find out which type of service is being offered. Only the two-way, HFC-based systems allow you to use the Internet independently of the telephone system; one-way cable modem service requires an analog modem for uploading page requests, files, and email. The modem can be built into your one-way cable modem (these are called *bundled* cable modems) or be a separate external analog modem. In either case, going online with a one-way cable modem ties up your phone line.

Digital CATV service, which brings your TV many more channels and a clearer picture, requires the cable TV provider to upgrade to an HFC physical plant. Thus, digital CATV service is a precursor to two-way cable modem service; pure-coax CATV systems can't be used to transmit digital service or handle two-way cable modem traffic. CATV systems that have been upgraded to digital service are capable of providing two-way cable modem service, after suitable head-end equipment is installed at the CATV central office. A good rule of thumb, therefore, is that CATV systems that don't offer digital cable TV might offer only one-way cable modem service or no cable modem service at all. A typical two-way cable modem connection is shown in Figure 19.1.

Originally, cable modems were not sold to users of CATV Internet access but were leased by the CATV companies offering Internet access to their cable modem customers. This is because each cable modem on a particular CATV network had to match the proprietary technology used by the network. In late 1998, DOCSIS-compliant cable modems began to be used by some CATV companies. DOCSIS refers to devices that meet the Data Over Cable Service Interface Specification standards established by Cable Television Laboratories, Inc. (CableLabs). Modems that meet DOCSIS standards are now referred to as CableLabs Certified cable modems. Visit the CableLabs Web site at `www.cablelabs.org` for a complete list of cable modems that are CableLabs Certified.

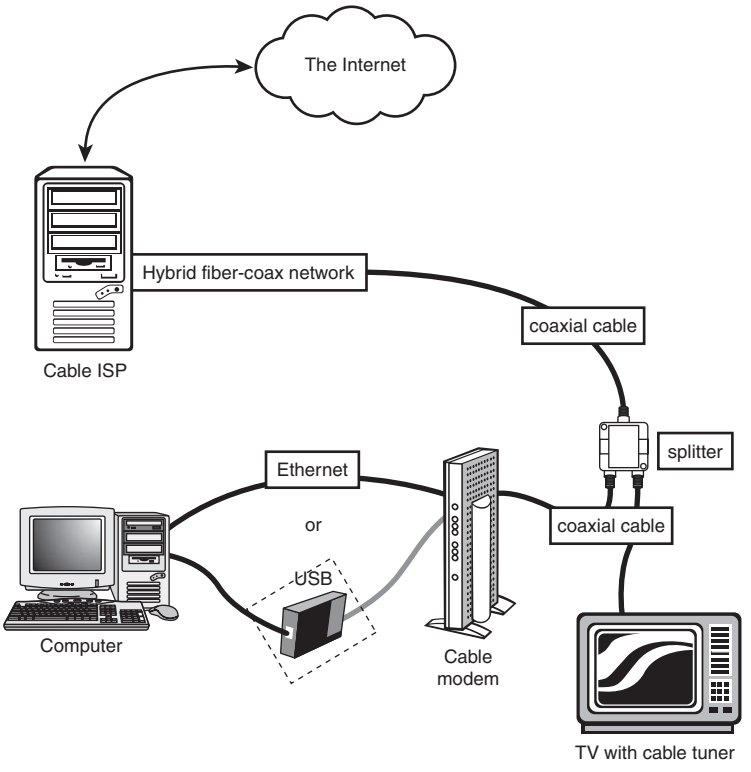


Figure 19.1 A typical hybrid fiber-coax cable TV network that also includes two-way cable modem service.

Many vendors of traditional modems and other types of communications products, such as Zoom Telephonics, 3Com, GVC, General Instruments, Philips, Motorola, Cabletron, and many others, now make CableLabs Certified Cable Modem-compliant hardware. However, because two versions of the CableLabs (DOCSIS) standard (1.0 and 1.1) exist, which can prevent free interchange of cable modems between networks, and the relatively high purchase cost of the cable modem ($125–$150 versus under $50 for an analog modem), some CATV Internet providers still require you to lease their own cable modems.

If you plan to keep cable modem service for more than a year, I recommend purchasing a CableLabs Certified cable modem, but if you're unsure of your long-term plans, leasing isn't all that expensive. Typical lease costs for the device add only about $10/month to the monthly rate of $30–$40 for cable modem service.

Types of Cable Modems

Cable modems come in several forms:

- *External cable modem "box."* It requires a 10BASE-T or 10/100 Ethernet NIC or a USB port. Some vendors provide "bundles" that combine the external cable modem with the NIC at a lower price than leasing or purchasing both separately. This type of cable modem is designed for fast uploads as well as fast downloads and works only on newer "two-way" CATV Internet connections. Almost all cable modems sold by retailers fall into this category.

- *Internal cable modem with a 56Kbps analog modem built in.* This type of cable modem provides fast downloads but uploads at analog speeds only; this type might use either an ISA or a PCI slot.
- *Internal cable modem for use with a separate 56Kbps analog modem.* This type might use either an ISA or a PCI slot. As with the previous model, uploads are at analog speeds only.
- *Internal cable modem for use with two-way service.* This type of cable modem is rare, but because some internal cable modems are now CableLabs Certified, you might see some cable ISPs offer these. Some also might be designed for one-way service, enabling the cable ISP to install a single modem for use with both types of service.
- *External cable modem with a 56Kbps analog modem built in.* This type of cable modem is sometimes designed to work with both one-way and two-way services.

Cable modem models that must be used with (or include) an analog modem are designed for older "one-way" CATV Internet connections; these will tie up your phone line when transmitting page requests as well as when sending uploads.

Note

For more comprehensive coverage of cable modem service types, installation, sharing, security, and use, see the *Absolute Beginner's Guide to Cable Internet Connections* by Mark Edward Soper (published by Que, 2002).

CATV Bandwidth

Cable TV uses what is known as a *broadband network*, meaning the bandwidth of the connection is split to simultaneously carry many signals at different frequencies. These signals correspond to the channels you see on your TV. A typical HFC network provides approximately 750MHz of bandwidth, and each channel requires 6MHz. Therefore, because the television channels start at about 50MHz, you would find channel 2 in the 50MHz–56MHz range, channel 3 at 57MHz–63MHz, and so on up the frequency spectrum. At this rate, an HFC network can support about 110 channels.

For data networking purposes, cable systems typically allocate one channel's worth of bandwidth in the 50MHz–750MHz range for downstream traffic—that is, traffic coming into the cable modem from the CATV network. In this way, the cable modem functions as a tuner, just like your cable TV box, ensuring that your PC receives signals from the correct frequency.

Upstream traffic (data sent from your PC to the network) uses a different channel. Cable TV systems commonly reserve the bandwidth from 5MHz to 42MHz for upstream signals of various types (such as those generated by cable TV boxes that enable you to order pay-per-view programming). Depending on the bandwidth available, you might find that your CATV provider does not furnish the same high speed upstream as it does downstream. This is called an *asymmetrical network*.

Note

Because the upstream speed often does not match the downstream speed (and to minimize noise, which tends to accumulate because of the tree-and-branch nature of the network), cable TV connections usually are not practical for hosting Web servers and other Internet services. This is largely deliberate because most CATV providers are currently targeting their traditional home user market. As the technology matures, however, this type of Internet connection is likely to spread to the business world as well. There are now specialized domain name services that can be used to "point" Web surfers to your cable modem or DSL connection.

Some cable ISPs require you to switch to a more expensive business plan if you want to host a server (including a P2P server such as Gnutella) on your cable modem connection. In fact, hosting a server on a residential cable modem service could be a violation of your contract and could lead to cancellation of your service.

The amount of data throughput that the single 6MHz downstream channel can support depends on the type of modulation used at the head end (that is, the system to which your PC connects over the network). Using a technology called 64 QAM (quadrature amplitude modulation), the channel might be capable of carrying up to 27Mbps of downstream data. A variant called 256 QAM can boost this to 36Mbps.

You must realize, however, that you will not achieve anything even approaching this throughput on your PC. First of all, if you are using a 10BASE-T Ethernet adapter to connect to the cable modem, you are limited to 10Mbps, but even this is well beyond the real-life results you will achieve. As with any LAN, you are sharing the available bandwidth with other users in your neighborhood. All your neighbors who also subscribe to the service use the same 6MHz channel. As more users are added, more systems are contending for the same bandwidth, and throughput goes down.

In November 1999, ZDTV tested five brands of cable modems in typical operations and found that the overhead of CATV proved to be a major slowdown factor. The cable modems were first connected directly to the server to provide a baseline for comparisons. Some of these tests showed speeds as high as 4Mbps. However, when the CATV cable was connected and the same tests were run, the best performer dropped to just 1.1Mbps, with others running even slower.

Tip

You can improve the performance of your cable modem or other broadband Internet access device by making changes to your system Registry that affect the size of the TCP receive window and other settings. I recommend the system tweaks available at the SpeedGuide.net Web site (`www.speedguide.net`). You can find tweaks for all Windows versions from Windows 95 through Windows XP, along with instructions on how to make the changes manually and easy methods for setting your system's Registry back to its default values.

Widespread reports from cable modem users across the country indicate that rush hour–type conditions occur at certain times of the day on some systems, with big slowdowns. This rush hour is due to increasing use of cable modem systems in the late afternoon and early evening, as daytime workers get home and pull up the day's news, weather, stocks, and sports on their Internet connections. Because cable modems are shared access, this type of slowdown is inevitable and becomes exceptionally severe if the CATV Internet provider doesn't use a fast enough connection to the rest of the Internet. To minimize this problem, many CATV Internet providers use caching servers at their point of presence connections to the Internet. These servers store frequently accessed Web pages to enable users to view pages without the delays in retrieving them from the original Web sites. By adding multiple T1 or T3 connections to the Internet backbones and using caching servers, ISPs can minimize delays during peak usage hours.

CATV Performance

The fact that you are sharing the CATV network with other users doesn't mean the performance of a cable modem isn't usually spectacular. Although the CATV network takes a big cut out of the maximum speeds, you'll still realize a throughput that hovers around 512Kbps, almost 10 times that of the fastest modem connection and four times that of ISDN. You will find the Web to be an entirely new experience at this speed. Those huge audio and video clips you avoided in the past now download in seconds, and you will soon fill your hard drives with all the free software available.

Add to this the fact that the service is typically quite reasonably priced. Remember that the CATV provider is replacing both the telephone company (if you have two-way service) and your ISP in your Internet access solution. The price can be about $40–$50 per month (including cable modem rental), which is twice that of a normal dial-up ISP account, but it is far less than ISDN, does not require a

telephone line (if your provider has two-way service), and provides 24-hour access to the Internet. The only drawback is that the service might not be available yet in your area. In my opinion, this technology exceeds all the other Internet access solutions available today in speed, economy, convenience, and widespread availability. Its nearest rival is DSL, which is still not as widely available geographically and is plagued with poor coordination between ISPs and telephone companies. Because cable modem Internet service providers provide the physical plant, provide ISP services, and can provide equipment, you can get service installed in just days and avoid the finger-pointing common with other types of broadband Internet service.

CATV Internet Connection Security

Because your PC is sharing a network with other users in your neighborhood and because the traffic is bidirectional on systems using two-way cable modems, the security of your PC and the network becomes an issue. In most cases, some form of encryption is involved to prevent unauthorized access to the network. As with your cable TV box, the cable modem might contain encryption circuitry necessary to access the network. Your CATV provider might also supply encryption software that uses a special protocol to log you on to the network. This protects the CATV provider from non-paying users, but it doesn't protect you. The security features vary according to which cable modem is used; the popular CableLabs Certified standard for cable modems features built-in encryption.

If you use an operating system such as 32-bit Windows that has built-in peer networking capabilities, you might be able to see your neighbors' computers on the network if your provider doesn't use CableLabs Certified cable modems or some other form of encryption. The operating system has settings that enable you to specify whether other network users can access your drives. If these settings are configured improperly, your neighbors might be able to view, access, and even delete the files on your hard drives. Be sure the technician from the cable company installing the service addresses this problem. If you want to use a cable modem along with sharing access on your computer (for printing, file storage, and so on), I'd recommend that you use passwords for any shared drives, but you're even safer if you disable file and printer sharing on the system you connect to the cable modem.

▶▶ For more information on securing any type of Internet access, see "Securing Your Internet Connection," p. 1071.

Digital Subscriber Line

The biggest rival to the cable modem in the broadband Internet business is the digital subscriber line (DSL). DSL, like its predecessor ISDN, appeals to the telephone companies who might be able to use the existing POTS analog wiring to provide high-speed Internet access. Not every type of DSL is suitable for existing wiring; however, all but the fastest, most expensive types can sometimes be used with the existing POTS plant. DSL is also appealing to businesses that don't have access to cable modems but are looking for a high-performance, lower-cost alternative to the expensive ISDN services that top out at 128Kbps.

Note

Some technical discussions of DSL refer to xDSL. The *x* stands for the various versions of DSL being proposed and offered by local telephone companies and ISPs. DSL generally is used to refer to any type of digital subscriber line service.

One advantage of DSL compared to its most popular rival—cable modems—is that cable modems share common bandwidth, which means that a lot of simultaneous use by your neighbors can slow down your connection. If you use DSL you don't have this concern; whatever bandwidth speed you pay for is yours—period.

How DSL Works

DSL takes advantage of the broadband nature of the telephone system, using the system's capability to carry signals at multiple frequencies to allow both high-speed Internet traffic and phone calls at the same time. Two methods for sending and receiving signals are used by the most common type of DSL, Asymmetric DSL (ADSL):

- Carrierless Amplitude/Phase (CAP)
- Discrete Multitone (DMT)

Most early DSL installations used CAP, which splits the telephone line into three frequency bands. Exact frequency usage varies by system, but most typically, the divisions resemble the following:

- Voice calls use frequencies from 30Hz to 4KHz. This frequency is also used by answering machines, fax machines, and alarm systems.
- Upstream data such as Web page requests and sent email uses frequencies between 25Hz and 160Hz.
- Downstream data such as received Web pages and email uses frequencies between 240KHz and 1.5MHz.

Some systems use the 300Hz–700Hz range for downstream data and frequencies of 1MHz and above for upstream data.

Because voice, downstream, and upstream data use different frequencies, you can talk, surf, and send email at the same time.

DMT, the system used by most recent ADSL installations, divides the telephone line into 247 channels that are 4KHz wide. If a particular channel has problems, a different channel with better signal quality is used automatically. Unlike CAP, DMT uses some channels starting at around 8KHz to send and receive information.

Both types of signaling can have problems with interference from telephones and similar devices, so devices called *low-pass filters* are used to prevent telephone signals from interfering with signals above the 4KHz range, where DSL signals begin. The location of these filters depends on the type of DSL you use and whether you are installing DSL service yourself.

At the central switch, DSL data is transferred to a device called a *DSL access multiplexer (DSLAM)*, which transfers outgoing signals to the Internet and sends incoming signals to the correct DSL *transceiver* (the correct name for the so-called "DSL modem" that connects to your computer).

Who Can Use DSL—and Who Can't

DSL services are slowly rolling out across the country, first to major cities and then to smaller cities and towns. As with 56Kbps modems, rural and small-town users are probably out of luck and should consider satellite-based or fixed wireless Internet services where available for a faster-than-56Kbps experience.

Just as distance to a telephone company's central switch (CS) is an important consideration for people purchasing an ISDN connection, distance also affects who can use DSL in the markets offering it. For example, most DSL service types require that you be within about 18,000 feet (about 3 miles) wire distance to a telco offering DSL; some won't offer it if you're beyond 15,000 feet wire distance because the speed drops significantly at longer distances. Repeaters or a local loop that has been extended by the telco with fiber-optic line might provide longer distances. The speed of your DSL connection varies with distance: The closer you are to the telco, the faster your DSL access is. Many telcos that

offer some type of DSL service provide Web sites that help you determine whether, and what type of, DSL is available to you.

If you want to locate DSL service providers in your area, compare rates, and see reviews from users of the hundreds of ISPs now providing DSL service, set your browser to `http://www.dslreports.com`. The site provides a verdict on many of the ISPs reviewed, summarizing users' experiences and ranking each ISP in six categories.

Note

If you want to connect DSL to your SOHO or office LAN, check first to see what the provider's attitude is. Some users report good cooperation, whereas others indicate they were told "we can't help you" or were told that DSL "couldn't be connected to a LAN." Again, check around for the best policies. Low-cost switch/router combinations from companies such as Linksys and D-Link and Microsoft's Internet Connection Sharing provide relatively easy ways to share both DSL and other types of high-speed connections.

For "field-tested" DSL information (written originally for Pacific Bell DSL users but useful for everyone), check out `http://home.pacbell.net/golemite/`.

Even if your telco's central switch is well within wire distance range of your location, that's no guarantee that you qualify for DSL service. The design and condition of the wiring plant connecting your location with the central switch can prevent you from qualifying for DSL service. Because DSL service depends on successful sending and receiving of high-frequency data, a telephone wiring plant that blocks high-frequency signals can't be used for DSL service. Some of the typical issues with telephone lines that aren't DSL-friendly include

- *Loading coils*. These amplifiers boost voice signals and are sometimes called voice coils. Unfortunately, these block the high-frequency signals needed by DSL service.
- *Bridge taps*. Used to extend service to new customers without running separate lines all the way back to the central switch. Bridge taps can create a circuit that's too long for DSL service.
- *Fiber-optic cables*. Used to carry a lot of signals in a small physical space, fiber-optic cables use analog-to-digital (A/D) and digital-to-analog (D/A) converters where they connect to copper telephone lines. A/D and D/A converters can't pass DSL signals through to their destinations.

Major Types of DSL

Although the term *DSL* is used in advertising and popular discussions to refer to any form of DSL, many, many variations of DSL are used in different markets and for different situations. This section discusses the most common forms of DSL and provides a table that compares the various types of DSL service. Although many types of DSL service exist, you can choose only from the service types offered by your DSL provider:

- *ADSL (Asymmetrical DSL)*. The type of DSL used most often, especially in residential installations. Asymmetrical means that downstream (download) speeds are much faster than upstream (upload) speeds. For most users, this is no problem because downloads of Web pages, graphics, and files are the major use of Internet connections. Maximum downstream speeds are up to 1.6Mbps, with up to 640Kbps upstream. Most vendors who offer ADSL provide varying levels of service at lower speeds and prices, as well. Voice calls are routed over the same wire using a small amount of bandwidth, making a single-line service that does voice and data possible. ADSL is more expensive to set up than some other forms of DSL because a splitter must be installed at the customer site, meaning that you must pay for a service call (also called a truck roll) as part of the initial setup charge.

- *CDSL (Consumer DSL).* A slower (1Mbps upstream) form of DSL that was developed by modem chipset maker Rockwell. It doesn't require a service call because no splitter is required at the customer site.
- *G.Lite (Universal DSL, and also called DSL Lite or Splitterless DSL).* Another version that splits the line at the telco end rather than at the consumer end. Downstream speeds range from 1.544Mbps to 6.0Mbps, and upstream speeds can be from 128Kbps to 384Kbps. This is becoming one of the most popular forms of DSL because it enables consumers to use self-install kits. Note that the DSL vendor might cap the service at rates lower than those listed earlier in the chapter; check with the vendor for details.
- *SDSL (Symmetrical DSL).* This type of DSL service provides the same speed for upstream as for downstream service. Generally, SDSL is offered to business rather than residential customers because it requires new cabling (rather than reusing existing phone lines). A long-term contract frequently is required.

Table 19.1 summarizes the various types of DSL.

Table 19.1 DSL Type Comparison

DSL Type	Description	Data Rate Downstream; Upstream	Distance Limit	Application
IDSL	ISDN Digital Subscriber Line	128Kbps	18,000 feet on 24-gauge wire	Similar to the ISDN BRI service but data only (no voice on the same line)
CDSL	Consumer DSL from Rockwell	1Mbps downstream; less upstream	18,000 feet on 24-gauge wire	Splitterless home and small business service; similar to DSL Lite
DSL Lite (same as G.Lite)	Splitterless DSL without the truck roll	From 1.544 Mbps to 6Mbps downstream,depending on the subscribed service	18,000 feet on 24-gauge wire	The standard ADSL; sacrifices speed for not having to install a splitter at the user's home or business
HDSL	High bit-rate Digital Subscriber Line	1.544Mbps duplex on two twisted-pair lines; 2.048Mbps duplex on three twisted-pair lines	12,000 feet on 24-gauge wire	T-1/E1 service between server and phone company or within a company; WAN, LAN, server access
SDSL	Symmetric DSL	1.544Mbps duplex (U.S. and Canada); 2.048Mbps (Europe) on a single-duplex line downstream and upstream	12,000 feet on 24-gauge wire	Same as for HDSL but requiring only one line of twisted pair

Table 19.1 Continued

DSL Type	Description	Data Rate Downstream; Upstream	Distance Limit	Application
ADSL	Asymmetric Digital Subscriber Line	1.544Mbps to 6.1Mbps downstream; 16Kbps to 640Kbps upstream	1.544Mbps at 18,000 feet; 2.048Mbps at 16,000 feet; 6.312Mpbs at 12,000 feet; 8.448Mbps at 9,000 feet	Used for Internet and Web access, motion video, video on demand, and remote LAN access
RADSL	Rate-Adaptive DSL from Westell	Adapted to the line, 640Kbps to 2.2Mbps downstream; 272Kbps to 1.088Mbps upstream	Not provided	Similar to ADSL
UDSL	Unidirectional DSL proposed by a company in Europe	Not known	Not known	Similar to HDSL
VDSL	Very High Digital Subscriber Line	12.9Mbps 52.8Mbps downstream; 1.5Mbps to 2.3Mbps upstream; 1.6Mbps to 2.3Mbps downstream	4,500 feet at 12.96Mbps; 3,000 feet at 25.82Mbps; 1,000 feet at 51.84Mbps	ATM networks; Fiber to the Neighborhood

Table copyrighted by and used with permission of whatis.com, Inc.

With any type of DSL, an external device called a DSL *modem* is attached to the computer through either

- A crossover cable running to a 10BASE-T or 10/100 Ethernet card or port in the computer
- A USB cable running to a USB port in the computer

An RJ-11 (standard telephone) cable is attached between the DSL modem and the RJ-11 port that has been set up for DSL service.

To prevent telephone signals from interfering with DSL frequencies, splitters or microfilters must be installed on a DSL line. If you choose a technician-installed form of DSL, a device called a *splitter* is used at your location to prevent interference. Splitter-based DSL allows faster speeds than splitterless DSL installations, but the wait for a technician to show up and add the splitter can add days or weeks to your installation process.

If you self-install DSL, you will install small devices called *microfilters* to block interference from telephones, answering machines, and similar devices. These devices might fit behind the faceplate of the wall outlet used for DSL service or inline between the phone, answering machine, or fax machine and the wall outlet (see Figure 19.2).

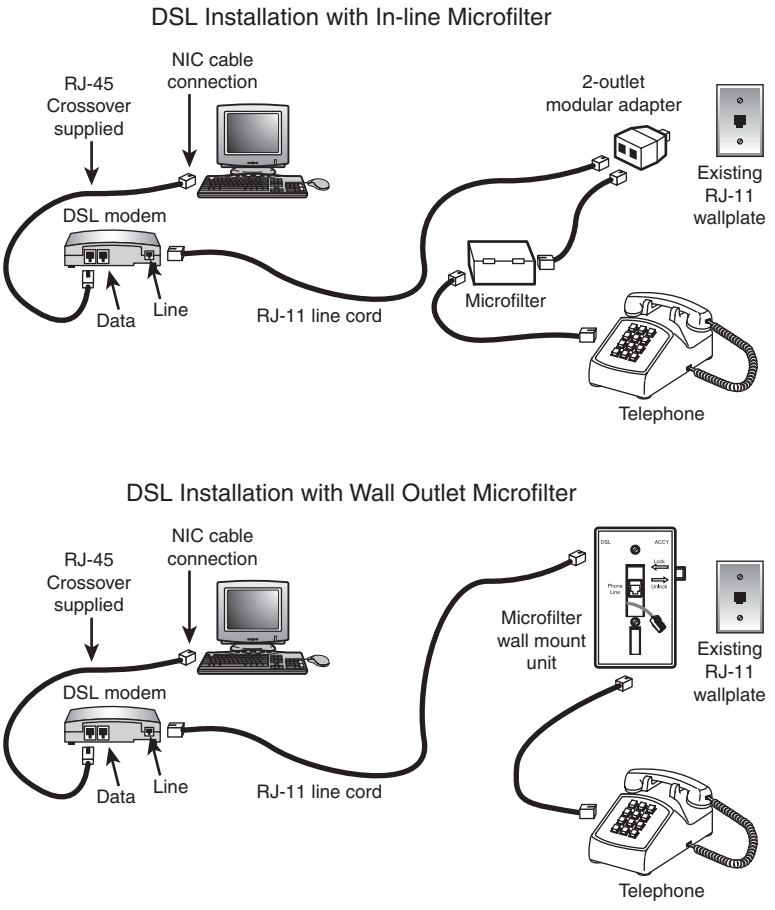

Figure 19.2 Two types of DSL self-installations; if a splitter is used to set up a separate DSL line, the microfilters shown here are not necessary.

Tip

If you have a security system attached to your telephone line, watch out for problems if you select DSL as your preferred broadband access method. Security systems are often designed to seize the line, interrupting a phone call in progress to send an alarm to the security company. This feature won't work with normal microfilters, so you should purchase a special DSL Alarm filter to allow your alarm system to coexist with your DSL installation. Get more information about the alarm microfilter and alternative DSL installation options from `www.hometech.com/learn/dsl.html`.

DSL Pricing

DSL pricing varies widely, with different telephone companies offering different speeds of DSL and different rates. One thing that's true about the most commonly used flavors of DSL is that they are usually an asymmetrical service—with download speeds faster than upload speeds. ADSL installations can typically be run over existing copper wires, whereas SDSL installations usually require that new high-quality copper wires be installed between the CO and the subscriber's location.

For unlimited use, typical residential DSL pricing ranges anywhere from $50 to $80 a month depending on the download speed, which ranges from 256Kbps to 1.5Mbps. Business DSL pricing ranges from $50 to as high as $500 per month.

The wide variance is partly due to the upload speeds permitted. The lower-cost plans typically use a lower upload speed (some variation on ADSL or G.Lite); in contrast, the more expensive plans often use SDSL. Check carefully with your vendor because your traditional telephone company might not be the only DSL game in town. Some major cities might have as many as half a dozen vendors selling various flavors of DSL.

Time Versus Access

Some so-called *Personal DSL* plans give you an interesting puzzle: time online versus data transfers.

Before the advent of unlimited Internet access, the time you spent online and the speed of your modem were the two variables used to calculate the cost per hour of services such as the original CompuServe. I remember looking for files on CIS at 2,400bps because surfing the site was cheaper that way, noting the files needed, and then hanging up and downloading them at the "blazing" speed of 9,600bps (a speed that cost you extra to use some years ago).

Some Personal DSL plans have gone back to a consumption-based pricing scheme. But with consumption-based Personal DSL plans, the speed of your connection and the time you spend are unimportant—it's the amount of data transfer you perform.

For many people, this isn't a major issue. For example, with US Family.net's Personal DSL - External IP plan (which provides a fixed IP address ideal for online gaming), 2,000MB (2GB) per month of data transfer is included at no extra charge and users pay just $2/month for each 100MB of additional data transfer.

Unless you're routinely downloading massive software service packs; hosting a game, Web, or NetMeeting server; or working beyond the fringes of legality by downloading entire CDs, this limitation is more apparent than real. Even though every Web page and graphic you view on the Web counts as a file transfer, the sizes of GIF, JPG, and HTML pages are usually miniscule. Still, find out what the file-transfer limitations are before you sign up for any type of metered DSL.

DSL Security Issues

Unlike other types of broadband access, DSL is a direct one-to-one connection that isn't shared; you have no digital "neighbors" who could casually snoop on your activities. However, as with any broadband "always-on" connection, intrusion from the Internet to your computer is a very real possibility.

▶▶ For more information on securing any type of Internet access, see "Securing Your Internet Connection," p. 1071.

Technical Problems with DSL

Telecommunications has always had its share of difficulties, starting with the incredibly slow and trouble-plagued 300bps modems used on early PCs, but as speed increases, so do problems. DSL connections are often very difficult to get working correctly because DSL, as you've seen, combines the problems of adding high-speed data access to the telephone line with network configuration using TCP/IP (the most powerful and most complex network protocol in widespread use; see Chapter 20, "Local Area Networking," for details).

A review of comments from DSL users in various forums, such as DSLReports.com and others, shows that the most common problems include the following:

- *Poor coordination between the DSL sales department of the telco or third-party provider and the installers.* This can lead to broken or very late appointments for installation; if possible, contact the installer company to verify the appointment. If possible, opt for a self-install version of DSL to avoid problems with late or missing appointments.
- *Installers who install the hardware and software and then leave without verifying it works properly.* Ask whether the installer carries a notebook computer that can test the line; don't let the installer leave until the line is working.
- *Poor technical support before and after installation.* Record the IP address and other information used during the installation; read reviews and tips from sources listed earlier in the chapter to help you find better DSL providers and solutions you can apply yourself or ask your telco or provider to perform.
- *Lower speeds than anticipated.* This can be due to a poor-quality connection to the telco from your home or business or problems at the central switch; ask the installer to test the line for you during initial installation and tell you the top DSL speed the line can reach. On a healthy line, the problem is often traceable to a very low value for the Windows Registry key called `RWIN` (receive window), which should be adjusted from its default of 8192 (8KB) to a value as high as 32768 (32KB) or even 65535 (64KB). If your system previously was used with a dial-up modem, the value for `RWIN` can be as low as 2144; low values force your DSL connection to receive data at rates hardly faster than those for a dial-up analog modem connection. For interactive tests that will help you find the best value to use for `RWIN` or other Registry options, find line problems, and adjust your configuration, go to `http://www.dslreports.com` and follow the DSLR Tools link from the home page.

Because of the problems with trying to retrofit an aging voice-oriented telephone network with high-speed Internet service, many pure DSL companies are having financial problems. Some once-prominent DSL ISPs went out of business in 2000–2001, leading to service cancellations in some cases. Before you sign a long-term contract for DSL service, you should determine what your options are if your telco, DSL line provider, or ISP drops DSL service.

Fixed-Base Wireless Broadband

If you're beyond the reach of CATV-based Internet or DSL and aren't interested in trying to install a satellite dish, you still might be able to get broadband Internet service through a fixed wireless broadband Internet provider.

Fixed wireless broadband should not be confused with text-only or limited-graphics wireless Internet services aimed at handheld mobile phones and PDAs. After a fixed-base wireless broadband signal reaches your computer, your Internet experience is just as rich in content and about as speedy as wired services such as cable modem and DSL. Essentially, fixed wireless broadband Internet access is a

form of cable modem service that substitutes microwave receivers or transceivers for the HFC cabling of the cable modem network. Similar to cable modems, fixed wireless broadband is an always-on service.

How Fixed-Base Wireless Broadband Works

Fixed-base wireless broadband is an offshoot of wireless CATV broadcasting; both use microwave towers to broadcast encrypted signals to receivers within a specified radius (35 miles or less) of the transmitter. Wireless CATV delivers the same cable TV content that conventional CATV operators provide for rural users and others who aren't served by conventional CATV services.

Similarly, fixed-base wireless broadband delivers encrypted Internet content to customers within the radius of the transmitter. If only a single transmitter/receiver site is used, the distance for two-way service can be significantly less than that available for wireless CATV users—as little as 15–20 miles. Because of the directional nature of the receiving antennas used for fixed-base wireless broadband, only some of the users in that radius might qualify for two-way service. Users who live within the radius served by the transmitter but don't qualify for two-way service might be eligible for one-way (also called telco return) service, which uses wireless signals for downloading only and an analog modem for uploading. Some fixed wireless broadband services offered in larger cities might use multiple transmitters, enabling all users to enjoy two-way service. Wireless signals are similar in their bandwidth use and modulation to CATV cable modem signals; in fact, some wireless broadband routers (which serve the same function as cable modems but are used for wireless networking) can also be used in CATV cable modem service.

Figure 19.3 compares the two forms of fixed-base wireless broadband Internet service.

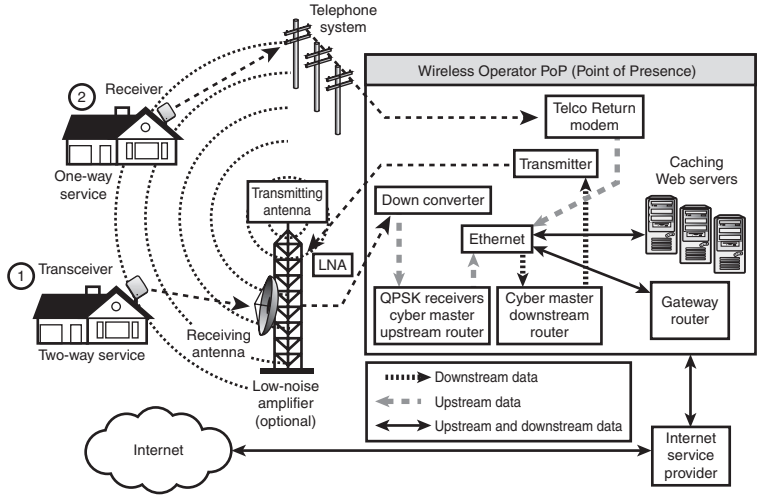

Figure 19.3 A two-way fixed-base wireless broadband service (1) uses wireless signals for both downloaded and uploaded data, whereas a one-way service (2) uses an analog modem and the telephone network for uploaded data and wireless signals for downloaded data only.

Several frequencies are used for fixed wireless broadband Internet, but the two most commonly used service types are

- *MMDS.* The most common form of fixed wireless broadband Internet has a range of up to 35 miles. It's used by Hybrid Networks, Spike Broadband Systems, and Vyyo. It uses the 2.5GHz–2.7GHz and 3.4GHz–3.7GHz frequencies. MMDS uses the same modulation techniques (QPSK and QAM) used by cable modems.
- *LDMS Lite.* Has a range of 3–5 miles and is used by Vyyo. It uses the 10MHz–43MHz frequencies and the QPSK and QAM modulation techniques.

Fixed wireless broadband can also use UHF and unlicensed frequencies.

Major fixed wireless broadband equipment and services vendors include

- Hybrid Networks (`www.hybrid.com`)
- Spike Broadband Systems (`www.integritybroadband.com`)
- Vyyo (`www.vyyo.com`)

Even though these companies have installed a number of service sites around the U.S., fixed wireless broadband is more popular outside the U.S., partly because of a lack of wired telephone or cable TV infrastructure (and thus a lack of competition from broadband Internet services based on those technologies).

The Wireless Broadband Router and Other Equipment

The connection between the wireless broadband service and your computer is provided by a wireless broadband router (also referred to as a WBR or wireless cable modem). A WBR resembles an external cable modem, but most models also include either an RS-232 connection to an external analog phone modem or an integrated analog modem, enabling the same WBR to be used in either two-way or one-way (telco return) service, as shown in Figure 19.4.

The WBR is connected via the same type of coaxial cable used by CATV cable modems to various types of receivers (for one-way service) or transceivers (for two-way service) that are mounted on the roof or on a tower. The placement of the transceiver or receiver is critical, especially in systems that use only one transmitter/receiver location. A site survey performed by the provider usually is required to verify that the service is available and to select a location for the transceiver/receiver's antenna.

If a direct line of sight back to the transmission/receiving tower can't be established, two-way service is not possible. However, one-way service might be available if the signal can be reflected off a nearby tower or building. Devices referred to as *benders* can be mounted on nearby structures to permit receiving of the signal from the wireless broadband provider, but benders can't be used to return data from the customer back to the provider's receiver.

Fixed Wireless Service Pricing and Availability

Generally, fixed wireless broadband Internet service is provided by companies that also provide wireless CATV. Service pricing and speeds tend to fall between typical cable modem and DSL offerings in many markets. Depending on the provider, you might be able to choose from several speeds (a provider in southern Indiana, for example, offers 128Kbps, 512Kbps, and 1.5Kbps rates) or a single speed of 512Kbps or faster.

Unlike cable modem service, though, users of fixed wireless broadband services might have to buy—and not have the option of leasing—their equipment. Because several companies provide fixed wireless receivers, transmitters, and WBR hardware and because no single standard exists (as does with

DSL or cable modems), there's no retail market for WBR devices. And, because different locations require different tower and antenna installations, your up-front cost is higher than with most other broadband service types, including even ISDN.

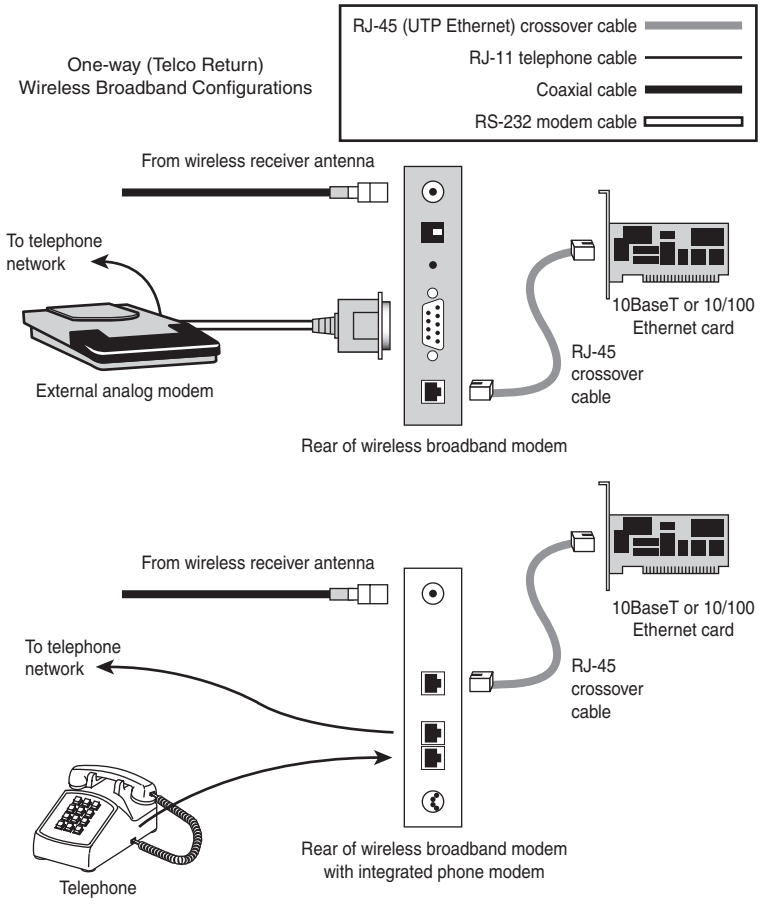

Figure 19.4 A typical wireless broadband router connects to coaxial cable coming from the receiver/transceiver. If the unit is used in one-way service, it can be attached to an external analog modem (top) or include an analog modem (bottom).

To get the best deals, compare the cost of month-to-month service with a longer contract. Some vendors charge for installation, whereas others might waive it at certain times or if you sign a long-term contract.

To find a fixed wireless provider in your area, you can

- Contact your wireless cable TV provider.
- Check the Cable Datacom News' list of wireless broadband trials and deployments at `www.cabledatacomnews.com/wireless/cmic12.html`.

- Check the fixed broadband wireless vendor Web sites listed earlier in this chapter; their news pages provide the latest locations where they have installed service.

Note

Because of the line-of-sight issues present with current generations of fixed wireless broadband equipment, one major nationwide supplier—Sprint Broadband Direct—stopped expanding its service areas and subscriber list in late 2001.

Fixed Wireless Security Issues

All fixed wireless broadband services are encrypted—even the one-way offerings—so casual snooping by others receiving the signal is impossible. However, you should guard against other types of Internet intrusion common to all forms of Internet access.

▶▶ For more information on securing any type of Internet access, see "Securing Your Internet Connection," p. 1071.

Internet Connectivity via Satellite with DirecWAY or StarBand

If you're in an area where cable TV doesn't exist, or you already have a DirecTV or Dish Network satellite dish, take a look at the southern sky from your home, condo, or apartment building. If you have a good, clear 45° window view to the sky toward the equator and you want fast downloads of big files, a satellite-based service such as DirecWAY (formerly DirecPC) or StarBand might be the high-speed choice for you.

Note

Geosynchronous satellites used for satellite Internet/TV service are visible in the southern sky for users in the Northern Hemisphere (North America, Europe, and Asia); if you're in the Southern Hemisphere (South America, Australia, Africa), these satellites are located in the northern sky.

Depending on the product you choose for satellite Internet, you might be able to use a single dish for both satellite Internet and satellite TV.

Tip

If you want both high-speed Internet access and satellite TV with a single dish, you can add DirecTV to the DirecWAY dish at any time. The StarBand dish works with both Dish Network (TV) and StarBand (Internet) services. However, if you decide to add DirecWAY to an existing DirecTV setup, you will need to replace your existing DirecTV dish unless you installed the larger DirecDUO dish (which works with DirecTV and DirecPC or DirecWAY).

DirecWAY (formerly DirecPC)

In mid-2001, Hughes Network Systems renamed its DirecPC satellite Internet service DirecWAY. Despite the name change, DirecWAY can still be confusing for some customers because it is available in two different forms, just as it was when it was called DirecPC. The original version of DirecPC/DirecWAY, and the only version available until early 2001, is strictly a hybrid system, meaning that incoming and outgoing data streams and other operations are actually routed two different ways:

- Downloading uses the 400Kbps (peak speed) satellite connection. At top speed, a DirecWAY customer can receive data at speeds about seven times faster than with a 56Kbps modem. Peak traffic loads can slow the satellite-based service download speed.
- Uploads and Web page requests require the use of a conventional analog modem.

One-way DirecWAY works as shown in Figure 19.5.

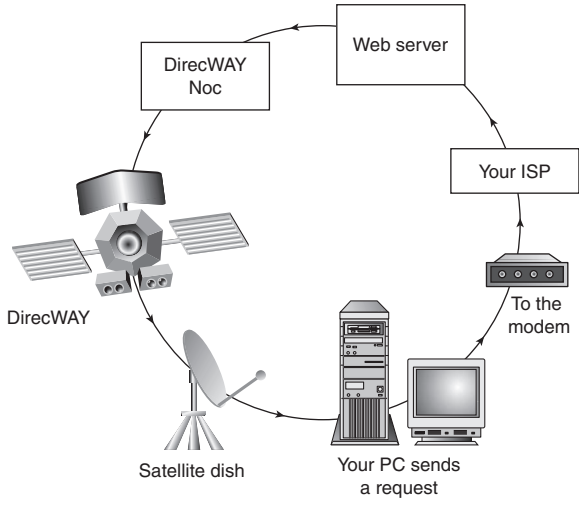

Figure 19.5 One-Way DirecWAY routes your request for Web pages, graphics, and files using a modem. The speed advantage comes when you receive your data, with a download speed of 400Kbps, thanks to a satellite link.

One-way service remains a part of the renamed DirecWAY family, but it's not the best choice for users who want to do more Web surfing than downloading and want to keep their telephone line freed up. If you need fast speed plus no interference with your telephone line from a DirecWAY satellite Internet system, you should consider the newer member of the DirecWAY family: two-way DirecWAY service.

DirecWAY Requirements

Both types of DirecWAY service require you to purchase and install a small satellite dish, similar but not compatible to those used for DirecTV and USSB satellite services. You can add DirecTV to DirecWAY service at any time because the DirecWAY satellite dish is also compatible with DirecTV signals. The dish is connected to what's called a satellite modem, a USB device used to receive data.

One-way DirecWAY service uses an analog modem (33.6Kbps or faster) for sending out page requests or uploading data. Although all services beyond 33.6Kbps are asymmetrical (faster for downloading than uploading) except ISDN, the only other fast-download Internet service with a similarly poky speed for uploads is the 56Kbps V.90 modem and its proprietary predecessors (x2 and K56flex).

Two-way DirecWAY service uses the 35" wide DirecWAY satellite dish to send and receive data.

Both forms of DirecWAY work with Windows 98SE, Windows 2000, Windows Me, and Windows XP on systems with a 333MHz AMD K6 or Intel Pentium II-class processor or faster. Windows 98SE and

Windows Me systems need at least 64MB of RAM, whereas Windows 2000 and Windows XP systems need at least 128MB of RAM. The software installs from a CD-ROM drive. Regardless of the service type you select, you will need an analog modem. Your analog modem is used only for initial account setup (a process called *commissioning* by DirecWAY) with a two-way system, but it's used for all outgoing traffic with a one-way DirecWAY system.

Purchasing DirecWAY Service

One-way DirecWAY is technologically the same as DirecPC 4.0, but its market has changed. Throughout most of DirecPC's life, it was sold under the Hughes Network Systems brand name of DirecPC. Now, as DirecWAY, the one-way service can be purchased under either the DirecWAY or AOL High-Speed Satellite brand name. Note that AOL High-Speed Satellite service (previously called AOL Plus Powered by DirecPC) is more costly than plain DirecWAY service because it includes all the AOL features as well as Internet access. Both forms of one-way DirecWAY service include unlimited hours; the previous 25-hours-per-month DirecPC service plans are no longer available. Equipment (dish, satellite modem, and mounting hardware) costs around $150, and some vendors include professional installation in the selling price.

Two-way DirecWAY service is available from several partners in the U.S., including these:s

- *Earthlink*. Earthlink Satellite Powered by DirecWAY; `www.earthlink.com`
- *Pegasus*. Pegasus Express; `www.pgtv.com`
- *National Rural Telecommunications Cooperative (NRTC)*. `www.nrtc.org`; call your rural electric/telephone cooperative or independent telephone company for details

Unlike DSL and cable broadband services, which often bundle the cost of the broadband modem with the monthly service charge over the life of your contract, DirecWAY requires you to buy the satellite dish and satellite modem up front for several hundred dollars. You also must have the system professionally installed at additional cost, although some vendors provide price breaks on equipment or installation. Monthly service charges are around $70/month.

Check the Get DirecWAY Service link at the DirecWAY Web site (`www.direcway.com`) for the latest vendor and pricing information.

One-way DirecWAY service can be installed by a professional installer or by the user. Installing one-way DirecWAY service combines the dangers of satellite-TV installation with the usual issues involved in connecting a network-style device to your computer. You'll need an unobstructed 45° clear line of sight toward the satellites and room for the 21" satellite dish.

Installation instructions supplied with one-way DirecWAY equipment strongly suggest that one-way DirecWAY installers have experience with typical satellite dishes or TV antennas because issues such as running coaxial cable, proper electrical grounding to code, and other challenges await. Detailed installation instructions for the antenna and other DirecWAY components are found on the CD-ROM that comes with the self-installation kit. Consider professional installation for a carefree, reliable, and safe setup of your one-way DirecWAY system at a reasonable price if you're not familiar with working with satellite dish or cable TV hookups.

DirecWAY's FAP—Brakes on High-Speed Downloading?

A big concern for those wanting to exploit the high-speed download feature continues to be DirecWAY's Fair Access Policy (FAP), which was introduced long after the original DirecPC service was started. FAP uses unpublished algorithms to determine who is "abusing" the service with large downloads. Abusers have their download bandwidths reduced by about 50% or more until their behavior changes. A class-action lawsuit was filed in July 1998 by DirecPC users who objected to this policy.

Users said that Hughes Network Systems, Inc., the developer of DirecPC, was simultaneously selling the system on the basis of very fast download times and then punishing those who wanted to use it in the way DirecPC had sold it to the public.

As a result of the class-action lawsuit, DirecWAY partners' Web sites, such as `www.pgtv.net/FAP.html`, now offer usage guidelines that are supposed to help you avoid being "FAPped." However, many DirecPC and DirecWAY users whose comments are available on the `alt.satellite.direcpc` newsgroup (also available via the `groups.google.com` Web site) complain that the guidelines are misleading. For example, the current guidelines state that if you download more than 169MB during the period from 5 a.m. to 2 a.m. the following morning (21 hours), you will exceed the maximum usage threshold for FAP, and your download speed will be severely slowed down.

DirecWAY recommends that to avoid being FAPped, users should take advantage of the Turbo Newsgroups and Turbo Webcasts features available with various DirecWAY service plans. These "push" newsgroup and selected Web site content to subscribers' systems without the traffic being counted for FAP calculation purposes.

Note

I'm concerned about FAP limitations when it's time to download the increasingly bulky service packs for operating systems, Web browsers, and office suites. Some users have reported their service speeds dropping by 50% or more after downloading just 40MB of files. At a time when a single service pack can be about 40MB by itself, this isn't good news. Because DirecWAY refuses to release details of its FAP-calculating algorithm and its public guidelines seem misleading, you should probably avoid downloading a lot of large files in sequence if you want to avoid being FAPped.

Because different satellites are used by the different DirecWAY partners, it pays to research which DirecWAY versions perform best. In addition to the DirecPC/DirecWAY newsgroup, check out the DirecPC Uncensored! Web site at `www.copperhead.cc` for speed tests and tweaks you can make to your system.

DirecWAY's Real-World Performance

Benchmark addicts will find that both forms of DirecWAY perform poorly on ping tests because the complex pathway your data must travel (ground to space and back again) results in pings taking at least 400ms–600ms. Interactive benchmarks are also disappointing. The hybrid (telco out, satellite in) design of one-way DirecWAY is an obvious reason that this form of DirecWAY software is a very poor choice for Internet gaming, teleconferencing, and Internet telephony. However, the delays caused by communicating with a geosynchronous satellite over 22,500 miles in space make two-way DirecWAY little better for these applications. Speeds vary widely, but according to DirecPC Uncensored!, one-way DirecWAY is capable of downloads over 900Kbps at times, and two-way DirecWAY can reach download speeds over 2,000Kbps. To achieve results like this, use the tips available on the DirecPC Uncensored! Web site to adjust your system's configuration.

StarBand

In April 2000, StarBand—the first consumer-oriented two-way satellite network—was introduced after being tested as Gilat-At-Home. StarBand's partners include Gilat Satellite Networks, Microsoft Corporation, and EchoStar Communications (the marketer of Dish Network satellite TV service).

StarBand uses an external USB modem and a satellite dish that supports both StarBand Internet and Dish Network satellite TV. In fact, the feature set of two-way DirecWAY is almost identical to StarBand.

StarBand and two-way DirecWAY service work as shown in Figure 19.6.

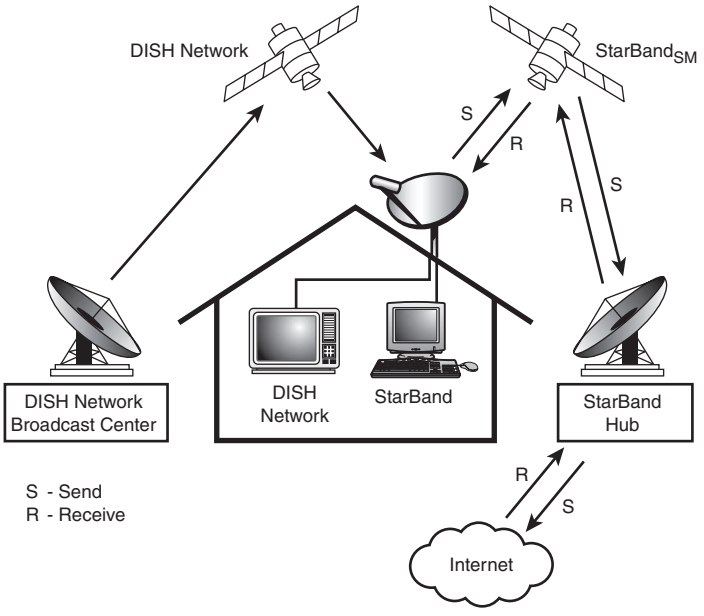

Figure 19.6 The StarBand service can receive both Dish Network TV programs (left) and StarBand Internet traffic (right) with its single 24"×36" satellite dish. Two-way DirecWAY service also supports both TV and Internet on its single dish and works in a similar fashion.

StarBand provides download speeds ranging from 150Kbps to 500Kbps and upload speeds ranging from 50Kbps to 150Kbps. The current version of StarBand uses the StarBand Model 360 satellite modem, a smaller, faster model than the original Model 180. Model 360 can be interfaced through either USB or Ethernet ports. If your StarBand unit was shipped with the Model 180 satellite modem, contact StarBand for upgrade details. StarBand supports Windows 98/98SE, Windows Me, Windows 2000, and Windows XP.

StarBand has partnered with several other companies, including Dish Network (`www.dishnetwork.com`), NRTC (`www.nrtc.org`), and US Online (`www.usonline.com`). StarBand equipment pricing and monthly service fees are generally similar to DirecWAY two-way's price structure, although some vendors might offer special promotional packages and bundles.

Tip

You can find excellent tips, tricks, utility software, and user-provided help at the StarBand Users Web site: `www.starbandusers.com`.

Integrated Services Digital Network

The connection speed of analog modems is limited by Shannon's Law (see the section "56Kbps Modems," later in this chapter). To surpass the speed limitations of analog modems, you need to use digital signals. Integrated Services Digital Network (ISDN) was the first step in the move to digital telecommunications. With ISDN, you can connect to the Internet at speeds of up to 128Kbps. Because ISDN was developed by the telephone companies, you can purchase a variety of service plans.

Depending on the ISDN service you choose, you can use it strictly for Internet service or use it to service multiple telephony applications such as voice, fax, and teleconferencing.

Depending on where you live, you might find that ISDN service is available for Internet uses, or your local telco might offer faster DSL service as an alternative. Because ISDN was not originally designed for Internet use, its speed is much lower than other broadband options. Also, ISDN costs about twice what a typical ADSL or cable modem connection costs per month.

ISDN doesn't require as high a line quality as DSL, so it can be offered in areas where DSL can't work without a major upgrade of the telephone system.

How Standard ISDN Works

Because ISDN carries three channels, it allows integrated services that can include combinations such as voice+data, data+data, voice+fax, fax+data, and so on (see Figure 19.7).

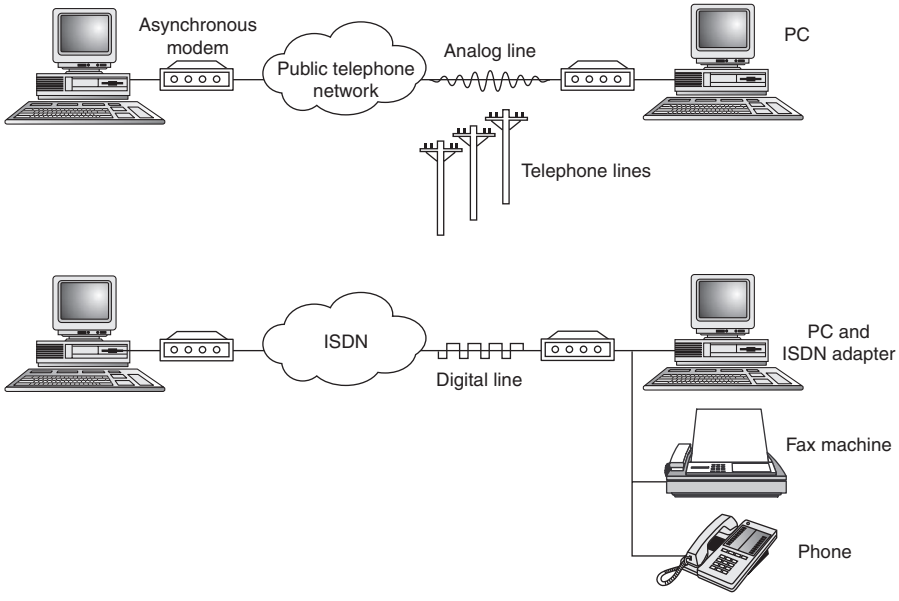

Figure 19.7 An analog modem connection (top) connects only your PC to the Internet or other online services, whereas ISDN (bottom) can connect your computer, fax, and many other devices via a single ISDN terminal adapter.

On a standard ISDN connection, bandwidth is divided into bearer channels (B channels) that run at 64Kbps and a delta channel (D channel) that runs at either 16Kbps or 64Kbps, depending on the type of service. The B channels carry voice transmissions or user data, and the D channel carries control traffic. In other words, you talk, surf, or fax through the B-channel lines.

Two types of ISDN service exist: basic rate interface (BRI) and primary rate interface (PRI). The BRI service is intended for private and home users and consists of two B channels and one 16Kbps D channel, for a total of 144Kbps. The typical BRI service enables you to use one B channel to talk at 64Kbps and one B channel to run your computer for Web surfing at 64Kbps. Hang up the phone, and both B channels become available. If your ISDN service is configured appropriately, your Web browsing becomes supercharged because you're now running at 128Kbps.

The PRI service is oriented more toward business use, such as for PBX connections to the telephone company's central office. In North America and Japan, the PRI service consists of 23 B channels and 1 64Kbps D channel for a total of 1,536Kbps, running over a standard T-1 interface. In Europe, the PRI service is 30 B channels and 1 64Kbps D channel, totaling 1,984Kbps, which corresponds to the E1 telecommunications standard. For businesses that require more bandwidth than one PRI connection provides, 1 D channel can be used to support multiple PRI channels using non-facility associated signaling (NFAS).

The BRI limit of two B channels might seem limiting to anyone other than a small office or home office user, but this is misleading. The BRI line can actually accommodate up to eight ISDN devices, each with a unique ISDN number. The D channel provides call routing and "on-hold" services, also called *multiple call signaling*, allowing all the devices to share the two B channels.

Note

When speaking of ISDN connections, 1 kilobyte equals 1,000 bytes, not 1,024 bytes as in standard computer applications.

As you saw earlier, this is also true of speed calculations for modems. Calculations that use 1,000 as a base are often referred to as *decimal* kilobytes, whereas the ones based on 1,024 are now called *kibibytes* or *binary* kilobytes.

If you need a more powerful, more flexible (and more expensive) version of ISDN, use the PRI version along with a switching device, such as a PBX or server. Although PRI allows only one device per B channel, it can dynamically allocate unused channels to support high-bandwidth uses, such as videoconferencing, when a switching device is in use along with PRI.

Acquiring ISDN Service

To have an ISDN connection installed, you must be within 18,000 wire feet (about 3.4 miles or 5.5km) of the CO (telco central office or central switch) for the BRI service; *wire feet* refers to the distance traveled by the telephone wires serving your location, not straight-line distance. For greater distances, expensive repeater devices are needed, and some telephone companies might not offer the service at all.

Prices for ISDN service vary widely depending on your location. In the United States, the initial installation fee can range from $35 to $150, depending on whether you are converting an existing line or installing a new one. The monthly charges typically range from $30 to $50, and sometimes you must pay a connect-time charge as well, ranging from 1 to 6 cents per minute or more, depending on the state. Keep in mind that you also must purchase an ISDN terminal adapter for your PC and possibly other hardware as well, and these charges are only for the telephone company's ISDN service. In addition, you must pay your ISP for access to the Internet at ISDN speeds. Typically, when all charges are included, you can pay up to $100 or more per month for ISDN service in a residential setting, and more for a small business connection. Residential plans are often dial-up, requiring you to make a connection to the ISP's server every time you want to go online, whereas business plans are usually always-on, with immediate connection.

Note

Although ISDN Internet access provided by your local telephone company usually has a single price for the ISDN line and ISDN Internet access, most third-party ISDN ISPs provide pricing for only Internet access. These costs might appear to be much less expensive at startup and per month than what the telco's ISDN package costs, but this is misleading because the telco's charges for ISDN service aren't included. Add up the costs from both the ISP and the telephone company for a true picture of third-party ISDN Internet service pricing.

Because ISDN pricing plans offer many options depending on the channels you want and how you want to use them, be sure you carefully plan how you want to use ISDN. Check the telco's Web site for pricing and package information to get a jump on the decision-making process. Although ISDN is unique among broadband Internet services for its capability to handle both voice and data traffic, its relatively high cost and low speed make it a poor choice for most small-office and home-office users.

ISDN Hardware

To connect a PC to an ISDN connection, you must have a hardware component called a *terminal adapter (TA)*. The terminal adapter takes the form of an expansion board or an external device connected to a serial port, much like a modem. In fact, terminal adapters often are mistakenly referred to as ISDN modems. Actually, they are not modems at all because they do not perform analog/digital conversions.

Because an ISDN connection originally was designed to service telephony devices, most ISDN terminal adapters have connections for telephones, fax machines, and similar devices, as well as for your computer. Some terminal adapters can also be used as routers to enable multiple PCs to be networked to the ISDN connection.

Caution

To achieve the best possible performance, you should either purchase an external ISDN terminal adapter that connects to your computer's USB port or use an internal version. A terminal adapter with compression enabled easily can exceed a serial port's capability to reliably send and receive data. Consider that even a moderate 2:1 compression ratio exceeds the maximum rated speed of 232Kbps, which most high-speed COM ports support. USB 1.1 ports, on the other hand, can handle signals up to 12Mbps, easily supporting even the fastest ISDN connection. USB 2.0 ports available on the latest computers support speeds up to 480Mbps.

Note

For more information about ISDN hardware and configuration, see *Upgrading and Repairing PCs, 11th Edition*, available in electronic form on the DVD-ROM packaged with this book.

Comparing High-Speed Internet Access

One way of making sense out of the confusing morass of plans available from cable modem, DSL, fixed wireless Internet, and satellite vendors is to calculate the average cost per Kbps of data downloaded ($/Kbps). You can calculate this figure yourself by dividing the service cost ($SC) per month by the rated or average speed of the service ($SPD):

$SC / $SPD = $/Kbps

For example, a typical cable modem service costs $50 per month, including cable modem lease, and has an average (not peak) speed of 500Kbps. Divide $50 by 500Kbps, and the cost per Kbps equals 10 cents.

Use this formula with any broadband or dial-up service to find the best values. Don't forget to calculate the cost of required equipment (as in the example). If you must pay for equipment or installation upfront—as you will need to do with satellite, fixed wireless, and ISDN Internet plans—divide the upfront cost by the number of months you plan to keep the service and add the result to the monthly service charge to get an accurate figure.

How does a typical 56Kbps modem compare, assuming 50Kbps download speeds? Using Juno Web ($14.95 per month) and assuming no charge for an analog modem, the cost per Kbps is 29.9 cents per Kbps—almost three times as much for service that is at least 10 times slower than a typical cable modem.

Generally, the services stack up as shown in Table 19.2, from slowest to fastest when download speeds are compared.

Table 19.2 Comparing Typical Speeds for Various Types of Internet Connections

Connection Type	Speed
V.34 annex analog modem	33.6Kbps
V.90/V.92 analog modem	53Kbps (due to FCC regulations; hardware capable of 56Kbps)
ISDN (1BRI)	64Kbps
ISDN (2BRI)	128Kbps
ADSL	384Kbps[1]
DirecWAY (one-way)	400Kbps
DirecWAY or StarBand (two-way)	500Kbps
Cable modem or fixed wireless	512Kbps[2]
ADSL	512Kbps[1]
ADSL	1GB[1]
Cable modem or fixed wireless	1.5Gbps[2]

The values in this table are estimated ratings from the vendor; substitute average actual values when available.

1. DSL bandwidth depends on the package you select; higher bandwidth packages carry higher monthly fees.

2. Cable modem/wireless bandwidth can depend on the package you select; higher bandwidth packages carry higher monthly fees. Also, speeds can vary with network traffic; ask vendor for details.

Another way to compare Internet connection types is by feature, as in Table 19.3.

Table 19.3 Comparing High-Speed Internet Access by Feature

Service	Always On?	Shared with Other Users?	Ties Up Phone Line?	Reliability Affected By?	Connect Type
Cable modem (two-way)	Yes	Yes	No	Cable outages	Ethernet or USB
Cable modem (one-way)	No	Yes	Yes	Cable outages; phone line outages	Ethernet or USB; might need external analog modem
Fixed wireless (two-way)	Yes	Yes	No	Transmitter outages	Ethernet
Fixed wireless (one-way)	No	Yes	Yes	Transmitter outages; phone line outages	Ethernet; might need external analog modem
DirecWAY (one-way)	No	No	Yes	Satellite outages; phone line outages	USB

Table 19.3 Continued

Service	Always On?	Shared with Other Users?	Ties Up Phone Line?	Reliability Affected By?	Connect Type
DirecWAY (two-way)	Yes	Yes	No	Satellite outages	USB
StarBand (two-way)	Yes	Yes	No	Satellite outages	USB
DSL	Yes	No	No	Phone line outages telco network changes	Ethernet or USB

Having a Backup Plan in Case of Service Interruptions

Because no high-speed connection is immune to service interruptions, you should consider having some type of backup plan in place in case of a significant service outage.

If your high-speed Internet access uses an ISP that can also accept 56Kbps connections, you might still be able to use your regular modem for emergencies. However, this might require an extra charge in some cases. You could also consider using a free trial subscription to an ISP that uses a conventional modem. If you temporarily switch to a different ISP—especially one that uses its own client, such as AOL—be sure to back up your current Internet configuration information before you install the client software. Your best bet is to use an Internet-only ISP whose dial-up connection can be configured manually with the Dial-Up Networking Connection Wizard. Then, you can construct a new connection without destroying your existing configuration.

If you don't want to spend $15–$25/month for backup service, or if you travel occasionally and want a low-cost way to work online when you're away from broadband, I recommend Slingshot prepaid Internet access (`www.slingshot.com`). Stores such as Staples, CompUSA, RadioShack, and others sell a Slingshot CD for $9.99. The CD contains the Slingshot setup software and up to 600 minutes of local access time or up to 200 minutes of toll-free access time. When you start the Slingshot service for the first time, Slingshot checks for local access numbers available in your area first; then, every time you connect, it offers the option to use a local number (for more time) or a toll-free number (when local numbers aren't available). You can buy additional minutes online or from the same outlets that sell the original CD. Slingshot, unlike some free Internet offers, can coexist with your broadband connection and the minutes don't expire.

A similar product designed for both U.S. and international travelers is the TeleAdaptUSA's MaGlobe Internet Access for the Traveler, which provides up to 30 hours of local access in the U.S., 5 hours of toll-free access in the U.S., or up to 6 hours of local access outside the U.S. MaGlobe is $30 and is compatible with Windows, Mac OS, and Palm computers, as well as with Internet-capable PDAs and cellular phones. Support for Pocket PCs is also planned.

Note

Each type of Internet connection uses a particular combination of TCP/IP settings. TCP/IP is the protocol (software rules) used by all computers on the Internet. TCP/IP is covered in Chapter 20, but for now keep in mind that different TCP/IP settings are required for modem access and access through a NIC or USB port device (cable modem, DSL, and DirecWAY or StarBand). Modems usually have an IP address provided dynamically by the ISP when the modem connects with the ISP. The other types of Internet access devices might have static IP addresses that don't change or have dynamically assigned IP addresses. IP addresses are just one of the network settings that, if changed, prevent you from connecting to the Internet.

Leased Lines

For users with high bandwidth requirements (and deep pockets), dedicated leased lines provide digital service between two locations at speeds that can far exceed ISDN and are as fast or faster than DSL or cable modem. A *leased line* is a permanent 24-hour connection to a particular location that can be changed only by the telephone company. Businesses use leased lines to connect LANs in remote locations or to connect to the Internet through a service provider. Leased lines are available at various speeds, as described in the following sections.

T-1 and T-3 Connections

To connect networks in distant locations, networks that must support a large number of Internet users, or especially organizations that will be hosting their own Internet services, a T-1 connection might be a wise investment. A *T-1* is a digital connection running at about 1.5Mbps. This is more than 10 times faster than an ISDN link and is more than double the speed of most fast DSL connections. A T-1 can be split (or fractioned), depending on how it is to be used. It can be split into 24 individual 64Kbps lines or left as a single high-capacity pipeline. Some ISPs allow you to lease any portion of a T-1 connection that you want (in 64Kbps increments). Ameritech, for example, offers a flexible T-1 service it calls DS1; it's available at full bandwidth or in various fractional sizes. Figure 19.8 shows how a T-1 line is fractioned.

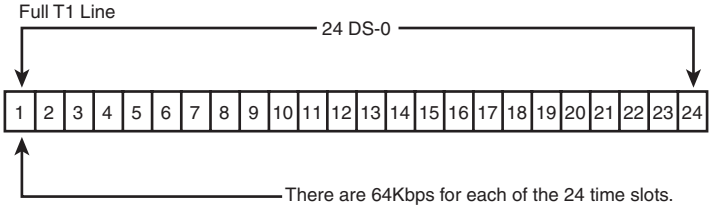

Figure 19.8 Full T-1 service uses all 24 lines (each one is 64Kbps) as a single pipeline; a fractional T-1 service of 256Kbps could use slots 1–4 only, for example.

An individual user of the Internet interacts with a T-1 line only indirectly. No matter how you're accessing the Internet (dial-up modem, ISDN, DSL, cable modem, DirecWAY, StarBand, or fixed-base wireless), your ISP typically will have a connection to one or more T-1 or T-3 lines, which connect to the backbone of the Internet. This connection to the backbone is sometimes referred to as a *point of presence (PoP)*. When you make your connection to the Internet, your ISP shares a small chunk of that T-1 pipe with you. Depending on how many other users are accessing the Internet at your ISP or elsewhere, you might experience very fast to slow throughput, even if your modem connection speed remains constant. It's a bit like splitting up a pizza into smaller and smaller slices to accommodate more people at a party: The more users of a high-speed connection, the slower each individual part of it will be. To keep user connections fast while growing, ISPs add full or fractional T-1 lines to their points of presence. Or, they might switch from a T-1 connection to the even faster T-3 if available.

Note

Equivalent in throughput to approximately 28 T-1 lines, a T-3 connection runs at 45Mbps and is suitable for use by very large networks and university campuses. Pricing information falls into the "if-you-have-to-ask-you-can't-afford-it" category.

If your Internet connection is on a corporate LAN or your office is located in a downtown building, your relationship to a T-1 line might be much closer. If your building or office is connected directly to a T-1, you're sharing the capacity of that line with just a relatively few other users rather than with the hundreds or thousands of dial-up users a normal ISP is hosting at one time. Full or fractional T-1 lines are being added to more and more apartments and office buildings in major cities to allow residents and workers faster Internet access. In these cases, a LAN connection to the T-1 is usually provided, so your Internet access device is a network card, rather than a modem or ISDN terminal adapter.

With the rise of the Internet and the demand for high-speed data access for networks, the price of T-1 links in the United States has fallen drastically since the late 1990s, although you will still pay in the hundreds of dollars for typical service offerings. T-1 service can be acquired from either your local telco or third-party firms. Fractional T-1 or burstable T-1 (which allows you to have differing levels of bandwidth up to the entire T1 1.5Mbps depending on demand) costs less than full T-1 service. For a large organization that requires a lot of bandwidth, the lower cost of T-1 services today make installing a higher-capacity service and growing into it—rather than constantly upgrading the link—more economical than ever. Although the speed of T-1 links resembles the maximum rates available with DSL or cable modem service, most types of T-1 service provide constant bandwidth (unlike cable modems) and bypass the potentially severe problems of trying to retrofit old phone lines with digital service (unlike DSL).

Comparing Conventional High-Speed Services

Some telcos who formerly posted pricing for ISDN, T-1, or other high-end telecommunications services now have a "call us" button on their Web sites because pricing is complicated by many factors, including

- Location (state and locality because telephone companies are regulated public utilities)
- Fixed and variable costs
- Usage
- Installation costs
- Your needs

Be sure to consider hardware and usage costs when you price services, and (for items such as ISDN terminal adapters and network cards) compare the official offerings with products available elsewhere. If you decide to provide some of the equipment yourself, find out whose responsibility repairs become. Some companies provide lower-cost "value" pricing for services in which you agree to configure the hardware yourself and maintain it. If you have knowledgeable staffers who can handle routers and other network configuration, you can save money every month, but if not, go with the full-service option.

Securing Your Internet Connection

Because any Internet connection must use TCP/IP, which uses built-in logical ports numbered 0–65,535 to service different types of activity, any user of the Internet can be vulnerable to various types of Internet attacks, even if precautions such as turning off drive and folder sharing have been followed. Such vulnerabilities increase drastically with always-on broadband services such as DSL and cable modems.

Steve Gibson of Gibson Research Corporation (makers of the classic SpinRite disk maintenance program) has established a free Web-based service called Shields Up that you should try with *any* Internet-connected PC to see how safe or vulnerable you are.

The Shields Up portion of the Gibson Research Corporation Web site (`http://www.grc.com`) probes your system's Internet connection security and Internet service ports.

After testing your system, Shields Up provides reviews and recommendations for proxy server and firewall software (such as ZoneAlarm, Norton Internet Security, and BlackICE Defender) that you can use to help secure your system.

With the increasing importance of the Internet and the multiple vulnerabilities we've seen since 2000 to Internet-borne viruses, Trojan horses, and denial-of-service attacks, Shields Up provides a valuable service for *any* Internet user.

Note

Proxy servers and firewalls are subjects that go far beyond the scope of this book. If you want to learn more, I suggest you pick up a copy of *Upgrading and Repairing Networks, Third Edition*, also published by Que.

Que's *Absolute Beginner's Guide to Personal Firewalls* by Jerry Lee Ford is another excellent resource for users who want to install a personal firewall, such as ZoneAlarm or BlackICE Defender, instead of a hardware firewall.

Asynchronous (Analog) Modems

If you want to connect to the Internet without spending a lot of money, an analog modem can serve as your on-ramp to the rest of the computing world. Modems are standard equipment with most recent systems and continue to be popular upgrades for systems that do not have access to broadband solutions, such as two-way cable modem or DSL lines. Even with some types of broadband access (such as One-way DirecWAY and one-way cable modem), modems are still needed to send page requests and email.

The word *modem* (from modulator/demodulator) basically describes a device that converts the digital data used by computers into analog signals suitable for transmission over a telephone line and converts the analog signals back to digital data at the destination. To distinguish modems that convert analog and digital signals from other types of access devices, modems are frequently referred to as *analog modems*; because you must dial a telephone number to reach a remote computer, they are also referred to as *dial-up modems*. The typical PC modem is an asynchronous device, meaning it transmits data in an intermittent stream of small packets. The receiving system takes the data in the packets and reassembles it into a form the computer can use.

Note

Because it has become such a familiar term, even to inexperienced computer users, the word *modem* is frequently used to describe devices that are, strictly speaking, not modems at all. For example, earlier in this chapter you read about broadband solutions such as ISDN, cable modems, DirecWAY, DSL, and StarBand. Although all these services use devices commonly called "modems" to connect your PC to fast online services, none of them converts digital information to analog signals. However, because these devices look similar to a standard modem and are used to connect PCs to the Internet or to other networks, they are called modems.

Asynchronous modems transmit each byte of data individually as a separate packet. One byte equals 8 bits, which, using the standard ASCII codes, is enough data to transmit a single alphanumeric character. For a modem to transmit asynchronously, it must identify the beginning and end of each byte to the receiving modem. It does this by adding a start bit before and after every byte of data, thus using 10 bits to transmit each byte (see Figure 19.9). For this reason, asynchronous communications

have sometimes been referred to as *start-stop* communications. This is in contrast to synchronous communications, in which a continuous stream of data is transmitted at a steady rate.

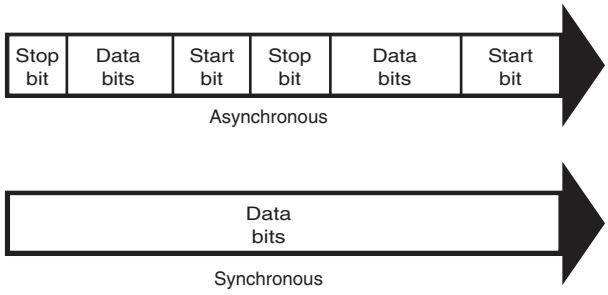

Figure 19.9 Asynchronous modems frame each byte of data with a start bit and a stop bit, whereas synchronous communications use an uninterrupted stream of data.

Synchronous modems generally are used in leased-line environments and in conjunction with multiplexers to communicate between terminals to Unix- or Linux-based servers and mainframe computers. Thus, this type of modem is outside the scope of this book.

Whenever modems are referred to in this book, I will be discussing the asynchronous, analog variety. (Synchronous modems are not found in typical computer stores and aren't included in normal computer configurations, so you might not ever see one unless you go into the data center of a corporation that uses them.)

Note

During high-speed modem communications, the start and stop bits are usually not transmitted over the telephone line. Instead, the modem's data compression algorithm eliminates them. However, these bits are part of the data packets generated by the communications software in the computer, and they exist until they reach the modem hardware. If both ends of an analog modem connection don't use the same value for start and stop bits, the connection transmits gibberish instead of usable data.

The use of a single start bit is required in all forms of asynchronous communication, but some protocols use more than one stop bit. To accommodate systems with different protocols, communications software products usually enable you to modify the format of the frame used to transmit each byte. The standard format used to describe an asynchronous communications format is parity/data bits/stop bits. Almost all asynchronous connections today are therefore abbreviated as N-8-1 (No parity/8 data bits/1 stop bit). The meanings for each of these parameters and their possible variations are as follows:

- *Parity.* Before error-correction protocols became standard modem features, a simple parity mechanism was used to provide basic error checking at the software level. Today, this is almost never used, and the value for this parameter is nearly always set to none. Other possible parity values you might see in a communications software package are odd, even, mark, and space.
- *Data Bits*. This parameter indicates how many bits are actually carried in the data portion of the packet (exclusive of the start and stop bits). PCs typically use 8 data bits, but some types of computers use a 7-bit byte, and others might call for other data lengths. Communications programs provide this option to prevent a system from confusing a stop bit with a data bit.

- *Stop Bits*. This parameter specifies how many stop bits are appended to each byte. PCs typically use 1 stop bit, but other types of protocols might call for the use of 1.5 or 2 stop bits.

In most situations, you will never have to modify these parameters manually, but the controls are almost always provided. In Windows 9x/Me/2000/XP, for example, if you open the Modems control panel and look at the Connection page of your modem's Properties dialog box, you will see Data Bits, Parity, and Stop Bits selectors.

Unless you use the Windows HyperTerminal program to establish a direct connection to another computer via phone lines, you might never need to modify these parameters. However, if you need to call a mainframe computer to perform terminal emulation for e-banking, checking a library's catalog, or working from home, you might need to adjust these parameters. (*Terminal emulation* means using software to make your PC keyboard and screen act like a terminal, such as a DEC VT-100 and so on.) Many mainframe computers use even parity and a 7-bit word length. If your PC is set incorrectly, you'll see garbage text on your monitor instead of the other system's login or welcome screen.

Modem Standards

For two modems to communicate, they must share the same *protocol*. A protocol is a specification that determines how two entities will communicate. Just as humans must share a common language and vocabulary to speak with each other, two computers or two modems must share a common protocol. In the case of modems, the protocol determines the nature of the analog signal the device creates from the computer's digital data.

Bell Labs (which set standards for early 300bps modems) and the CCITT are two of the bodies that have set standards for modem protocols. CCITT is an acronym for Comité Consultatif International Téléphonique et Télégraphique, a French term that translates into English as the Consultative Committee on International Telephone and Telegraph. The organization was renamed the International Telecommunication Union (ITU) in the early 1990s, but the protocols developed under the old name are often referred to as such. Newly developed protocols are called ITU-T standards, which refers to the Telecommunication Standardization Sector of the ITU. Most modems built in recent years conform to the standards developed by the CCITT/ITU.

The ITU, headquartered in Geneva, Switzerland, is an international body of technical experts responsible for developing data communications standards for the world. The group falls under the organizational umbrella of the United Nations, and its members include representatives from major modem manufacturers, common carriers (such as AT&T), and governmental bodies. The ITU establishes communications standards and protocols in many areas, so one modem often adheres to many different standards, depending on its various features and capabilities.

All modems sold today support the following ITU protocols:

- ITU V.90 (modulation)
- ITU V.42 (error correction)
- ITU V.42bis (data compression)

However, earlier modems supported many industry-standard and proprietary protocols for modulation, error correction, and data compression.

Most modems today also support the proprietary Microcom Network Protocol (MNP) MNP10 and MNP10EC error-correction standards to provide better connection during conventional wired and wireless (cellular) communication sessions. The latest modems also support the newest ITU standards: V.92 (modulation) and V.44 (data compression). All current protocols are discussed later in this chapter.

Note

To learn more about earlier industry-standard and proprietary protocols, see Chapter 18 of *Upgrading and Repairing PCs, 11th Edition*, available in electronic form on the DVD-ROM packaged with this book.

Note

The term *protocol* is also used to describe software standards that must be established between different computers to allow them to communicate, such as TCP/IP.

Modems are controlled through AT commands, which are text strings sent to the modem by software to activate the modem's features. For example, the `ATDT` command followed by a telephone number causes the modem to dial that number using tone dialing mode. Applications that use modems typically generate AT commands for you, but you can control a modem directly using a communications program with a terminal mode or even the `DOS ECHO` command.

Because almost every modem uses the AT command set (originally developed by modem-maker Hayes), this compatibility is a given and should not really affect your purchasing decisions about modems. The basic modem commands might vary slightly from manufacturer to manufacturer, depending on a modem's special features, but the basic AT command set is all but universal.

Note

A list of the basic AT commands can be found in the Technical Reference on the DVD included with this book. However, the best source for the commands used by your modem is the manual that came with the device.

Although most modem users will never need to review these commands, if you use MS-DOS–based communication programs or some specialized Windows programs, you might be required to enter or edit an *initialization string*, which is a series of AT commands sent to the modem before dialing. If these commands are not correct, the modem will not work with these programs.

Bits and Baud Rates

When discussing modem transmission speeds, the terms *baud rate* and *bit rate* are often confused. Baud rate (named after a Frenchman named Emile Baudot, the inventor of the asynchronous telegraph printer) is the rate at which a signal between two devices changes in 1 second. If a signal between two modems can change frequency or phase at a rate of 300 times per second, for example, that device is said to communicate at 300 baud.

Thus, baud is a signaling rate, not a data-transmission rate. The number of bits transmitted by each baud is used to determine the actual data-transmission rate (properly expressed as bps or Kbps). Modern pure-analog (33.6Kbps and slower) modems transmit and receive more bits per baud than the original 300bps modems (which also ran at 300 baud).

Note

To learn more about bits versus baud, see Chapter 18 of *Upgrading and Repairing PCs, 11th Edition*, available in electronic form on the DVD packaged with this book.

Modulation Standards

Modems start with modulation, which is the electronic signaling method used by the modem. Modulation is a variance in some aspect of the transmitted signal. By modulating the signal using a predetermined pattern, the modem encodes the computer data and sends it to another modem that demodulates (or decodes) the signal. Modems must use the same modulation method to understand each other. Each data rate uses a different modulation method, and sometimes more than one method exists for a particular rate.

Regardless of the modulation method, all modems must perform the same task: Change the digital data used inside the computer (ON-OFF, 1-0) into the analog (variable tone and volume) data used by the telephone company's circuits, which were built over a period of years and were never intended for computer use. That's the "mo(dulate)" in modem. When the analog signal is received by the other computer, the signal is changed back from the analog waveform into digital data (see Figure 19.10). That's the "dem(odulate)" in modem.

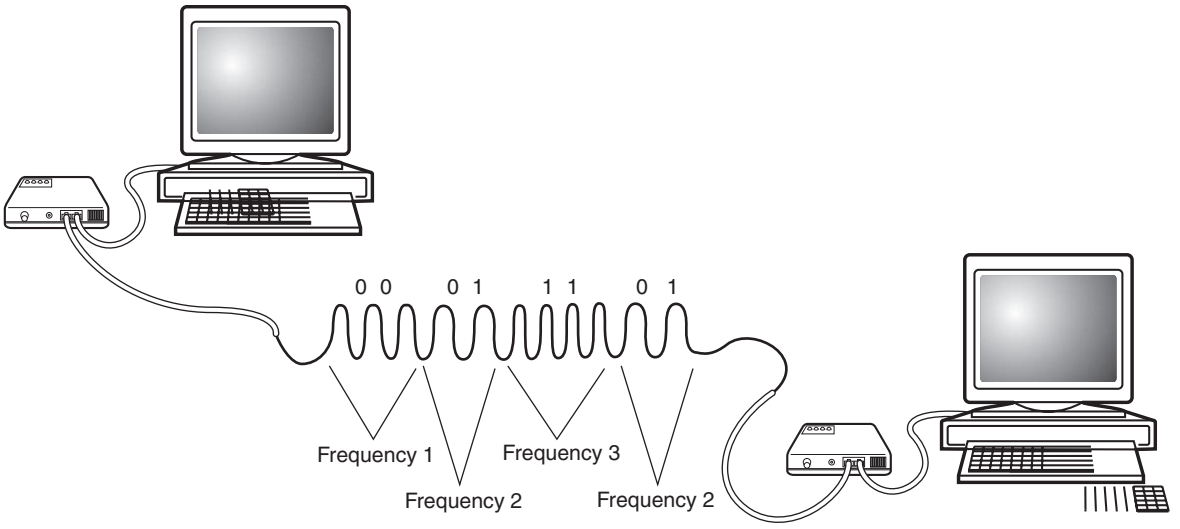

Figure 19.10 The modem at each computer changes digital (computer) signals to analog (telephone) signals when transmitting data or analog back to digital when receiving data.

The three most popular modulation methods are

- *Frequency-shift keying (FSK).* A form of frequency modulation, otherwise known as FM. By causing and monitoring frequency changes in a signal sent over the phone line, two modems can send information.
- *Phase-shift keying (PSK).* A form of phase modulation in which the timing of the carrier signal wave is altered and the frequency stays the same.
- *Quadrature amplitude modulation (QAM).* A modulation technique that combines phase changes with signal-amplitude variations, resulting in a signal that can carry more information than the other methods.

All modem protocols since ITU V.34 (33.6Kbps maximum speed) up through the current ITU V.90 and ITU V.92 standards (56Kbps maximum speed) are full-duplex protocols. A *full-duplex* protocol is one in which communications can travel in both directions at the same time and at the same speed. A telephone call, for example, is full duplex because both parties can speak at the same time. In *half-duplex* mode, communications can travel in both directions, but only one side can transmit at a time. A radio call in which only one party can speak at a time is an example of half-duplex communications.

These protocols are automatically negotiated between your modem and the modem at the other end of the connection. Basically, the modems start with the fastest protocol common to both and work their way down to a speed/protocol combination that will work under the line conditions existing at the time of the call.

The ITU V.90 and V.92 protocols are the industry-standard protocols most commonly used today; V.92 modems also support V.90.

Note

The 56Kbps standards that represent the highest current increment in modem communication speed require a digital connection at one end and are therefore not purely analog. Other high-speed communication technologies such as ISDN and cable network connections don't perform digital-to-analog conversions, so they should not be called modems, strictly speaking.

V.90

V.90 is the ITU-T designation for a 56Kbps communication standard that reconciles the conflict between the proprietary U.S. Robotics (3Com) x2 and Rockwell K56flex modem specifications developed in 1996 and 1997. The last ISA modems manufactured by major vendors typically support V.90, as do many PC Card and PCI modems built from 1998 to 2001.

▶▶ See "56Kbps Modems," p. 1079.

V.92

V.92 is the ITU-T designation for an improved version of the V.90 standard that provides faster negotiation of the connection, call-waiting support, and faster uploading than is possible with V.90. Most PCI and PC Card modems sold by major vendors since mid-2001 to the present are V.92 compatible.

▶▶ See "56Kbps Modems," p. 1079.

V.90 and V.92 are the current communication protocols supported by ISPs; any modem you want to use today should support at least the V.90 protocol.

Error-Correction Protocols

Error correction refers to the capability of some modems to identify errors during a transmission and to automatically resend data that appears to have been damaged in transit. Although you can implement error correction using software, this places an additional burden on the computer's expansion bus and processor. By performing error correction using dedicated hardware in the modem, errors are detected and corrected before any data is passed to the computer's CPU.

As with modulation, both modems must adhere to the same standard for error correction to work. Fortunately, most modem manufacturers use the same error-correction protocols.

V.42, MNP10, and MNP10EC Error-Correction Protocols

The current error-correction protocols supported by modems include Microcom's proprietary MNP10 (developed to provide a better way to cope with changing line conditions) and MNP10EC (an enhanced version developed to enable modems to use constantly changing cellular telephone connections).

V.90 and V.92 modems (as well as some older models) also support the ITU V.42 error-correction protocol, with fallback to the MNP 4 protocol (which also includes data-compression). Because the V.42 standard includes MNP compatibility through Class 4, all MNP 4–compatible modems can establish error-controlled connections with V.42 modems.

This standard uses a protocol called Link Access Procedure for Modems (LAPM). LAPM, similar to MNP, copes with phone-line impairments by automatically retransmitting data corrupted during transmission, ensuring that only error-free data passes between the modems. V.42 is considered to be better than MNP 4 because it offers approximately a 20% higher transfer rate due to its more intelligent algorithms.

Note

For information about the MNP 1–4 protocols, see Chapter 18 of *Upgrading and Repairing PCs, 11th Edition*, included in electronic form on the DVD packaged with this book.

Data-Compression Standards

Data compression refers to a built-in capability in some modems to compress the data they're sending, thus saving time and money for modem users. Depending on the type of files the modem is sending, data can be compressed to nearly one-fourth its original size, effectively quadrupling the speed of the modem—at least in theory. This assumes that the modem has V.42bis data compression built in (true since about 1990) *and* that the data hasn't already been compressed by software. Thus, in reality, the higher throughput caused by data compression applies only to HTML and plain-text files on the Web. Graphics and Zip or EXE archives have already been compressed, as have most PDF (Adobe Acrobat Reader) files. Another factor that influences the throughput of a modem is the type of UART chip used by the serial port included in an internal modem or connected to an external modem, or the use of a USB port instead of a serial port. To learn more, see "Can Non-56Kbps Modems Achieve Throughput Speeds Above 115,200bps?" in the Technical Reference section of the DVD-ROM packaged with this book.

As with error correction, data compression can also be performed with software. Data can be compressed only once, so if you are transmitting files that are already in a compressed form, such as Zip archives, GIF or JPEG images, or Adobe Acrobat PDF files, there will be no palpable increase in speed from the modem's hardware compression. The transmission of plain-text files (such as HTML pages) and uncompressed bitmaps, however, is accelerated greatly by modem compression.

MNP5 and V.42bis

Current data-compression standards in modems include Microcom's MNP 5 and the ITU V.42bis protocols. V.42bis is a CCITT data-compression standard similar to MNP Class 5, but it provides about 35% better compression. V.42bis is not actually compatible with MNP Class 5, but nearly all V.42bis modems include the MNP 5 data-compression capability as well.

V.42bis is superior to MNP 5 because it analyzes the data first and then determines whether compression would be useful. V.42bis compresses only data that needs compression. MNP 5, on the other hand, always attempts to compress the data, which slows down throughput on previously compressed files.

To negotiate a standard connection using V.42bis, V.42 also must be present. Therefore, a modem with V.42bis data compression is assumed to include V.42 error correction. When combined, these two protocols result in an error-free connection that has the maximum data compression possible.

V.44

At the same time that the V.92 protocol was introduced by the ITU in mid-2000, a companion data-compression protocol called V.44 was also introduced by the ITU. V.44 uses a new lossless LZJH compression protocol designed by Hughes Network Systems (developers of the DirecWAY satellite broadband Internet service) to achieve performance more than 25% better than that of V.42. Data throughput with V.44 can reach rates of as much as 300Kbps, compared to 150Kbps–200Kbps with V.42bis. V.42bis was developed in the late 1980s, long before the advent of the World Wide Web, so it is not optimized for Web surfing the way V.44 is. V.44 is especially designed to optimize compression of HTML text pages.

Note

V.44 is the latest compression algorithm to be based in part on the work of mathematicians Abraham Lempel and Jakob Ziv in the late 1970s. Lempel and Ziv's work also has been used in the development of LZW (Lempel-Ziv-Welch) compression for TIFF image files, GIF compressed image files, PKZIP-compatible compression, and other data compression methods.

Proprietary Standards

In addition to the industry-standard protocols for modulation, error correction, and data compression that are generally defined and approved by the ITU-T, several protocols in these areas were invented by various companies and included in their products without any official endorsement by any standards body. Some of these protocols have been quite popular at times and became pseudo-standards of their own. The only proprietary standards that continue to enjoy widespread support are the Microcom MNP standards for error correction and data compression. Others, such as 3Com's HST, CompuCom's DIS, and Hayes' V-series, are no longer popular. For details about the MNP classes, see "MNP Classes" in the Technical Reference section of the DVD-ROM packaged with this book.

Note

For more information about older proprietary protocols, see Chapter 18 of *Upgrading and Repairing PCs, 11th Edition*, included in electronic form on this book's DVD-ROM.

56Kbps Modems

At one time, the V.34 annex speed of 33,600bps (33.6Kbps) was regarded as the absolute speed limit for asynchronous modem usage. However, starting in 1996, modem manufacturers began to produce modems that support speeds of up to 56,000bps. These so-called "56K" or "56Kbps" modems are now universal, although the methods for breaking the 33.6Kbps barrier have changed several times. To understand how this additional speed was achieved, you must consider the basic principle of modem technology—that is, the digital-to-analog conversion.

As you've learned, a traditional modem converts data from digital to analog form so it can travel over the Public Switched Telephone Network (PSTN). At the destination system, another modem converts the analog data back to its digital form. This conversion from digital to analog and back causes some speed loss. Even though the phone line is physically capable of carrying data at 56Kbps or more, the effective maximum speed because of the conversions is about 33.6Kbps. An AT&T engineer named

Claude Shannon came up with a law (Shannon's Law) stating that the maximum possible error-free data communications rate over an all-analog PSTN is approximately 35Kbps, depending on the noise present.

However, because many parts of the United States' urban telephone system is digital—being converted to analog only when signals reach the telephone company's central office (or central switch)—it's possible to "break" Shannon's Law and achieve faster download rates. You can, in some cases, omit the initial digital-to-analog conversion and send a purely digital signal over the PSTN to the recipient's CO (see Figure 19.11). Thus, only one digital-to-analog conversion is necessary, instead of two or more. The result is that you theoretically can increase the speed of the data transmission, in one direction only, beyond the 35Kbps specified by Shannon's Law—to nearly the 56Kbps speed supported by the telephone network. Prior to the new ITU V.92 standard, the transmission in the other direction was still limited to the V.34 annex maximum of 33.6Kbps. However, both the modem and the ISP must have support for the ITU V.92 standard to overcome this limitation for uploading speeds.

▶▶ See "ITU V.92 and V.44—Breaking the Upload Barrier," p. 1082, for more information on how the V.92 standard enables faster uploading.

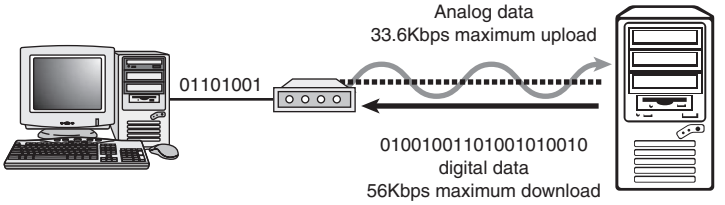

Figure 19.11 V.90-based 56Kbps connections enable you to send data at standard analog modem rates (33.6Kbps maximum) but enable you to receive data nearly twice as fast, depending on line conditions.

56Kbps Limitations

Thus, 56Kbps modems can increase data transfer speeds beyond the limits of V.34 modems, but they are subject to certain limitations. Unlike standard modem technologies, you can't buy two 56Kbps modems, install them on two computers, and achieve 56Kbps speeds. One side of the connection must use a special digital modem that connects directly to the PSTN without a digital-to-analog conversion.

Therefore, 56Kbps modems can be used at maximum speeds only to connect to ISPs or other hosting services that have invested in the necessary infrastructure to support the connection. Because the ISP has the digital connection to the PSTN, its downstream transmissions to your computer are accelerated. If both sides of the connection support standards pre-dating V.92, your communications back to the ISP are not accelerated.

On a practical level, this means you can surf the Web and download files more quickly, but if you host a Web server on your PC, your users will realize no speed gain because the upstream traffic is not accelerated unless you and your ISP both use V.92-compliant modems. If you connect to another regular modem, your connection is made at standard V.34 annex rates (33.6Kbps or less).

Also, only one digital-to-analog conversion can be in the downstream connection from the ISP to your computer. This is dictated by the nature of the physical connection to your local telephone carrier. If additional conversions are involved in your connection, 56Kbps technology will not work for you; 33.6Kbps will be your maximum possible speed.

Note

Although most advertising for 56Kbps modems refers to them as simply "56K" modems, this is inaccurate. "K" is most often used in the computer business to refer to kilobytes. If that were true, a "real" 56K modem would be downloading at 56,000 bytes per second (or 448,000 bits per second)!

With the way the telephone system has had to grow to accommodate new exchanges and devices, even neighbors down the street from each other might have different results when using a 56Kbps modem.

Caution

56Kbps modem communications are highly susceptible to slowdowns caused by line noise. Your telephone line might be perfectly adequate for voice communications and even lower-speed modem communications, but inaudible noise easily can degrade a 56Kbps connection to the point at which there is only a marginal increase over a 33.6Kbps modem, or even no increase at all. If you do have a problem with line noise, getting a surge suppressor with noise filtration might help.

Hotel connections through telephones with data jacks typically provide very slow connections with any type of modem. Even if you have a V.90- or V.92-compliant 56Kbps modem, you will be lucky to achieve even a 24Kbps transmission rate. The analog-to-digital conversions that occur between your room's telephone and the hotel's digital PBX system eliminate the possibility of using any of the 56Kbps standards the modem supports because they depend on a direct digital connection to the central switch (CS).

As an alternative, more and more hotels and motels provide Ethernet-based access to broadband Internet service. Depending on the location, you might be able to use your normal Ethernet card or connect to a USB adapter provided by the hotel. If you want high-speed Internet access as part of the package with your next hotel or motel stay, contact the specific lodging location for details and pricing.

56Kbps Standards

To achieve a high-speed connection, both modems and your ISP (or other hosting service to which you connect) must support the same 56Kbps technology. The first 56Kbps chipsets were introduced in late 1996:

- U.S. Robotics' x2 used Texas Instruments (TI) chipsets.
- Rockwell's K56flex was supported by Zoom and other modem makers.

These rival methods for achieving performance up to 56Kbps were incompatible with each other and were replaced in 1998 by the ITU's V.90 standard.

Note

For more information about K56flex and x2, see *Upgrading and Repairing PCs, 11th Edition*, available in electronic format on the DVD-ROM supplied with this book.

Unfortunately, the 56Kbps name is rather misleading, in regards to actual transmission speeds. Although all 56Kbps modems theoretically are capable of this performance on top-quality telephone lines, the power requirements for telephone lines specified in the FCC's Part 68 regulation limit the top speed of these modems to 53Kbps. The FCC has been considering lifting this speed limitation since the fall of 1998, but it still applies to modems as of early 2002.

V.90

V.90 was introduced on February 5, 1998, and was ratified by the ITU-T on September 15, 1998. Its ratification ended the K56flex/x2 standards "war": Shortly thereafter, most modem manufacturers announced upgrade options for users of x2 and K56flex modems to enable these products to become V.90 compliant.

Many modem vendors offer upgrades for K56flex and x2 modems to the V.90 standard. If you purchased your modem before the V.90 standard became official, see your modem vendor's Web site for information about upgrading to V.90.

ITU V.92 and V.44—Breaking the Upload Barrier

56Kbps protocols, such as the early proprietary x2 and K56flex and the ITU V.90 standard, increased the download speed from its previous maximum of 33.6Kbps to 56Kbps. However, upload speeds, which affect how quickly you can send email, page requests, and file transfers, were not affected by the development of 56Kbps technologies. Upload speeds with any of these 56Kbps technologies are limited to a maximum of 33.6Kbps. This causes severe speed lags for both pure dial-up users and those who depend on analog modems for upstream traffic, such as users of one-way broadband solutions—for example, one-way (Telco Return) cable modems, One-way DirecWAY, and one-way (Telco Return) fixed-base wireless Internet services. Other shortcomings of existing 56Kbps technology include the amount of time it takes the user's modem to negotiate its connection with the remote modem and the lack of uniform support for call-waiting features.

In mid-2000, the ITU unveiled a multifaceted solution to the problem of slow connections and uploads: the V.92 and V.44 protocols (V.92 was previously referred to as V.90 Plus).

V.92, as the name implies, is a successor to the V.90 protocol, and any modem that supports V.92 also supports V.90. V.92 doesn't increase the download speed beyond the 56Kbps barrier, but offers these major features:

- *QuickConnect.* QuickConnect cuts the amount of time needed to make a connection by storing telephone line characteristics and using the stored information whenever the same phone line is used again. For users who connect to the Internet more than once from the same location, the amount of time the modem beeps and buzzes to make the connection will drop from as much as 27 seconds to about half that time. Bear in mind, though, that this reduction in connection time does not come about until after the initial connection at that location is made and its characteristics are stored for future use.
- *Modem-on-Hold.* The Modem-on-Hold feature allows the user to pick up incoming calls and talk for a longer amount of time than the few seconds allowed by current proprietary call-waiting modems. Modem-on-Hold enables the ISP to control how long you can take a voice call while online without interrupting the modem connection; the minimum amount of time supported is 10 seconds, but longer amounts of time (up to unlimited!) are also supported by this feature. Modem-on-Hold also allows you to make an outgoing call without hanging up the modem connection. Modem-on-hold, similar to previous proprietary solutions, requires that you have the call-waiting feature enabled on your telephone line and also requires that your ISP support this feature of V.92.

Note

Although Modem-on-Hold is good for the Internet user with only one phone line (because it allows a single line to handle incoming as well as outgoing calls), it's not as good for ISPs because when you place your Internet connection on hold, the ISP's modem is not capable of taking other calls. ISPs that support Modem-on-Hold might need to add more modems

to maintain their quality of service if this feature is enabled. More modems are necessary because the ISP won't be able to count on users dropping their Internet connections to make or receive voice calls when Modem-on-Hold is available.

- *PCM Upstream.* PCM Upstream breaks the 33.6Kbps upload barrier, boosting upload speed to a maximum of 48Kbps. Unfortunately, because of power issues, enabling PCM Upstream can reduce your downstream (download) speed by 1.3Kbps–2.7Kbps or more. PCM Upstream is an optional feature of V.92, and ISPs who support V.92 connections might not support this feature.

Modems that support V.92 typically also support the new V.44 data-compression standard. V.44, which replaces V.42bis, provides for compression of data at rates up to 6:1—that's more than 25% better than V.42bis. This enables V.92/V.44 modems to download pages significantly faster than V.90/V.42bis modems can at the same connection speed.

When will you be able to enjoy the benefits of V.92/V.44? Although most major modem vendors have been offering V.92/V.44-compliant modems since late 2000, ISP interest in this standard has been tepid. Only one national ISP, Navipath (which provided support for many local and regional ISPs), offered V.92 access in 2001, and Navipath went out of business in September 2001. Prodigy began to offer V.92 service early in 2002.

According to the V.92 News & Updates page at Richard Gamberg's Modemsite (`www.modemsite/56K/v92s.htm`), many vendors of ISP equipment continue to drag their feet on V.92/V.44 support, in part because it often requires expensive upgrades to terminal equipment. Even after upgrading to support V.92/V.44, some existing terminal hardware is incapable of working with the desirable PCM Upstream feature. Additionally, many major modem vendors have produced so-called "V.92" modems that don't support major V.92 features. Check user reviews available at the Modemsite Web site and others before you buy a particular V.92 modem model.

Tip

Wondering whether it's time to get a V.92/V.44 modem? Before you update your current model or buy a new modem, do the following:

- Contact your ISP to see whether (or when) it plans to support V.92/V.44 and to determine which features will be supported.
- Check the V.92 ISPs listing at `www.modemsite.com/56k/v92isp.htm`. (This list also provides details about which vendors support V.44 and the upstream PCM feature of V.92.)

Although the change from x2/K56flex to V.90 was a no-cost one for many modem owners, the upgrade from V.90 to V.92/V.44 won't be as painless. In many cases, only the most recent V.90 modems will be eligible for a free upgrade to V.92/V.44 firmware. Contact your modem vendor for details.

Can your existing V.90-compatible modem be upgraded to V.92/V.44? As with earlier 56Kbps modem standards, the answer will likely be, "It depends." Some Lucent LT Winmodem (Agere Systems) modem drivers for V.90 also might include V.92 commands; see Modemsite's Lucent modem section for the latest information (`http://www.modemsite.com/56k/ltwin.asp`). For modems based on other chipsets, check with your modem vendor.

As with earlier 56Kbps standards, you shouldn't worry about V.92/V.44 support until your ISP announces that it is supporting these standards. Because the V.92 standard has several components, find out which features of V.92 your ISP is planning to support before you look into a modem firmware update or modem replacement.

Fax Modem Standards

Even though the first experimental facsimile equipment was developed at the end of World War II, it took many years for faxing to become commonplace. Similarly, the first fax boards for computers were not introduced until the late 1980s as separate devices. Later, fax capabilities were incorporated into modems. Today, virtually all modems also meet the ITU-T Class 3 fax standards, enabling them to send data to and receive data from other ITU-T Class 3 fax machines and multifunction devices.

Many recent multifunction devices also support the newer ITU-T.30E recommendation for color faxing. Fax modems don't meet this standard as shipped from the manufacturer, but you can download free color fax software developed by HP (Impact ColorFax) that works with most fax modems. Find Impact ColorFax at the BlackICE Software Web site (`www.blackice.com`).

For more information about ITU-T fax protocols, see, "ITU-T Fax Protocols" in the Technical Reference on the DVD packaged with this book.

Analog Modem Recommendations

An analog modem for a PC can take the form either of an external device with its own power supply that plugs into a PC's serial port or USB port or of an internal expansion card you insert into a PCI, an ISA, or a PC Card bus slot inside the computer. Most manufacturers of modems have both internal and external versions of the same models.

External versions are slightly more expensive because they include a separate case and power supply and sometimes require you to buy a serial modem cable or USB cable. Both internal and external modems are equally functional, however, and the decision as to which type to use should typically depend on whether you have a free bus slot or serial port, whether you have USB ports and Windows 98/Me/2000, how much room you have on your desk, the capabilities of your system's internal power supply, and how comfortable you are with opening up your computer.

I often prefer external modems because of the visual feedback they provide through indicator lights. These lights let you easily see whether the modem is still connected and transmitting or receiving data. However, some communication programs today include onscreen simulations of the lights, providing the same information.

In other situations, however, an internal modem is preferable. If you are using an older computer whose serial ports do not have buffered UART chips, such as the 16550, many internal modems include an onboard 16550 UART-equivalent chip. This onboard UART with the modem saves you the trouble of upgrading the UART serial port. Also, external 56Kbps modems can be hampered from achieving their full speeds by the limitations of the computer's serial port. An external USB model or an internal model using the PCI slot might be preferable instead. Use Table 19.4 to see how internal and external units compare.

Table 19.4 External Versus Internal Modems

Features	External	Internal
Built-in 16550 UART or higher	No (uses computer's USB port or serial port UART).	Yes (if 14.4Kbps or faster).
Price comparison	Higher.	Lower.
Extras to buy	RS-232 Modem Interface cable or USB cable in some cases.	Nothing.

Table 19.4 Continued

Features	External	Internal
Ease of moving to another computer	Easy—unplug the cables and go! USB modems require a functioning USB port on the computer and Windows 98 or above.[1] RS-232 serial modems require you to shut down the computer first before disconnecting or reconnecting the modem; USB modems can be hot-swapped.	Difficult—must open case and remove card, open other PC's case and insert card.
Power supply	Plugs into wall ("brick" type)	None—powered by host PC.
Reset if modem hangs	Turn modem off, and then on again.	Restart computer.
Monitoring operation	Easy—external signal lights.	Difficult—unless your communication software simulates the signal lights.
Interface type	RS-232 serial or USB port; some models support both types of connections. (Parallel-port modems were made a few years ago, but never proved popular and have been discontinued).	PCI or ISA; PCI is preferred for its extra speed, capability to allow mapping of COM 3 and COM 4 to unique IRQs instead of COM 1/3 and COM 2/4 sharing IRQs, and capability to work in so-called "legacy-free" systems that no longer include any ISA slots.

1. *Although late versions of Windows 95 OSR 2.x have USB support, many USB devices actually require Windows 98 or better. Use Windows 98/Me/2000/XP to achieve more reliable support for USB devices.*

◀◀ See "UARTs," p. 979.

Not all modems that function at the same speed have the same functionality. Many modem manufacturers produce modems running at the same speed but with different feature sets at different price points. The more expensive modems usually support advanced features, such as distinctive ring support, caller ID, voice and data, video teleconferencing, and call-waiting support. When purchasing a modem, be sure it supports all the features you need. You also should make sure the software you plan to use, including the operating system, has been certified for use with the modem you select.

If you live in a rural area, or in an older city neighborhood, your telephone line quality might influence your decision. Look at comparison test results carefully and pay particular attention to how well various modems perform with noisy lines. If your phone line sounds crackly during a rainstorm, that poor-quality line makes reliable modem communications difficult, too, and it can limit your ability to connect at speeds above 33.6Kbps.

Another feature to consider is the modem's resistance to electrical damage. Some brands feature built-in power protection to shield against damage from digital telephone lines (higher powered and not compatible with modems) or power surges. However, every modem should be used with a surge protector that allows you to route the RJ-11 telephone cable through the unit for protection against high-voltage surges.

All modems on the market today support V.90 or V.92, and even if your particular location can't support those speeds, your modem might still offer advanced features, such as voicemail or simultaneous voice and data. Keep in mind that V.90/V.92 connections seem to work better for many users if their

modems also support x2. If you prefer a modem made by a vendor that also supports K56flex, try to buy a modem that contains both types of standards in its firmware (referred to by some vendors as "Dualmode" modems).

Choosing to Upgrade

If you bought your modem in 1997 or later, or if it was included in your computer, chances are good that it came with 56Kbps support or that you've upgraded it to some form of 56Kbps support. However, even though today's V.90/V.92 modems still have the same maximum speed, other changes in modem design have occurred that might make a modem upgrade desirable for you. And if you are still using a 33.6Kbps modem or even slower model, you should get a 56Kbps modem if your line quality can support it.

Table 19.5 summarizes some of the major changes in analog modem design and features in recent years, along with advice on who should consider these features.

Analog modems introduced in 2001 and 2002 still run at the 53Kbps FCC maximum with the potential to run at up to 56Kbps if the FCC regulations change, but they might offer one or more of the following advanced features:

- Call-waiting support
- PCI expansion slot for internal modems
- USB connection for external modems
- Faster performance for gaming
- MNP10 and MNP10EC
- V.92/V.44 support

Table 19.5 Analog Modem Features and Types

Modem Feature	Benefit	Who Should Buy	Cautions
MNP10EC support	Improves performance on poor-quality phone lines by quickly adjusting line speed up and down with changing conditions.	Anyone with poor-quality lines, especially if modem at other end also has MNP10EC support; users who want to use modem with cellular phones.	Don't buy MNP10 support by mistake; MNP10EC is much better and includes MNP10. Check with ISP to see whether cellular connections are supported; speed of such connections can be 14.4Kbps or slower.
PCI bus	Works in PCI slots that dominate current systems and have replaced ISA slots. PCI modems can share IRQs with other devices and be redirected to open IRQs.	Anyone without ISA slots or who is planning to move the modem to another computer in the future and prefers internal modems.	Verify one or more PCI slots are available; look for other features listed here to make change as useful as possible; see also "Software Modems (WinModems)" later in this chapter.

Table 19.5 Continued

Modem Feature	Benefit	Who Should Buy	Cautions
USB connection	Works with USB connectors on most current and all future computers; high-speed connection and capability to connect many devices via a hub.	Anyone who wants portability and has USB connectors along with Windows 98 or above.	Although Windows 95 OSR 2.5 (Win95″C″) has USB support, many devices require Win98 or better; make sure USB ports have been activated in BIOS.
Gaming-optimized modem	Faster PING and response for gaming, which is more important than data throughput.	Anyone who plays a lot of online games or wants to get started.	Game optimizations are not useful for ordinary Web surfing. These modems are more expensive than others.
Call-waiting support	Allows you to answer the phone and not lose the modem connection, instead of disabling call-waiting, which most modems require.	Anyone who uses call-waiting and doesn't like voice callers to get busy signals; check with manufacturer to see whether your existing modem can be upgraded with a driver.	Maximum talk time might be only a few seconds; make sure you have the phone near the computer for fast "hello, I'll call you later" answers to avoid exceeding time limit.
V.92/V.44 support	Faster uploads, connection negotiation, Modem-on-hold, better throughput on downloads.	Anyone whose ISP supports features.	Check with your ISP to see whether faster will be introduced and to see whether all features will be supported.
Voice support	Allows digitizing of received calls; computerized answering machine and faxback; inbound and outbound phone calls via computer.	Anyone who wants to use PC as a telecommunications center.	Check quality of voice recording; can use up a lot of disk space.

Software Modems (WinModems)

Software modems, sometimes referred to as *WinModems* after the pioneering U.S. Robotics version, can save you money at purchase time but can cause problems with speed and operating-system compatibility later.

For users looking for an inexpensive internal modem, a software modem using Windows instead of a UART-equipped internal or external modem looks like a great deal, often costing less than $40. But, there is no free lunch for modem users. What can you lose with a "soft modem"?

First, you need to realize that there are actually two types of software modems (broadband): those that rely on Windows and the CPU for all operations (these modems are also called *controllerless* modems) and those that use a programmable digital signal processor (DSP) chip to replace the UART. Both types of modems use less power than traditional UART-based modems, making them better for use with notebook computers. Although both are "software modems," there's an enormous difference in what you're getting.

A Windows-based modem must run under Windows because Windows provides the brains of the modem, a cost-cutting move similar to that used by some low-cost host-based printers. You should avoid this if you're planning to try Linux, move the modem to a Macintosh, or use an old MS-DOS–based communications program. If you have no drivers for your modem/operating system combination, you'll have no luck using the software modem.

Software modems that lack a DSP have a second major strike against them: They make your CPU do all the work. Although today's computers have much faster CPUs than those required for typical software modems (Pentium 133 minimum), your modem can still slow down your computer if you multitask while downloading or surfing the Web.

Most of the modems bundled with computer systems are software modems, and the major chipsets used include Lucent LT (now Agere Systems), Conexant (formerly Rockwell) HCF, U.S. Robotics WinModem, ESS Technology's HSP-compliant chipsets, Intel's Modem Silicon Operation (formerly Ambient), and PCTel.

Except for U.S. Robotics, the other companies produce chipsets that can be found in the modems made by many manufacturers.

For best results, do the following:

- *Make sure your software modem uses a DSP.* Typically, these modems don't require a particular CPU or a particular speed of CPU.
- *Consider modems built around the Lucent/Agere LT chipset.* These modems have a DSP, and Lucent/Agere's firmware is frequently revised to achieve the best results in a rapidly changing telephony environment.
- *Use the modem manufacturer's own drivers first.* But software modems can often use any manufacturer's drivers for the same chipset with excellent results; in particular, Lucent/Agere LT chipset modems typically can use any Lucent/Agere LT driver from any modem manufacturer.
- *Don't delete the old software driver when you download and install new modem software.* As with UART-equipped modems, the latest firmware isn't always the best.
- *Look carefully at the CPU, RAM, and operating system requirements before you buy your modem.*

Tip

Many manufacturers sell both hardware-based and software modems. If you have an older system or want the option to use MS-DOS– or Linux-based communications programs, the hardware modem with a traditional UART might cost more but be a better choice.

Finding Support for "Brand-X" Modems

Many computer users today didn't install their modems, or even purchase them as a separate unit. Their modems came bundled inside the computer and often have a bare-bones manual that makes no mention of the modem's origin or where to get help. Getting V.90 firmware updates, drivers, or even jumper settings for OEM modems such as this can be difficult.

One of the best Web sites for getting help when you don't know where to start is `http://www.windrivers.com`, which features a modem identification page with the following features:

- FCC ID: Enter the FCC ID number attached to the internal or external modem to determine who made it. Look on the bottom of an external modem or open the case and look on the side of the internal modem to find this number.

- Lookup by chipset manufacturer.
- Modem throughput tests.
- Links to major modem manufacturers.

Squeezing Performance from Your 56Kbps Modem

Although many users of 56Kbps modems have seen significant improvements in their connect speeds and throughputs over their previous V.34-type modems, many have not or have seen only sporadic improvements. According to the research of Richard Gamberg, available online at his Modemsite Web site (`http://www.modemsite.com`), a combination of five factors comes into play to affect your ability to get reliable connections in the range of 45Kbps–53Kbps (the current FCC maximum):

- The modem
- The modem firmware/driver
- Your line conditions
- The ISP's modems
- The ISP's modem firmware

It's up to you to ensure that you match your modem 56Kbps type to the 56Kbps standards your ISP supports, and that you use the best (not always the latest!) modem firmware and drivers, as discussed in the previous section.

Other modem adjustments recommended by Modemsite include

- Modifying existing modem .INF files used by Windows 9x to accurately reflect connection speed
- Disabling 56Kbps connections (!) when playing games to minimize lag times

Note

This last suggestion might seem odd, but "fast" modems are designed to push a large amount of data through for downloads, and gameplay over modems actually deals with small amounts of data instead. The lag time caused by 56Kbps data handling can make a regular "fast" modem seem slow. If you want a fast modem for both downloading and game playing, see "Choosing to Upgrade," earlier in this chapter.

The site also hosts a forum area for discussing modem configuration, reliability, and performance issues.

Telco "Upgrades" and Your Modem

In addition to the well-known analog-to-digital conversion issue that prevents some phone lines from handling 56Kbps modems at anything beyond 33.6Kbps, other local telephone company (telco) practices and services can either prevent 56Kbps from ever working or take it away from you after you've enjoyed it for a while.

If you were getting 45Kbps or faster connections with your 56Kbps modem but can no longer get past 33.6Kbps, what happened? Some local telephone companies have been performing network "upgrades" that improve capacity for voice calls but prevent 56Kbps modems from running faster than 28Kbps. The cause seems to be the telephone companies' change from a signaling type called RBS (Robbed Bit Signaling) to SS7 (Signaling System 7), which changes how data used by the modem

for high-speed access is detected. Caller ID devices connected to your phone line use RBS or SS7 signals to obtain information from incoming phone calls. If you use a caller ID box on the same phone circuit as your modem (even if it's connected in another room), you might not be able to get fast connections, or you might experience frequent disconnects. If you notice a drop in connection speed or reliability after you install caller ID, disconnect the caller ID box from the wall jack while you're online and see whether the speed and reliability of your modem connections improve.

What else can you do? You can install the latest firmware available for your modem model or chipset. You can also check with your local telephone company to see whether it can update its firmware to solve the problem. Even if your modem has different firmware, checking on an upgrade might still be useful because this problem is likely to become widespread as telephone numbers, exchanges, and area codes continue to multiply like weeds and telephone network upgrades must keep pace.

Sharing Your Internet Connection

Whether you have a 56Kbps dial-up modem or a broadband connection, one connection is often not enough for a home or small-office setting. You can share your connection with other computer users with one of the following methods:

- *Computer-based sharing solutions.* These work by connecting the computer with Internet access to a network with the other computers with which you want to share the connection. The computer with the connection acts as a gateway to the Internet.
- *Router-based sharing solutions.* These work by connecting all the computers on a network with a router or gateway connected to the Internet. Most routers are designed to work with broadband devices that use a USB or 10BASE-T connection, but a few work with analog modems.

Typical computer-based sharing solutions include

- *Microsoft Internet Connection Sharing (ICS).* Introduced in Windows 98 Second Edition (Win98SE) and also a part of Windows Me, Windows 2000, and Windows XP
- *Third-party gateway or proxy-server programs such as Wingate, Winproxy, and others*

Both ICS and third-party programs can also work with non-Windows computers because the TCP/IP network protocol, the standard protocol of the Internet, is used for networking.

▶▶ See "Network Protocols: Ethernet Versus Token-Ring," p. 1108, for details of the TCP/IP protocol.

Router-based solutions are available for popular types of home and small-office networks, including

- 10BASE-T and 10/100 Ethernet
- IEEE 802.11a and 802.11b wireless Ethernet
- HomePNA (phone-line) and HomeRF (wireless) networks

Comparing Gateways, Proxy Servers, and Routers

To the typical user, it doesn't matter whether a gateway, proxy server, or router is used to provide shared Internet access. Traditional gateway programs such as Microsoft ICS, Sygate Home Network, and WinGate use a method of shared access called Network Address Translation (NAT), which enables sharing by converting network addresses into Internet-compatible addresses during the file request and download process. This process requires little client PC configuration but doesn't permit page caching, content filtration, firewalls, or other useful services that can be provided by a proxy server. Proxy servers traditionally have required tricky configuration—sometimes at an individual application level. However, products such as WinProxy combine the ease of configuration of a gateway with the extra features of a proxy server.

Popular third-party sharing programs include WinProxy (www.winproxy.com), WinGate (www.wingate.com), and Sybergen SyGate (www.sybergen.com). Many home-oriented networks and modems are bundled with these or similar products, so if you're in the market for a new modem or are building a small network, ask whether a proxy server or gateway program for Internet sharing is included. If not, you can download free trial versions from the previously listed Web sites.

If you don't like leaving a computer on at all times to provide Internet access to the network, a router is the only way to go. Routers also provide better firewall protection for all computers on the network, and some, such as certain Linksys models, can be configured to require networked PCs to be running specified firewall or antivirus software before Internet access is granted. The most common routers for broadband Internet access also contain a switch, so you won't need a separate connection device for your home network.

Microsoft Internet Connection Sharing

Windows 98 Second Edition, Windows Me, Windows 2000, and Windows XP feature a built-in gateway program called Internet Connection Sharing (ICS), which allows users to share a single Internet connection—either dial-up or broadband. Because ICS is a gateway and clients use TCP/IP networking to use the gateway, only the gateway computer needs to use Windows 98 SE, Windows Me, or Windows 2000. Any computer using TCP/IP with the option to set up a gateway can be used as a client, including computers using older versions of Windows 9x and other operating systems.

Requirements for ICS

ICS requires a network interface card (NIC) to be installed in the host computer and a network connection to each guest computer to share the host's Internet connection.

If the Internet connection is made through a NIC (as is the case with DSL, two-way cable modems, or fixed wireless broadband connections), two NICs are required: one for the Internet connection and one for sharing the connection. If you want to use a computer with limited expansion slot space inside as the ICS gateway, you might be able to connect to a broadband Internet device or to your favorite network solution with a USB port.

ICS requires special configurations or might not work with some one-way services that use an analog modem (such as some cable modem, fixed wireless, or DirecWAY versions) because these devices use a separate connection for downloading and uploading.

Figure 19.12 shows a typical home network using ICS to share a cable modem.

Overview of the ICS Configuration Process

The configuration process has two parts:

- Installing ICS on the gateway computer
- Configuring the clients to use the ICS gateway to reach the Internet

The process of installing ICS on the gateway computer varies with the Windows version:

- For Windows 98SE and Windows Me, install ICS through the Add/Remove Programs icon in Control Panel as a Windows component.
- For Windows 2000 and Windows XP, ICS is built into the Network icon in Control Panel.

If you need to install a network interface card or device before you can share your Internet connection, you must do this before you can configure ICS on the gateway computer.

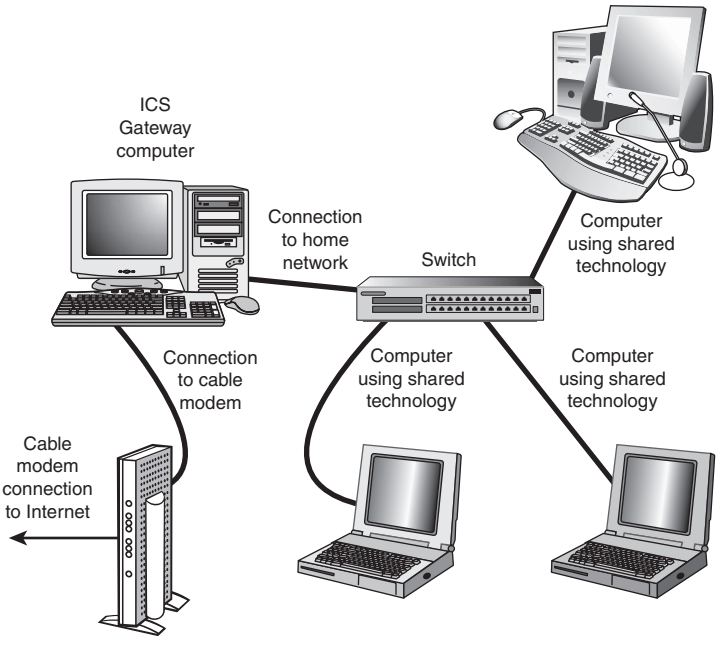

Figure 19.12 When ICS is used to share a cable modem, you might need two network connections. This computer has a built-in network port (attached to the cable modem), so the user must add another network card to connect to the home network.

Configuring ICS on the Gateway Computer with Windows 98SE and Windows Me

If ICS was not installed when Windows was installed, install it by selecting Start, Settings, Add/Remove Programs, Windows Setup. Select ICS from the Internet Tools category; Windows Me includes ICS as part of its Home Networking Wizard.

Next, specify whether you are using a dial-up connection (modem or ISDN) or a high-speed connection (LAN, including cable modem or DSL).

If you select dial-up, choose the dial-up connection (which must be set up already) you'll be sharing, followed by the NIC that connects you with the client PCs that will share the connection. Windows creates a client configuration floppy and prompts you to reboot the computer.

When you view the Network Configuration in the Control Panel after rebooting, you should see the following:

- Three adapters (your actual NIC, the dial-up adapter, and a new one called Internet Connection Sharing)
- Three Internet Connection Sharing protocol entries, listing the adapters mentioned earlier in the chapter
- Three TCP/IP protocol entries, listing the adapters mentioned earlier in the chapter

The TCP/IP protocol entry for Home must point to the NIC that connects the clients to the host PC; the TCP/IP protocol entry called Shared must point to Dial-Up Networking; and the remaining TCP/IP protocol entry must point to Internet Connection Sharing.

Also, check the TCP/IP configuration for Home (the NIC) and verify the IP address; it should be 192.168.0.1. This IP address might need to be provided to the computers that will share the Internet connection. If the settings aren't correct, remove ICS and start over. Start an Internet connection on the gateway (host) computer before continuing.

Tip

For a more detailed description of setting up ICS and networking on a computer running Windows 98SE, see *Special Edition Using Microsoft Windows 98 Second Edition* by Ed Bott and Ron Person (Que, 2000).

For a more detailed description of setting up ICS and networking on a computer running Windows Me, see *Special Edition Using Microsoft Windows Me* by Ed Bott (Que, 2000).

Configuring ICS on the Gateway Computer with Windows 2000 and Windows XP

If you want to share a dial-up analog modem or ISDN connection with Windows 2000, look for the ICS tab on the properties sheet for the connection in the Network and Dial-up Connections folder. Enable ICS and enable On-Demand Dialing (which will allow anyone on the network to open a connection as necessary). You also must enable the Remote Access Auto Connection Manager service in the Computer Management Control Panel. Configure this service to run Automatically.

If you want to share a broadband connection with Windows 2000, look for the Sharing tab in the properties sheet for the connection to your broadband Internet device in the Network and Dial-up Connections folder. Enable sharing.

Tip

For a more detailed description of setting up ICS and networking on a computer running Windows 2000, see *Special Edition Using Microsoft Windows 2000 Professional* by Robert Cowart and Brian Knittel (Que, 2000).

Windows XP uses the Set Up a Home or Small Office Network Wizard available in the My Network Places folder to configure ICS for both the ICS gateway and client computers. You can also configure ICS manually through the properties sheet for your connection in the My Network Places folder.

Tip

For a more detailed description of setting up ICS and networking on a computer running Windows XP, see *Special Edition Using Microsoft Windows XP Home Edition* (Que, 2002) or *Special Edition Using Microsoft Windows XP Professional* (Que, 2002). Both books are coauthored by Robert Cowart and Brian Knittel.

Configuring ICS on the Client Computers

Use the ICS configuration disk created during the ICS installation process or the ICS client setup program available on the Windows CD to configure ICS on other Windows versions. If you prefer to set up ICS manually on client computers, do the following:

- Install the TCP/IP protocol on each client.
- Ensure that the following values are set up in the TCP/IP protocol for each client PC:
  - IP address: automatically obtained
  - WINS Resolution: disabled
  - Gateway: None
  - DNS: disabled
  - Each client will be assigned an IP address by the ICS server.
- Restart each client after performing the previous steps.
- Use a Web browser on each guest to verify the connection is working; Internet Explorer should not have any dial-up settings configured for it and should have no LAN settings enabled. Netscape Navigator/Communicator should be set to Direct Connection to the Internet.

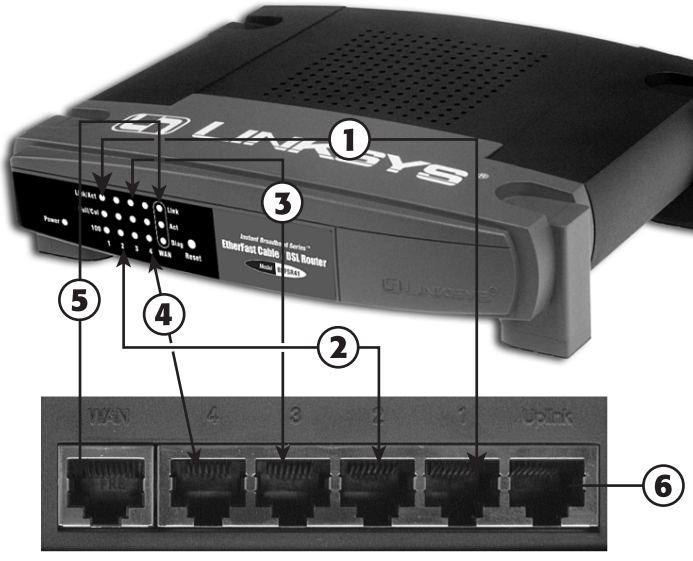
Some versions of Netscape Navigator might not work unless you create a Dial-Up Networking adapter on the guest and set its gateway, as explained earlier in the chapter.

If you are using Windows 9x or Me, reboot before you test the connection.

Note

Useful Web sites that cover this process in more detail include

- `http://www.practicallynetworked.com`
- `http://www.duxcw.com/digest/Howto/index.html`



The Practically Networked Web site also provides useful tips for sharing one-way broadband services.

Routers for Internet Sharing

Just as an ICS gateway has two IP addresses—one for the network and one for the Internet—so does a router. Most routers are sold for use with two-way broadband Internet access devices such as two-way cable modems and fixed wireless broadband services or DSL lines. Most of these devices connect to the computer via a 10BASE-T Ethernet port, as seen in Figure 19.13.

When you use a router to share your Internet connection, the WAN port on the router replaces the network card connection originally used to connect your computer with the cable modem or DSL modem. All computers on the network connect to LAN ports and can share files and printers with each other as well as share Internet access.

The router can be configured to provide either dynamically assigned or fixed IP addresses to each computer connected to it through the LAN ports and can be configured to use the same MAC address (a unique hardware address assigned to each network component) originally used by the network card first connected to the cable modem or DSL modem. This prevents the ISP from determining that you're sharing the connection. The WAN port on the router can be configured to obtain an IP address from the cable modem or DSL modem or to have a fixed IP address, depending on the configuration required by the ISP.

1. LAN port #1
2. LAN port #2
3. LAN port #3
4. LAN port #4
5. WAN port (connects to cable or DSL modem)
6. Uplink port (connects to a hub or switch to allow additional users to connect to the Internet)

Figure 19.13 Front (top) and rear (bottom) views of a typical broadband router with a built-in four-port switch, the Linksys EtherFast Cable/DSL Router, BEFSR41. *Top photo courtesy of Linksys.*

As long as the router is running and properly connected to the cable modem or DSL modem, any computer connected to it can go online just by opening its email client or Web browser.

Figure 19.14 shows a typical 10/100 Ethernet home network configuration that uses a router with a built-in switch to share a cable modem.

If you have a wireless network, connect the wireless access point or gateway device designed for your network to the cable modem or other broadband Internet device (some also work with analog modems). The wireless access point or gateway device will transfer data to and from computers on the wireless network and the Internet.

For more information about choosing and installing wired and wireless networks, see Chapter 20.

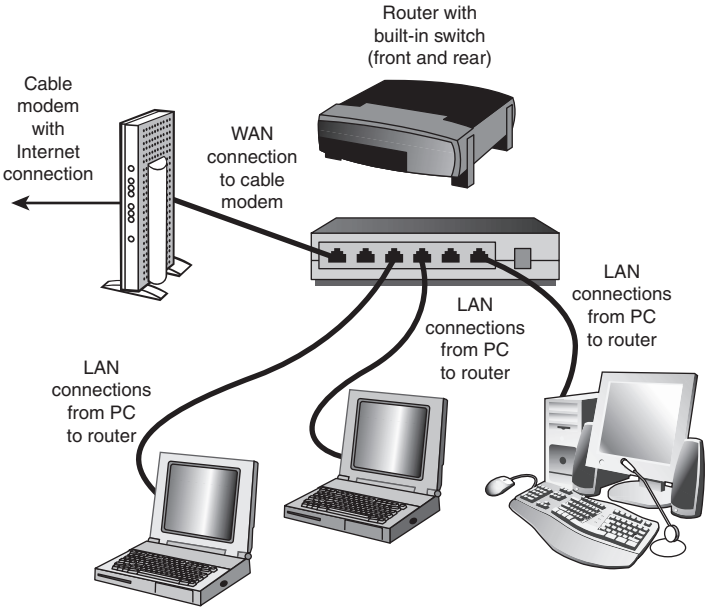


Figure 19.14 When you use a router to share a cable modem or DSL modem, you need only one network card in each computer. This router incorporates a switch that can connect up to four computers to the cable modem.

Internet Troubleshooting

This section deals with hardware problems that can cause Internet problems. Software problems usually are caused by incorrect configuration of the TCP/IP protocol required by all types of Internet connections. For more information about TCP/IP or other software problems, see Chapter 20.

Diagnosing Problems with a Shared Internet Connection

Although each Internet sharing product has individual configuration issues, the following tips provide general guidelines useful for solving problems with all of them.

Check Your Host Configuration

If your host isn't set up correctly, it can't share its connection with clients. Check the bindings for TCP/IP or other protocols used to create the shared connection. If you are using Microsoft's ICS and two Ethernet cards, you will see entries in the Network configuration on the host computer for each Ethernet card and for the ICS software itself.

Check Your Client Configuration

Make sure your clients have correct TCP/IP, DHCP, and other protocol settings for the host. The `ping` command can be used to check the Internet connection; try pinging a Web site by opening a Windows command prompt and typing a command, such as `ping www.selectsystems.com`. If you have a working Internet connection, you should see the IP address for the Web site you specify and

the round-trip time (or ping rate) for four signals sent to the Web site. If you get no response or see an error message, you might have a configuration problem with your TCP/IP configuration.

Note

Because pinging can also be used for denial-of-service (DoS) attacks by hackers on Web sites, some Web sites don't respond to pings. Use `ping` when your system is working properly to find a Web site that will respond to `ping` and use that site for troubleshooting as described previously.

Verify that the host has a working Internet connection that's active before you try to share it. Check the sharing program's documentation to see how guests can dial the host's modem to start a connection if necessary.

Speed Will Drop with Multiple Users

It's normal for the speed of an Internet connection to drop with multiple users, but if you're concerned about the degree of decline, check with the sharing software provider for Registry tweaks and other options to improve performance.

Diagnosing Connection Problems with Signal Lights

Signal lights are found on most external broadband devices, such as cable modems, wireless broadband routers, and DSL modems. The signal lights indicate whether the unit is receiving signals from the computer, sending data to the network, or receiving data from the network and whether the unit can "see" the network—even if no data is currently flowing through the unit.

On many units, the power light also is used to indicate problems. If the light is normally green, for example, a red light might indicate the unit has failed. Other lights flash when data is being sent or received. On cable modem or wireless broadband routers, look for a signal lock light; this light flashes if the unit is trying to lock onto a signal from the cable network or wireless transmitter.

Learn the meaning of the lights on your broadband device to help you diagnose problems; the user manual or vendor's Web site will provide the troubleshooting information you need for the particular broadband device you use.

Analog Modem Fails to Dial

1. Check line and phone jacks on the modem. Use the line jack to attach the modem to the telephone line. The phone jack takes the same RJ-11 silver cord cable, but it's designed to let you daisy-chain a telephone to your modem, so you need only a single line for modem and telephone use. If you have reversed these cables, you will not get a dial tone.
2. If the cables are attached properly, check the cable for cuts or breaks. The outer jacket used on RJ-11 telephone cables is minimal. If the cable looks bad, replace it.
3. If the modem is external, make sure the RS-232 modem cable is running from the modem to a working serial port on your computer and that it is switched on. Signal lights on the front of the modem can be used to determine whether the modem is on and whether it is responding to dialing commands.
4. If the modem is a PC Card (PCMCIA card), make sure it is fully plugged into the PCMCIA/PC slot. With Windows 9x/Me/2000/XP, you should see a small PCMCIA/PC Card icon on the toolbar. Double-click it to view the cards that are currently connected. If your modem is properly attached, it should be visible. Otherwise, remove it, reinsert it into the PCMCIA/PC Card slot, and see whether the computer detects it.

Connecting a PC Card Modem via a Dongle

Most PC Card modems do not use a standard RJ-11 cable because the card is too thin. Instead, they use a connection called a *dongle*, which runs from the PC Card to the telephone. If this proprietary cable is damaged, your modem is useless. You should purchase a spare from the modem vendor and carry it with you. And if you find the dongle is too short to reach the data jacks in a hotel room, buy a coupler from your local RadioShack or telephone-parts department and attach a standard RJ-11 cable to your dongle via the coupler. Dongles are also used with most PC Card network cards for the same reason; the RJ-45 twisted-pair cable connector is too wide to attach to many PC Cards.

5. Make sure your modem has been properly configured by your OS. With Windows 9x/Me/2000, use the Modems control panel to view and test your modem configuration (with Windows XP, you can use the Modem Troubleshooter). Select your modem and click the Diagnostics tab. This displays the COM (serial) ports in your computer. Select the COM port used by the modem, and click the More Info tab. This sends test signals to your modem. A properly working modem responds with information about the port and modem.
6. If you get a `Couldn't Open Port` error message, your modem isn't connected properly. It might be in use already, or there might be an IRQ or I/O port address conflict with another card in your computer. Whether you have a modem installed, every COM port that is working will display its IRQ, I/O port address, and UART chip type when you run Diagnostic. The UART type should be 16550 or above for use with any modern modem.

Note

You can also test your modem response by setting up a HyperTerminal session (discussed earlier) to send the modem commands. If the modem fails to respond, this is another indication of a problem with the modem-PC connection.

Computer Locks Up After Installing or Using Internal Modem, Terminal Adapter, or Network Card

The usual cause of lockups after you install an internal card is an IRQ conflict. Internal analog modems that use ISA slots typically cause the "curse of the shared IRQ."

COM 3 shares IRQ 4 with COM 1, and COM 4 shares IRQ 3 with COM 2 by default. The problem is that IRQ sharing for ISA devices (such as your COM ports) works when only one device at a time is using the IRQ. The most likely cause for your problem is that your mouse is connected to COM 1, your internal modem is using COM 3, and both COM ports are using the default IRQ of 4. There is no problem as long as the mouse has IRQ 4 all to itself, but the moment you try to use the modem, the computer can't handle two devices trying to use IRQ 4 and locks up. The only solution is to get the internal modem and mouse working on *separate*, non-conflicting IRQs. You have two options: Move the mouse to another port, or disable COM 2 in your computer to make room for an internal modem on COM 2.

ISA network cards and internal ISDN terminal adapters also can cause conflicts with either serial ports or other devices using IRQs.

You can minimize or eliminate IRQ conflicts by using PCI modems, network cards, and terminal adapters or by using external USB versions when available. With Windows 95 OSR 2.x, Windows 98, Windows Me, Windows 2000, and Windows XP, IRQ steering features supported by most newer Pentium-class chipsets allow multiple PCI-based devices to use the same IRQ without any problems.

Move the Mouse to Another Port

If you're still using a serial mouse, you should consider switching to a PS/2 mouse (which uses IRQ 12) or a USB mouse to avoid serial port conflicts with analog modems. If your system has no PS/2 mouse port or USB port, consider using the mouse on COM 2 instead of COM 1 and installing an analog modem as COM 1.

If your system uses Windows 98/Me/2000/XP but doesn't have a USB port, you can add a PCI card with USB ports for less than $30, enabling you to connect a USB mouse or other USB peripherals.

Disable COM 2

COM 2, the second serial port, is found on the motherboard of most Pentium-class PCs. If you are using an ISA modem, you should disable COM 2 on the motherboard to allow the modem to use COM 2.

To disable it, go into your computer's BIOS setup program, look for the screen that controls built-in ports (such as Onboard Peripherals), and disable the port. Save the changes and exit the setup program, and the system reboots. To see whether COM 2 is disabled, use the Windows 9x/Me/2000 System Properties sheet Device Manager. Then set your modem for COM 2, IRQ 3, and install it.

Computer Can't Detect External Modem

1. Make sure the modem has been connected to the computer with the correct type of cable.

   For external modems that use an RS-232 serial port, you might need a separate RS-232 modem cable, which has a 9-pin connector on one end (to connect to the computer) and a 25-pin connector on the other end (to connect to the modem). Some external modems have an integrated modem cable. Because RS-232 is a very flexible standard encompassing many pinouts, be sure the cable is constructed according to the following diagram:

PC (with 9-pin COM port - male)		Modem (25-pin port - female)
3	TX data	2
2	RX data	3
7	RTS	4
8	CTS	5
6	DSR	6
5	SIG GND	7
1	CXR	8
4	DTR	20
9	RI	22

   If you purchase an RS-232 modem cable prebuilt at a store, you'll have a cable that works with your PC and your modem. However, you can use the preceding chart to build your own cable or, by using a cable tester, determine whether an existing RS-232 cable in your office is actually made for modems or some other device.

2. Make sure the COM (serial) port or USB port to which the modem is connected is working.

   The Windows 9x/Me/2000/XP diagnostics test listed earlier can be useful in testing the serial port, but third-party testing programs—such as Touchstone Software's CheckIt, AMIDIAG, and many others—have more thorough methods for testing the system's COM ports. These programs can use loopback plugs to test the serial ports. The loopback plug loops signals that would be sent to the modem or other serial device back to the serial port. These programs normally work best when run from the MS-DOS prompt.

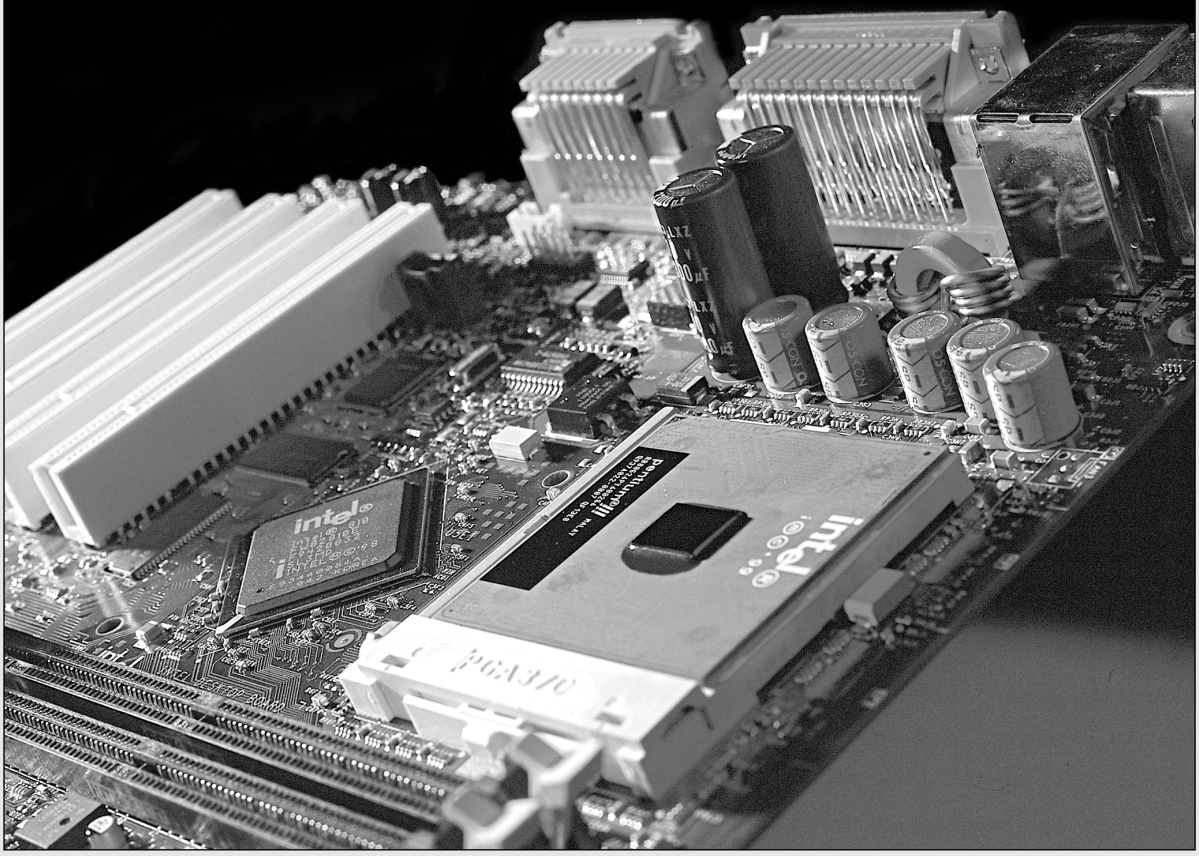
   SmithMicro's CheckIt Suite software includes a loopback plug to test serial ports. Loopback plugs will vary in design depending on the vendor.

   To ensure that the USB port is working, check the Device Manager in Windows; a working USB port is listed as a USB Root hub and a PCI to USB Universal Host Controller in the Universal Serial Bus device category. Any external USB hubs also are listed in the same category. If this category is not listed and the ports are physically present on the computer, make sure you are using Windows 98/Me/2000/XP (only a few late versions of Windows 95 have USB support). If you are, be sure the USB ports are enabled in the system BIOS.

3. Check the power cord and power switch.

Using Your Modem Sound to Diagnose Your Modem

If you listen to your modem when it makes a connection, you might have realized that different types of modems make distinctive connection sounds and that different connection speeds also make distinctive sounds.



The various types of 56Kbps modems have distinctly different handshakes of tones, buzzes, and warbles as they negotiate speeds with the ISP's modem. Learning what your modem sounds like when it makes a 56Kbps connection and when it settles for a V.34-speed connection can help you determine when you should hang up and try to connect at a faster speed.

The Modemsite's troubleshooting section has a number of sound samples of various modems during the handshaking process. Use RealPlayer to play the samples, available at `www.modemsite.com/56k/trouble.asp` (click the Handshakes link).

Compare these sound samples to your own modem; be sure you adjust the speaker volume for your modem so you can hear it during the call.

CHAPTER 20

Local Area Networking

Focus of This Chapter

This chapter concentrates on how to build and use a peer-to-peer network, the lowest-cost network that is still highly useful to small business and home-office users. This type of network can be created by adding network hardware to any recent version of Windows, from Windows 9x and NT through Windows Me, 2000, and XP. As you'll see, most peer-to-peer networks can be "grown" into client/server networks at a later point by adding a dedicated server and the appropriate software to the server and client PCs.

Thus, this chapter provides the hands-on and practical information you need to create a small-office, workgroup, or home-office network. If you are managing a corporate network using Linux, Unix, Windows NT Server, Windows 2000 Server, or Novell NetWare, you will also be concerned with matters such as security, user profiles, SIDs, and other factors beyond the scope of this book.

Note

Networking is an enormous topic. For more information about client/server networking, wide-area networking, the Internet, and corporate networking, I recommend *Upgrading and Repairing Networks, Third Edition*, from Que.

Defining a Network

A *network* is a group of two or more computers that *intelligently* share hardware or software devices with each other. A network can be as small and simple as two computers that share the printer and CD-ROM drive attached to one of them or as large as the world's largest network: the Internet.

Intelligently sharing means that each computer that shares resources with another computer or computers maintains control of that resource. Thus, a switchbox for sharing a single printer between two computers doesn't qualify as a network device; because the switchbox—not the computers—handles the print jobs, neither computer knows when the other one needs to print, and print jobs can interfere with each other.

A shared printer, on the other hand, can be controlled remotely and can store print jobs from different computers on the print server's hard disk. Users can change the sequence of print jobs, hold them, or cancel them. And, sharing of the device can be controlled through passwords, further differentiating it from a switchbox.

Shared Hardware Components

Virtually any storage or output device can be shared over a network, but the most common devices include

- Printers
- Disk drives
- CD-ROM and optical drives
- Modems
- Fax machines
- Tape backup units
- Scanners

Entire drives, selected folders, or individual files can be shared with other users via the network.

In addition to reducing hardware costs by sharing expensive printers and other peripherals among multiple users, networks provide additional benefits to users:

- Multiple users can share access to software and data files.
- Electronic mail (email) can be sent and received.
- Multiple users can contribute to a single document using collaboration features.
- Remote-control programs can be used to troubleshoot problems or show new users how to perform a task.
- A single Internet connection can be shared among multiple computers.

Types of Networks

Several types of networks exist, from small, two-station arrangements to networks that interconnect offices in many cities:

- *Local area networks*. The smallest office network is referred to as a local area network (LAN). A LAN is formed from computers and components in a single office or building. A LAN can also be built at home from the same components used in office networking, but, as you'll see later, special home-networking components now exist to allow the creation of what can be called a home area network (HAN).
- *Home area networks*. A home area network (HAN) often uses the same hardware components as a LAN, but it is mainly used to share Internet access. Powerline, low-speed wireless, and phone-line networks are used primarily in HAN rather than LAN environments.
- *Wide area networks*. LANs in different locations can be connected together by high-speed fiber-optic, satellite, or leased phone lines to form a wide area network (WAN).
- *The Internet*. The World Wide Web is the most visible part of the world's largest network, the Internet. Although many users of the Internet still use modems over a dial-up connection rather than a LAN or WAN connection, any user of the Internet is a network user. The Internet is really a network of networks, all of which are connected to each other through the TCP/IP protocol. Programs such as Web browsers, File Transfer Protocol (FTP) clients, and newsreaders are some of the most common ways users work with the Internet.
- *Intranets*. Intranets use the same Web browsers and other software and the same TCP/IP protocol as the public Internet, but intranets exist as a portion of a company's private network. Typically, intranets comprise one or more LANs that are connected to other company networks, but, unlike the Internet, the content is restricted to authorized company users only. Essentially, an intranet is a private Internet.
- *Extranets*. Intranets that share a portion of their content with customers, suppliers, or other businesses, but not with the general public, are called extranets. As with intranets, the same Web browsers and other software are used to access the content.

Note

Both intranets and extranets rely on firewalls and other security tools and procedures to keep their private contents private. If you want to learn more about firewalls and security, I recommend picking up copies of

- *Absolute Beginner's Guide to Personal Firewalls*, ISBN: 0-7897-2625-4
- *Upgrading and Repairing Networks, Third Edition*, ISBN: 0-7897-2557-6

Requirements for a Network

Unless the computers that are connected know they are connected and agree on a common means of communication and what resources are to be shared, they can't work together. Networking software is just as important as networking hardware because it establishes the logical connections that make the physical connections work.

At a minimum, each network requires the following:

- Physical (cable) or wireless (infrared [IRDA] or radio-frequency) connections between computers
- A common set of communications rules, known as a *network protocol*
- Software that enables resources to be shared with other PCs and controls access to shared resources, known as a *network operating system*
- Resources that can be shared, such as printers, disk drives, and CD-ROMs
- Software that enables computers to access other computers with shared resources, known as a *network client*

These rules apply to the simplest and most powerful networks, and all the ones in between, regardless of their nature. The details of the hardware and software you need are discussed more fully later in this chapter.

Client/Server Versus Peer Networks

Although every computer on a LAN is connected to every other computer, they do not necessarily all communicate with each other. There are two basic types of LANs, based on the communication patterns between the machines—client/server networks and peer-to-peer networks.

Client/Server Networks

On a *client/server* network, every computer has a distinct role, that of either a client or a server. A *server* is designed to share its resources among the client computers on the network. Typically, servers are located in secured areas, such as locked closets or data centers, because they hold the organization's most valuable data and do not have to be accessed by operators on a continuous basis. The rest of the computers on the network function as *clients* (see Figure 20.1).

Servers

A dedicated server computer typically has a faster processor, more memory, and more storage space than a client because it might have to service dozens or even hundreds of users at the same time. High-performance servers also might use two or more processors, use the 64-bit version of the PCI expansion slot for server-optimized network interface cards, and have redundant power supplies. The server runs a special network operating system—such as Windows NT Server, Windows 2000 Server or Advanced Server, .NET Server, or Novell NetWare—that is designed solely to facilitate the sharing of its resources. These resources can reside on a single server or on a group of servers. When more than one server is used, each server can "specialize" in a particular task (file server, print server, fax server, email server, and so on) or provide redundancy (duplicate servers) in case of server failure. For very demanding computing tasks, several servers can act as a single unit through the use of parallel processing.

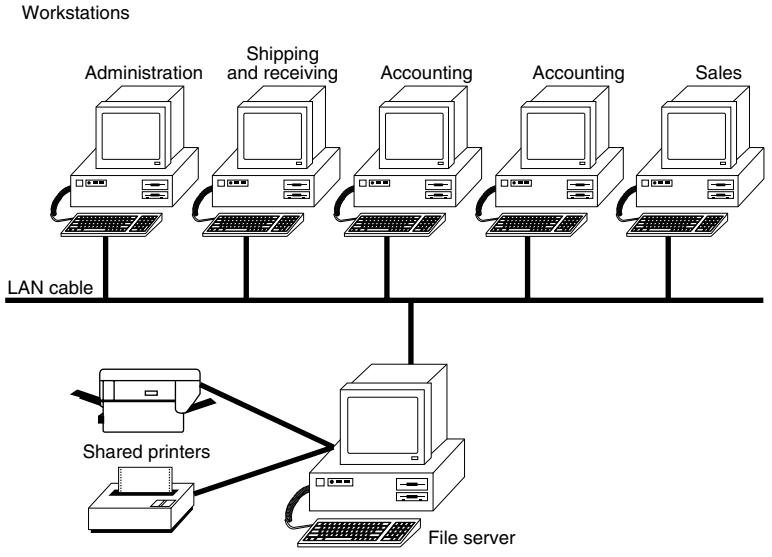


Figure 20.1 The components of a client/server LAN.

Clients

A client computer communicates only with servers, not with other clients. A client system is a standard PC that is running an operating system such as Windows 9x, Windows Me, Windows 2000 Professional, or Windows XP Professional. These versions of Windows contain the client software that enables the client computers to access the resources that servers share. Older operating systems, such as Windows 3.x and DOS, require add-on network client software.

Peer-to-Peer Network

By contrast, on a peer-to-peer network, every computer is equal and can communicate with any other computer on the network to which it has been granted access rights (see Figure 20.2). Essentially, every computer on a peer-to-peer network can function as both a server and a client; any computer on a peer-to-peer network is considered a server if it shares a printer, a folder, a drive, or some other resource with the rest of the network. This is why you might hear about client and server activities, even when the discussion is about a peer-to-peer network. Peer-to-peer networks can be as small as two computers or as large as hundreds of systems. Although there is no theoretical limit to the size of a peer-to-peer network, performance drops significantly and security becomes a major headache on peer-based networks with more than 10 computers. Also, Microsoft imposes a 10-station limit on computers running Windows 2000 Professional or XP Professional that are sharing resources with other systems. For these reasons, I recommend that you switch to a client/server network when your network climbs above about 10 stations.

Peer-to-peer networks are more common in small offices or within a single department of a larger organization. The advantage of a peer-to-peer network is that you don't have to dedicate a computer to function as a file server. Instead, every computer can share its resources with any other. The potential disadvantages to a peer-to-peer network are that typically less security and less control exist because users normally administer their own systems, whereas client/server networks have the advantage of centralized administration.

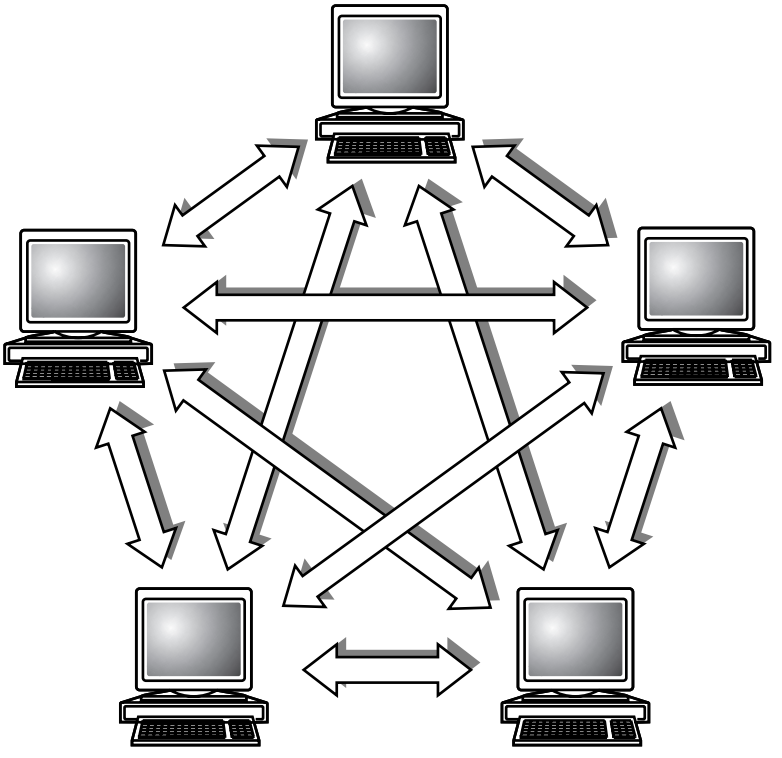

Figure 20.2 The logical architecture of a typical peer-to-peer network.

Comparing Client/Server and Peer-to-Peer Networks

Client/server LANs offer enhanced security for shared resources, greater performance, increased backup efficiency for network-based data, and the potential for the use of redundant power supplies and RAID drive arrays. Client/server LANs also have a much greater cost to purchase and maintain. Table 20.1 compares client/server and peer-to-peer server networking.

Table 20.1 Comparing Client/Server and Peer-to-Peer Networking

Item	Client/Server	Peer-to-Peer
Access control	Via user/group lists of permissions; single password provides a user access to only the resources on his list; users can be given several different levels of access.	Via password lists by resource; each resource requires a separate password; all-or-nothing access; no centralized user list.
Security	High because access is controlled by user or by group identity.	Low because knowing the password gives anybody access to a shared resource.
Performance	High because the server doesn't waste time or resources handling workstation tasks.	Low because servers often act as workstations.

Table 20.1 Continued

Item	Client/Server	Peer-to-Peer
Hardware Cost	High, due to specialized design of server, high-performance nature of hardware, and redundancy features.	Low because any workstation can become a server by sharing resources.
Software Cost	License fees per workstation user are part of the cost of the Network Operating System server software (Windows NT and Windows 2000 Server, .NET Server, and Novell NetWare).	It's free; all client software is included with any release of Windows 9x, Windows NT Workstation, Windows 2000 Professional, Windows Me, and WindowsXP.
Backup	Centralized when data is stored on server; enables use of high-speed, high-capacity tape back-ups with advanced cataloging.	Left to user decision; usually mixture of backup devices and practices at each workstation.
Redundancy	Duplicate power supplies, hot-swappable drive arrays, and even redundant servers are common; network OS normally is capable of using redundant devices automatically.	No true redundancy among either peer "servers" or clients; failures require manual intervention to correct, with a high possibility of data loss.

Windows 9x, Windows Me, Windows NT, Windows 2000, and Windows XP have peer-to-peer networking capabilities built into them. Because Windows, from version 95 forward, uses Plug and Play technology, installing network interface cards in a collection of these systems is relatively easy. Simply connect them with the correct kind of cable, and build your own peer-to-peer network.

Network Protocols: Ethernet Versus Token-Ring

The protocol you choose to run is the single most important decision you make when setting up a local area network. This protocol defines the speed of the network, the medium access control mechanism it uses, the types of cables you can use, the network interface adapters you must buy, and the adapter drivers you install in the network client software.

The Institute of Electrical and Electronic Engineers (IEEE) has defined and documented a set of standards for the physical characteristics of both collision-detection and token-passing networks. These standards are known as IEEE 802.3 (Ethernet) and IEEE 802.5 (Token-Ring). IEEE 802.11b defines a wireless version of Ethernet.

Note

Be aware, however, that the colloquial names Ethernet and Token-Ring actually refer to earlier versions of these protocols, on which the IEEE standards were based. Minor differences exist between the frame definitions for true Ethernet and true IEEE 802.3. In terms of the standards, IBM's 16Mbps Token-Ring products are an extension of the IEEE 802.5 standard. There is also an older data-link protocol called ARCnet that is now rarely used.

The two major choices today for wired networks are Ethernet and Token-Ring, but the other major network data-link protocols you might also encounter are summarized in Table 20.2. The abbreviations used for the cable types are explained in the following sections.

Table 20.2 Wired LAN Protocol Summary

Network Type	Speed	Maximum Number of Stations	Cable Types	Notes
ARCnet	2.5Mbps	255 stations	RG-62 coax UTP/ Type 1 STP	Obsolete for new installations; was used to replace IBM 3270 terminals (which used the same coax cable).
Ethernet	10Mbps	Per segment: 10BASE-T-2 10BASE-2-30 10BASE-5-100 10BASE-FL-2	UTP Cat 3 (10BASE-T), Thicknet (coax; 10BASE-5), Thinnet (RG-58 coax; 10BASE-2), fiber-optic (10BASE-F)	Largely replaced by Fast Ethernet; can be interconnected with Fast Ethernet by use of dual-speed hubs and switches; use switches and routers to overcome "5-4-3" rule in building very large networks.
Fast Ethernet	100Mbps	Per segment: 2	Cat 5 UTP	Fast Ethernet can be interconnected with standard Ethernet through the use of dual-speed hubs, switches, and routers. The most common variety is 100BASE-TX; alternative 100BASE-T4 is not widely supported.
Gigabit Ethernet	1,000Mbps	Per segment: 2	Cat 5 UTP	Gigabit Ethernet can be interconnected with Fast or standard Ethernet through the use of multispeed hubs, switches, and routers.
Token-Ring	4Mbps or 16Mbps	72 on UTP, 250-260 on type 1 STP	UTP, Type 1 STP, and Fiber Optic	High price for NICs and MSAUs to interconnect clients; primarily used with IBM midsize and mainframe systems.

▶▶ Wireless protocols, such as Wireless Ethernet IEEE 802.11b and others, are discussed later in this chapter. See "Wireless Network Standards," p. 1132.

A few years ago, the choice between Token-Ring or Ethernet wasn't easy. The original versions of standard Ethernet (10BASE-5 "Thick Ethernet" and 10BASE-2 "Thin Ethernet") used hard-to-install coaxial cable and were expensive to build beyond a certain point because of the technical limitations expressed by the "5-4-3" rule (see the following note).

Note

Ethernet signals can travel through no more than five segments, four repeaters or hubs, and three populated segments (cable segments with two or more stations) before they become unreliable. Because 10BASE-T hubs act as repeaters and a 10BASE-T segment has only one station per cable, creating large networks is easier with 10BASE-T Ethernet than with older forms of Ethernet.

Initially, Token-Ring's 16Mbps version was substantially faster than 10BASE versions of Ethernet and had larger limits on the numbers of workstations permitted per segment. Currently, however, the popularity and low cost of Fast Ethernet; the use of easy-to-install twisted-pair cabling for standard, 100Mbps Fast, and even 1000Mbps Gigabit Ethernet; and the use of hubs and switches to overcome classic Ethernet station limitations have made Fast Ethernet the preferred choice for workgroup-size networks and a competitor to Token-Ring for larger networks. A properly designed Fast Ethernet network can be upgraded to Gigabit Ethernet in the future.

Ethernet

With tens of millions of computers connected by Ethernet cards and cables, Ethernet is the most widely used data link layer protocol in the world. Ethernet-based LANs enable you to interconnect a wide variety of equipment, including Unix and Linux workstations, Apple computers, printers, and PCs. You can buy Ethernet adapters from dozens of competing manufacturers, supporting all three of the cable types defined in the standard: Thinnet, Thicknet, and Unshielded Twisted Pair (UTP). Traditional Ethernet operates at a speed of 10Mbps, but the more recent (and most popular of the Ethernet flavors) Fast Ethernet standards push this speed to 100Mbps. The latest version of Ethernet, Gigabit Ethernet, reaches speeds of 1,000Mbps, or 100 times the speed of original Ethernet.

Fast Ethernet

Fast Ethernet requires adapters, hubs, and UTP or fiber-optic cables designed to support the higher speed, but you can buy combination devices that run at both 10Mbps and 100Mbps, enabling you to gradually upgrade your network by installing new NICs and hubs over an extended period of time.

Both the most popular form of Fast Ethernet (100BASE-TX) and 10BASE-T standard Ethernet use two of the four wire pairs found in UTP Category 5 cable. An alternative Fast Ethernet standard called 100BASE-T4 uses all four wire pairs in UTP Category 5 cable, but this Fast Ethernet standard was never popular and is seldom seen today.

Gigabit Ethernet

Gigabit Ethernet also requires special adapters, hubs, and cables. Most users of Gigabit Ethernet use fiber-optic cables, but you can run Gigabit Ethernet over the same Category 5 UTP cabling that Fast Ethernet and newer installations of standard Ethernet use. Gigabit Ethernet for UTP is also referred to as 1000BASE-T.

Unlike Fast Ethernet and standard Ethernet over UTP, Gigabit Ethernet uses all four wire pairs. Thus, Gigabit Ethernet requires dedicated Ethernet cabling; you can't "borrow" two wire pairs for telephone or other data signaling with Gigabit Ethernet as you can with the slower versions. Most Gigabit Ethernet adapters can also handle 10BASE-T and 100BASE-TX Fast Ethernet traffic, enabling you to interconnect all three UTP-based forms of Ethernet on a single network.

Neither Fast Ethernet nor Gigabit Ethernet support the use of thin or thick coaxial cable originally used with traditional Ethernet, although you can interconnect coaxial-cable-based and UTP-based Ethernet networks by using media converters or specially designed hubs and switches.

Note

For more information about Ethernet, Fast Ethernet, Token-Ring, and other network data-link standards, see the "Data Link Layer Protocols" and "High-Speed Networking Technologies" sections found in Chapter 19 of *Upgrading and Repairing PCs, 11th Edition*, available in electronic form on the DVD provided with this book.

Hardware Elements of Your Network

The choice of a data-link protocol affects the network hardware you choose. Because Ethernet, Fast Ethernet, Token-Ring, and other data-link protocols use different hardware, you must select the protocol before you can select appropriate hardware, including network interface cards, cables, and hubs or switches.

Network Interface Cards

On most computers, the network interface adapter takes the form of a network interface card (NIC) that fits into a PCI slot on a desktop computer or a PC Card (PCMCIA) slot on a notebook computer. Although network cards for older systems might use the ISA or EISA slot standards, these don't support high-speed network standards and are obsolete. Some systems incorporate the network interface adapter onto the motherboard, but this practice is more commonly found in workstations and portable computers and rarely in servers because most network administrators prefer to select their own NICs.

Ethernet and Token-Ring adapters have unique hardware addresses coded into their firmware. The data link layer protocol uses these addresses to identify the other systems on the network. A packet gets to the correct destination because its data link layer protocol header contains the hardware addresses of both the sending and receiving systems.

10/100 Ethernet network adapters range in price from under $20 for client adapters to as much as $300 or more for server-optimized adapters. Token-Ring adapters are much more expensive, ranging in price from around $170 for client adapters to more than $500 for server-optimized adapters. Network adapters are built in all the popular interface-card types and are also optimized for either workstation or server use. For first-time network users, so-called network-in-a-box kits are available that contain two 10/100 Fast Ethernet NICs, a small hub or switch, and prebuilt UTP cables for around $100. When combined with the built-in networking software in Windows, these kits make networking very inexpensive. A number of 10/100/1000-BASETX Gigabit Ethernet adapters for use with UTP cable can be purchased for under $60, and some 10/100 switches now also feature Gigabit Ethernet ports.

For client workstations (including peer servers on peer-to-peer networks), the following sections contain my recommendations on the features you need.

Speed

Your NIC should run at the maximum speed you want your network to support. For a Fast Ethernet network, for example, you should purchase Ethernet cards that support 100BASE-TX's 100Mbps speed. Most Fast Ethernet cards also support standard Ethernet's 10Mbps speed, allowing the same card to be used on both older and newer portions of the network. To verify dual-speed operation, look for network cards identified as 10/100 Ethernet.

Your NIC should support both half-duplex and full-duplex operation:

- *Half-duplex* means that the network card can only send or only receive data in a single operation.
- *Full-duplex* means that the network card can both receive and send simultaneously. Full-duplex options boost network speed if switches are used in place of hubs.

Unlike hubs, which broadcast data packets to all computers connected to it, switches create a direct connection between the sending and receiving computers. Thus, switches provide faster performance

than hubs; most switches also support full-duplex operation, doubling the rated speed of the network when full-duplex network cards are used.

Although, at one time, switches were hard to justify on a workgroup peer-to-peer LAN because of their extra cost, switches are now available for little more than the price of hubs with a similar number of ports and are recommended for LANs of any size. If you plan to use your Ethernet-based home or office network to share an Internet connection, consider purchasing a router with an integrated switch. This combination makes networking simple and requires less space than separate routers and switches. Many router/switch combinations cost little more than a switch or router would separately. For other types of networks, you can use a gateway to connect your network with the Internet.

Bus Type

If you are networking desktop computers built from 1995 to the present, you should consider only PCI-based NICs (these computers typically have three or more PCI slots). Although many computers still have at least one ISA or combo ISA/PCI expansion slot, the superior data bus width and data transfer rate of PCI make it the only logical choice for networks of all types. The integrated NIC found on some recent PC motherboards is also a PCI device.

Table 20.3 summarizes the differences between these expansion slot types.

Table 20.3 Bus Choices for Client PC NICs

Slot Type	Speed	Bus Width
PCI	33MHz[1]	32-bit[2]
ISA	8.33MHz[3]	16-bit[4]

1. A PCI speed of 33MHz assumes a motherboard (frontside bus) speed of 66MHz, 100MHz, or 133MHz; other motherboard speeds could cause this to vary. Some servers have PCI slots that can also run at 66MHz.

2. Some PCI host adapters made for network servers are 64-bit or can operate in either 64-bit or 32-bit PCI slots.

3. An ISA speed of 8.33MHz assumes a default of PCI clock speed/4; variations in motherboard speed or PCI clock divisor could cause this to vary.

4. Some ISA slots are only 8-bit design.

Although a few ISA-based NICs are still on the market, their slow speeds and narrow bus widths severely restrict their performance. Most ISA-based Ethernet cards can't support speeds above 10Mbps and thus don't support Fast Ethernet or Gigabit Ethernet. A few vendors make 10/100 Ethernet cards for the ISA slot, but their performance is substantially lower than PCI cards.

Network Adapter Connectors

Ethernet adapters typically have a connector that looks like a large telephone jack called an RJ-45 (for 10BASE-T and Fast Ethernet twisted-pair cables), a single BNC connector (for Thinnet coaxial cables), or a D-shaped 15-pin connector called a DB15 (for Thicknet coaxial cables). A few older 10Mbps adapters have a combination of two or all three of these connector types; adapters with two or more connectors are referred to as *combo* adapters. Token-Ring adapters can have a 9-pin connector called a DB9 (for Type 1 STP cable) or sometimes an RJ-45 jack (for Type 3 UTP cable). Figure 20.3 shows all three of the Ethernet connectors.

The following figures provide profile views of the most common types of NIC connections. Figure 20.4 shows a 10BASE-2 NIC configured to be at the end of a network; the T-adapter connected to the BNC connector has a Thinnet (RG-58) cable attached to one side and a 50-ohm terminator at the other end.

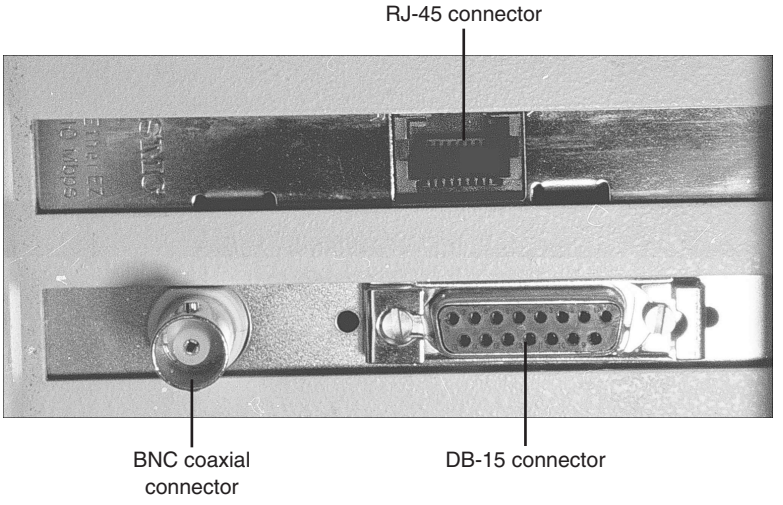

Figure 20.3 Three Ethernet connectors on two NICs: RJ-45 connector (left), DB-15 connector (top right), and BNC connector (bottom right).

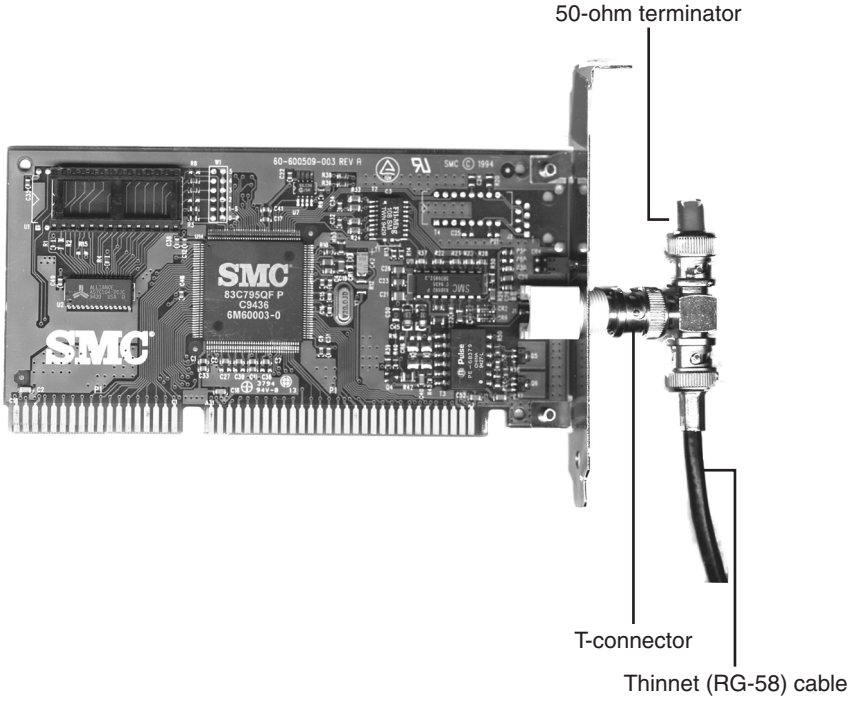

Figure 20.4 An Ethernet 10BASE-2 NIC configured as the last station in a Thin Ethernet network.

Figure 20.5 shows a 10BASE-T NIC with its UTP cable attached.

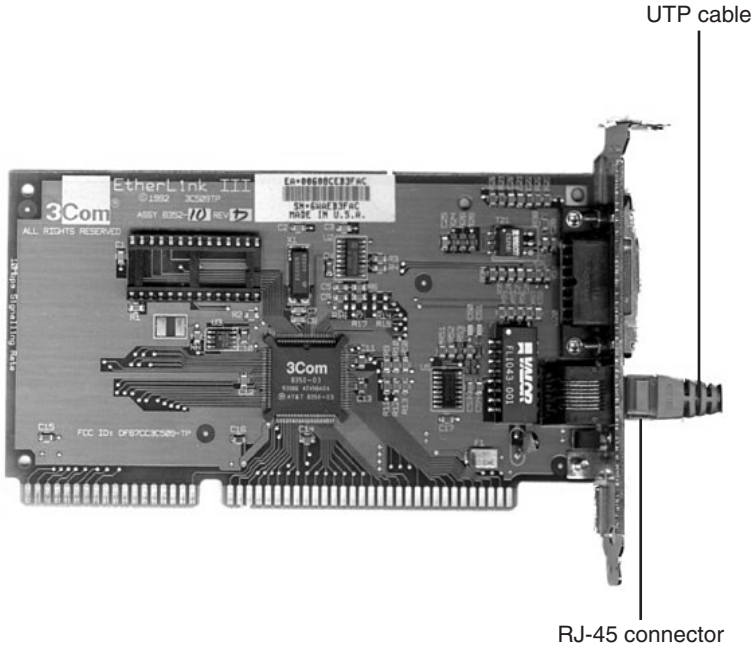

Figure 20.5 An Ethernet 10BASE-T NIC with a UTP cable attached.

Virtually all standard and 10/100 Ethernet NICs made for client-PC use on the market today are designed to support unshielded twisted-pair (UTP) cable exclusively; Gigabit Ethernet cards made for wired (not fiber-optic) networks also use only UTP cable. If you are adding a client PC to an existing network that uses some form of coaxial cable, you have three options:

- Purchase a combo NIC that supports coaxial cable as well as RJ-45 twisted-pair cabling.
- Purchase a media converter that can be attached to the coaxial cable to allow the newer UTP-based NICs to connect to the existing network.
- Use a switch or hub that has both coaxial cable and RJ-45 ports. A dual-speed (10/100) device is needed if you are adding one or more Fast Ethernet clients.

For maximum economy, NICs and network cables must match, although media converters can be used to interconnect networks based on the same standard, but using different cable.

Network Cables

Originally, all networks used some type of cable to connect the computers on the network to each other. Although various types of wireless networks are now on the market, most office and home networks are still based on one of the following wired topologies:

- Coaxial cable
- Twisted-pair cabling

Thick and Thin Ethernet Coaxial Cable

The first versions of Ethernet were based on coaxial cable. The original form of Ethernet, 10BASE-5, used a thick coaxial cable (called Thicknet) that was not directly attached to the NIC. A device called an attachment unit interface (AUI) ran from a DB15 connector on the rear of the NIC to the cable. The cable had a hole drilled into it to allow the "vampire tap" to be connected to the cable. NICs designed for use with thick Ethernet cable are almost impossible to find as new hardware today.

10BASE-2 Ethernet cards use a BNC (Bayonet-Neill-Concilman) connector on the rear of the NIC. Although the thin coaxial cable (called Thinnet or RG-58) used with 10BASE-2 Ethernet has a bayonet connector that can physically attach to the BNC connector on the card, this configuration is incorrect and won't work. Instead, a BNC T-connector attaches to the rear of the card, allowing a thin Ethernet cable to be connected to either both ends of the T (for a computer in the middle of the network) or to one end only (for a computer at the end of the network). A 50-ohm terminator is connected to the other arm of the T to indicate the end of the network and prevent erroneous signals from being sent to other clients on the network. Some early Ethernet cards were designed to handle thick (AUI/DB15), thin (RG-58), and UTP (RJ-45) cables. Combo cards with both BNC and RJ-45 connectors are still available but can run at only standard Ethernet speeds.

Figure 20.6 compares Ethernet DB-15 to AUI, BNC coaxial T-connector, and RJ-45 UTP connectors to each other, and Figure 20.7 illustrates the design of coaxial cable.

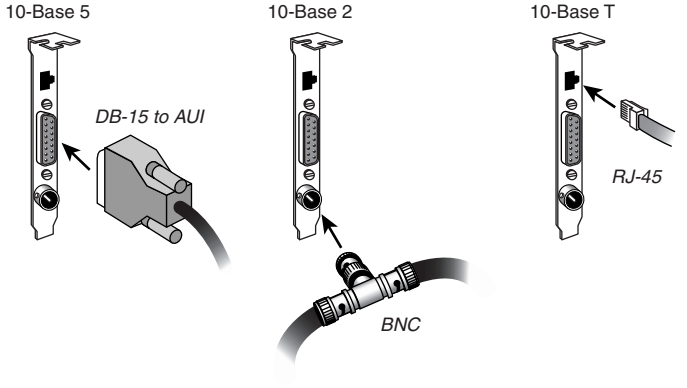

Figure 20.6 An Ethernet network card with thick Ethernet (DB-15), thin Ethernet (RG-58 with T-connector), and UTP (RJ-45) connectors.

Twisted-Pair Cable

Twisted-pair cable is just what its name implies: insulated wires within a protective casing with a specified number of twists per foot. Twisting the wires reduces the effect of electromagnetic interference (that can be generated by nearby cables, electric motors, and fluorescent lighting) on the signals being transmitted. Shielded twisted pair (STP) refers to the amount of insulation around the cluster of wires and therefore its immunity to noise. You are probably familiar with unshielded twisted-pair (UTP) cable; it is often used for telephone wiring. Figure 20.8 shows unshielded twisted-pair cable; Figure 20.9 illustrates shielded twisted-pair cable.

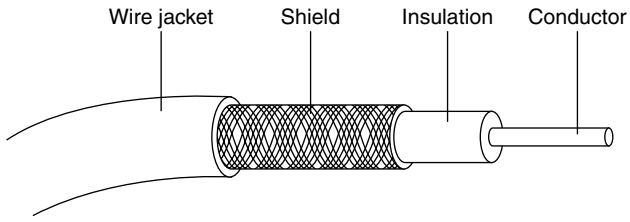

Figure 20.7 Coaxial cable.

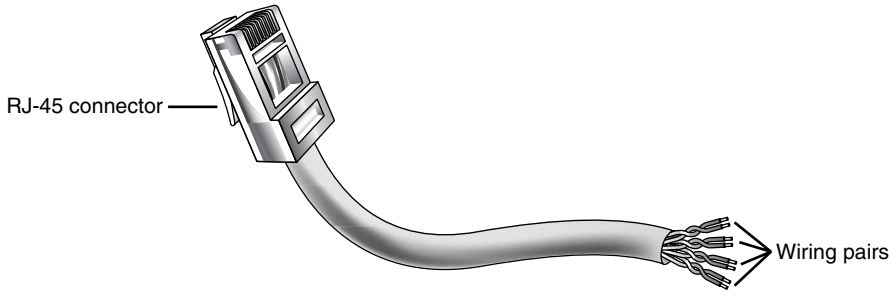

Figure 20.8 An unshielded twisted-pair (UTP) cable.

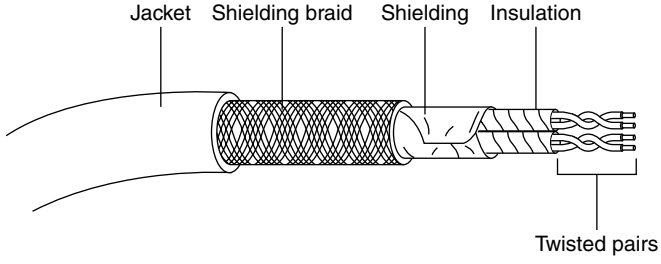

Figure 20.9 A shielded twisted-pair (STP) cable.

Shielded Versus Unshielded Twisted Pair

When cabling was being developed for use with computers, it was first thought that shielding the cable from external interference was the best way to reduce interference and provide for greater transmission speeds. However, it was discovered that twisting the pairs of wires is a more effective way to prevent interference from disrupting transmissions. As a result, earlier cabling scenarios relied on shielded cables rather than the unshielded cables more commonly in use today.

Shielded cables also have some special grounding concerns because one, and only one, end of a shielded cable should be connected to an earth ground; issues arose when people inadvertently caused grounding loops to occur by connecting both ends or caused the shield to act as an antenna because it wasn't grounded.

Grounding loops are situations in which two different grounds are tied together. This is a bad situation because each ground can have a slightly different potential, resulting in a circuit that has very low voltage but infinite amperage. This causes undue stress on electrical components and can be a fire hazard.

Most Ethernet and Fast Ethernet installations that use twisted-pair cabling use UTP because the physical flexibility and small size of the cable and connectors makes routing it very easy. However, its lack of electrical insulation can make interference from fluorescent lighting, elevators, and alarm systems (among other devices) a major problem. If you use UTP in installations where interference can be a problem, you need to route the cable away from the interference, use an external shield, or substitute STP for UTP near interference sources.

Network Topologies

Each computer on the network is connected to the other computers with cable (or some other medium). The physical arrangement of the cables connecting computers on a network is called the network *topology*.

The three types of topologies used in computer networks are as follows:

- *Bus*. Connects each computer on a network directly to the next computer in a linear fashion. The network connection starts at the server and ends at the last computer in the network.
- *Star*. Connects each computer on the network to a central access point.
- *Ring*. Connects each computer to the others in a loop or ring.

These different topologies are often mixed, forming what is called a *hybrid network*. For example, you can link the hubs of several star networks together with a bus, forming a star-bus network. Rings can be connected in the same way.

Table 20.4 summarizes the relationships between network types and topologies.

Table 20.4 Network Cable Types and Topologies

Network Type	Standard	Cable Type	Topology
Ethernet	10BASE-2	Thick coaxial	Bus
	10BASE-5	Thin (RG-58) coaxial	Bus
	10BASE-T	Cat 3 or Cat 5 UTP	Star
Fast Ethernet	100BASE-TX	Cat 5 UTP	Star
Gigabit Ethernet	1000BASE-TX	Cat 5 UTP	Star
Token-Ring	(all)	STP or coaxial	Logical Ring

The bus, star, and ring topologies are discussed in the following sections.

Bus Topology

The earliest type of network topology was the *bus topology*, which uses a single cable to connect all the computers in the network to each other, as shown in Figure 20.10. This network topology was adopted initially because running a single cable past all the computers in the network is easier and less wiring is used than with other topologies. Because early bus topology networks used bulky coaxial cables, these factors were important advantages. Both 10BASE-5 (thick) and 10BASE-2 (thin) Ethernet networks are based on the bus topology.

However, the advent of cheaper and more compact unshielded twisted-pair cabling, which also supports faster networks, has made the disadvantages of a bus topology apparent. If one computer or cable connection malfunctions, it can cause all the stations beyond it on the bus to lose their network connections. Thick Ethernet (10BASE-5) networks often fail because the vampire tap connecting the

AUI device to the coaxial cable comes loose. In addition, the T-adapters and terminating resistors on a 10BASE-2 Thin Ethernet network can also come loose or be removed by the user, causing all or part of the network to fail. Another drawback of Thin Ethernet (10BASE-2) networks is that adding a new computer to the network between existing computers might require replacement of the existing network cable between the computers with shorter segments to connect to the new computer's network card and T-adapter.

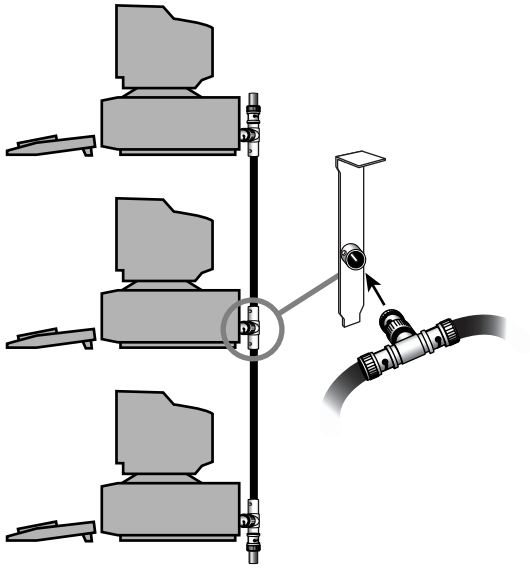

Figure 20.10 A 10BASE-2 network is an example of a linear bus topology, attaching all network devices to a common cable.

Ring Topology

Another topology often listed in discussions of this type is a *ring*, in which each workstation is connected to the next and the last workstation is connected to the first again (essentially a bus topology with the two ends connected). Two major network types use the ring topology:

- *Fiber Distributed Data Interface (FDDI)*. A network topology used for large, high-speed networks using fiber-optic cables in a physical ring topology
- *Token-Ring*. Uses a logical ring topology

A Token-Ring network resembles a 10BASE-T or 10/100 Ethernet network at first glance because both networks use a central connecting device and a physical star topology. Where is the "Ring" in Token-Ring?

The ring exists only within the device that connects the computers, which is called a *multistation access unit (MSAU)* on a Token-Ring network (see Figure 20.11).

Signals generated from one computer travel to the MSAU, are sent out to the next computer, and then go back to the MSAU again. The data is then passed to each system in turn until it arrives back at the computer that originated it, where it is removed from the network. Therefore, although the physical wiring topology is a star, the data path is theoretically a ring. This is called a *logical ring*.

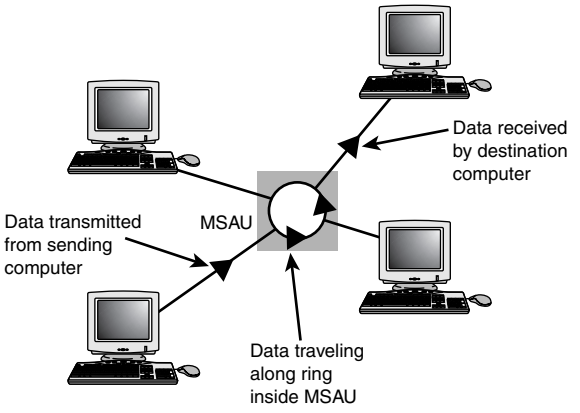

Figure 20.11 A Token-Ring network during the sending of data from one computer to another.

A logical ring that Token-Ring networks use is preferable to a physical ring network topology because it affords a greater degree of fault tolerance. As on a bus network, a cable break anywhere in a physical ring network topology, such as FDDI, affects the entire network. FDDI networks use two physical rings to provide a backup in case one ring fails. By contrast, on a Token-Ring network, the MSAU can effectively remove a malfunctioning computer from the logical ring, enabling the rest of the network to function normally.

Star Topology

The most popular type of topology in use today has separate cables to connect each computer to a central wiring nexus, often called a *hub* or *concentrator*; a switch can also be used in place of a hub. Figure 20.12 shows this arrangement, which is called a *star topology*.

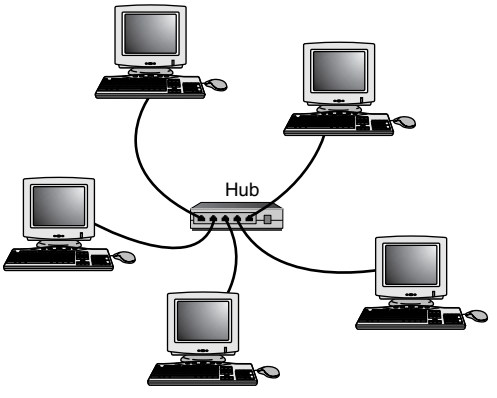

Figure 20.12 The star topology, linking the LAN's computers and devices to one or more central hubs, or access units.

Because each computer uses a separate cable, the failure of a network connection affects only the single machine involved. The other computers can continue to function normally. Bus cabling schemes use less cable than the star but are harder to diagnose or bypass when problems occur. At this time,

Fast Ethernet in a star topology is the most commonly implemented type of LAN; this is the type of network you build with most preconfigured network kits. 10BASE-T Ethernet and 1000BASE-TX Gigabit Ethernet also use the star topology. 10BASE-T can use either Category 3 or Category 5 UTP, whereas Fast Ethernet and Gigabit Ethernet require Category 5 UTP.

Hubs and Switches for Ethernet Networks

As you have seen, modern Ethernet workgroup networks are based on UTP cable with workstations arranged in a star topology. The center of the star uses a multiport connecting device that can be either a hub or a switch. Although hubs and switches can be used to connect the network—and can have several features in common—the differences between them are also significant and are covered in the following sections.

All Ethernet hubs and switches have the following features:

- Multiple RJ-45 UTP connectors
- Diagnostic and activity lights
- A power supply

Ethernet hubs and switches are made in two forms: managed and unmanaged. *Managed* hubs and switches can be configured, enabled or disabled, or monitored by a network operator and are commonly used on corporate networks. Workgroup and home-office networks use less expensive *unmanaged* hubs, which simply connect computers on the network.

Note

The now-obsolete ARCnet network used its own types of hubs: passive hubs, which were unpowered, and active hubs, which used a power supply. Neither type of hub is compatible with Ethernet.

The connection between each workstation and the hub or switch is the UTP cable running from the RJ-45 jack on the rear of the NIC to the RJ-45 jack on the rear of the hub or switch.

Signal lights on the front of the hub or switch indicate which connections are in use by computers; switches also indicate whether a full-duplex connection is in use. Multispeed hubs and switches also indicate which connection speed is in use on each port. Your hub or switch must have at least one RJ-45 UTP connector for each computer you want to connect to it. Figure 20.13 shows a typical five-port, 10/100 Ethernet hub suitable for small networks at home or in a small business.

Figure 20.13 A typical 10/100, five-port workgroup hub. *Photo courtesy of Linksys*.

How Hubs Work

A computer on an Ethernet network broadcasts (sends) a request for network information or programs from a specific computer through the cable to the hub, which broadcasts the request to all computers connected to it. When the destination computer receives the message, it sends the requested information back to the hub, which broadcasts it again to all computers, although only the requesting computer acts on the information. Thus, a hub acts similarly to a radio transmitter and receiver that sends a signal to all radios, but only the radios set for the correct station can send or receive the information.

How Switches Differ from Hubs

Switches are similar to hubs in that they connect computers on a UTP-based Ethernet network to each other and physically resemble hubs (see Figure 20.14). However, instead of broadcasting data to all computers on the network as hubs do, switches use a feature called *address storing*, which checks the destination for each data packet and sends it directly to the computer it's intended for. Thus, a switch can be compared to a telephone exchange, making direct connections between the originator of a call and the receiver.

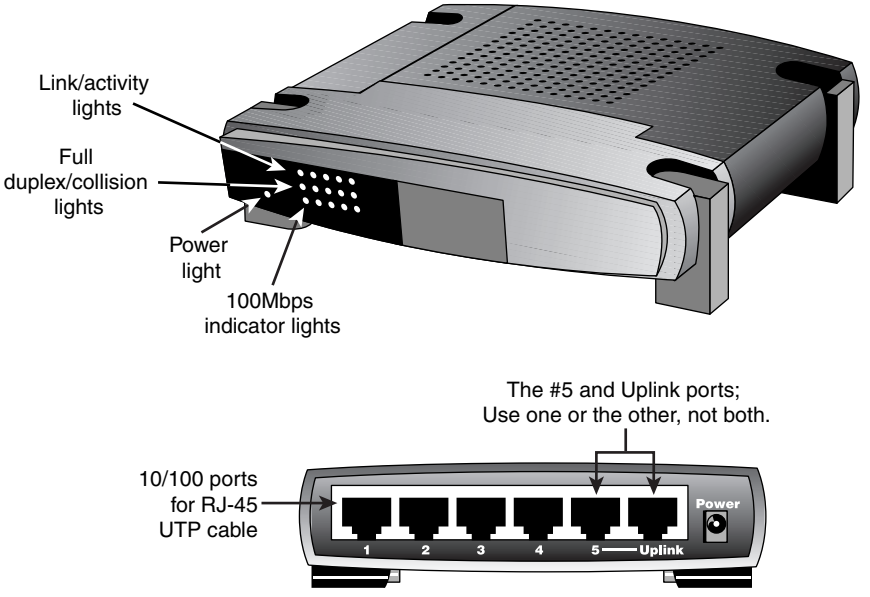

Figure 20.14 Front (top) and rear (bottom) of a typical five-port, 10/100 Ethernet switch.

Because switches establish a direct connection between the originating and receiving PC, they also provide the full bandwidth of the network to each port. Hubs, by contrast, must subdivide the network's bandwidth by the number of active connections on the network, meaning that bandwidth rises and falls depending on network activity.

For example, assume you have a four-station network workgroup using 10/100 NICs and a Fast Ethernet hub. The total bandwidth of the network is 100Mbps. However, if two stations are active, the effective bandwidth available to each station drops to 50Mbps (100Mbps divided by 2). If all four

stations are active, the effective bandwidth drops to just 25Mbps (100Mbps divided by 4)! Add more active users, and the effective bandwidth continues to drop.

By replacing the hub with a switch, the effective bandwidth for each station remains 100Mbps because the switch doesn't broadcast data to all stations.

Most 10/100 NICs and Fast Ethernet or 10/100 switches also support full-duplex (simultaneous transmit and receive), enabling actual bandwidth to be double the nominal 100Mbps rating: 200Mbps. Table 20.5 summarizes the differences between the two devices.

Table 20.5 Ethernet Hub and Switch Comparison

Feature	Hub	Switch
Bandwidth	Divided by total number of ports in use	Dedicated to each port in use
Data Transmission Type	Broadcast to all connected computers	Direct connection between transmitting and receiving computers
Duplex Support	Half-duplex only (receive or transmit)	Half- or full-duplex (receive and transmit) when used with full-duplex NICs; doubles effective bandwidth of the network

As you can see, using a switch instead of a hub greatly increases the effective speed of a network, even if all other components remain the same.

Because of the improved performance of switches, I recommend them instead of hubs for networks of any size.

Additional Hub and Switch Features You Might Need

The least-expensive hubs and switches are those that run at only a single speed and have only a few RJ-45 connectors. Depending on your needs, you might find the following options useful:

- *Dual-speed hubs/switches*. If you are adding Fast Ethernet (100BASE-TX) clients to an existing 10BASE-T network, you need a dual-speed hub or switch to connect the various types of Ethernet together.

  Even if you are building a brand-new Fast Ethernet network, a dual-speed hub or switch is useful for occasionally hosting a "guest" PC that has only a standard 10BASE-T Ethernet NIC onboard. Even though most Fast Ethernet switches and hubs on the market today are actually 10/100 dual-speed models, you might still encounter a Fast Ethernet-only unit. These should be used only on networks that will never have a 10BASE-T connection.

- *Stackable hub or switch with an uplink port*. A *stackable* hub or switch is one that can be connected to another hub, enabling you to add computers to your network without replacing the hub or switch every time it runs out of connections. Most hubs and switches on the market today are stackable (but very small) hubs, and some older models might lack this feature. You can use this feature to add 10/100 features to an older 10BASE-T-only network and connect a dual-speed hub or switch to the uplink port on your 10BASE-T hub.

- *"Extra" ports beyond your current requirements.* If you are connecting four computers together into a small network, you need a four-port hub or switch (the smallest available). But, if you buy a hub or switch with only four ports and want to add another client PC to the network, you must add a second hub or switch or replace the hub or switch with a larger one with more ports.

  Instead, plan for the future by buying a hub or switch that can handle your projected network growth over the next year. If you plan to add two workstations, buy at least a six-port hub or switch (the cost per connection drops as you buy hubs with more connections). Even though most hubs and switches are stackable to support the growth of your network, the more ports a hub or switch has, the less expensive per port it will be.

To determine whether a hub or switch is stackable, look for an uplink port. This port looks like an ordinary RJ-45 UTP port, but it is wired differently, enabling you to use a standard-pinout RJ-45 UTP cable to connect it to another hub. Without the uplink port, you'd have to use a specially wired crossover cable.

Typically, hubs and switches with an uplink port allow you to use the port along with all but one of the normal ports on the hub (see Figure 20.15). For example, one of my associates uses a five-port switch from Linksys that also contains a router (for Internet access) and an uplink port. If his office network expands beyond five computers, he can use the uplink port to add another switch to expand the network and provide the new stations, as well as the original network, with Internet access.

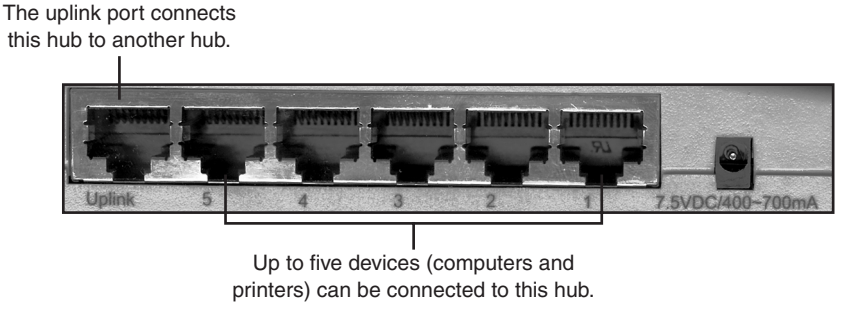

Figure 20.15 The connectors on a typical five-port workgroup hub with an uplink port (at left) for connecting this hub to another hub (stacking the hubs). Either port #5 or the uplink port can be used, but not both.

Hub and Switch Placement

Although large networks have a wiring closet near the server, the workgroup-size LANs you'll be building don't need a wiring closet. However, the location of the hub or switch is important.

Ethernet hubs and switches require electrical power, whether they are small units that use a power "brick" or larger units that have an internal power supply and a standard three-prong AC cord.

In addition to electrical power, consider placing the hub or switch where its signal lights will be easy to view for diagnostic purposes and where its RJ-45 connectors can be reached easily when it's time to add another user or two. In many offices, the hub or switch sits on the corner of the desk, enabling the user to see network problems just by looking at the hub or switch.

If the hub or switch also integrates a router for use with a broadband Internet device, such as a DSL or cable modem, you can place it near the cable or DSL modem or at a distance if the layout of your

home or office requires it. Because the cable or DSL modem usually connects to your computer by the same Category 5 cable used for UTP Ethernet networking, you can run the cable from the cable or DSL modem to the router/switch's WAN port and connect all the computers to the LAN ports on the router/switch.

Except for the 328' (100 meter) limit for all forms of UTP Ethernet (10BASE-T, 100BASE-TX, and 1000BASE-TX), distances between each computer on the network and the hub or switch aren't critical, so put the hub or switch wherever you can supply power and gain easy access.

Tip

Decide where you plan to put your hub or switch before you buy prebuilt UTP wiring or make your own; if you move the hub or switch, some of your wiring will no longer be the correct length. Although excess lengths of UTP cable can be coiled and secured with cable ties, cables that are too short should be replaced. You can buy RJ-45 connectors to create one long cable from two short cables, but you must ensure they are Category 5 if you are running Fast Ethernet. You're really better off replacing the too-short cable with the correct length.

Network Cable Installations

If you have to run cables (of any type) through existing walls and ceilings, the cable installation can be the most expensive part of setting up a LAN. At every branching point, special fittings connect the intersecting wires. Sometimes, you also need various additional components along the way, such as hubs, repeaters, or MSAUs.

Note

As an alternative to wired networks, more and more companies and home users are exploring wireless networks using radio waves and other technologies. Although these networks are not yet as fast as wired solutions such as Fast Ethernet, they are useful for solutions in which wiring isn't feasible or when speed is not important. See the section "Wireless Network Standards," later in this chapter, for details.

With the development of easy-to-build (or prebuilt) Category 5 twisted-pair cabling, high-speed and low-cost NICs and hubs, and built-in basic networking in current versions of Windows, installing and setting up a network today is far easier than ever before. For small cubicle/office networking in which no wire must be routed through walls and in which Windows peer networking software will be used, you should be able to set up the network yourself.

If your wiring must go through walls, be run through dropped ceilings, be piggybacked on air ducts, or be run between floors, you might want to have professional network-cable specialists install the cable. A good company knows the following:

- When UTP (unshielded twisted-pair) cabling is adequate
- Where STP (shielded twisted-pair) cabling might be necessary to avoid excessive cable runs and interference
- How to route cable between rooms, floors, and nonadjacent offices
- How to use wall panels to make cable attachments look better and more professional
- When you must use fireproof Plenum cable
- How to deal with sources of electrical interference, such as elevator motors, transmitters, alarm systems, and even florescent office lighting, by using fiber-optic or shielded cable

If you decide you need professional cable installation, be sure to get a firm price quote first because the cost of a complex cable installation might make a wireless network a more appealing choice.

Selecting the Proper Cable

A network is only as fast as its slowest component; to achieve the maximum speeds of the network, all its components, including cables, must meet the standards. Two standard types of twisted pair cabling exist:

- *Category 3 cable.* The original type of UTP cable used for Ethernet networks was also the same as that used for business telephone wiring. This is known as Category 3, or voice-grade UTP cable, and is measured according to a scale that quantifies the cable's data-transmission capabilities. The cable itself is 24 AWG (American Wire Gauge, a standard for measuring the diameter of a wire), copper-tinned with solid conductors, 100–105 ohm characteristic impedance, and a minimum of two twists per foot. Category 3 cable is adequate for networks running at up to 16Mbps. This cable usually looks like "silver" telephone cable, but with the larger RJ-45 connector. Category 3 cabling is obsolete because it doesn't support Fast Ethernet or greater network speeds.
- *Category 5 cable.* The newer, faster network types require greater performance levels. Fast Ethernet (100BASE-TX) uses the same two-wire pairs as 10BASE-T, but Fast Ethernet needs a greater resistance to signal crosstalk and attenuation. Therefore, the use of Category 5 UTP cabling is essential with 100BASE-TX Fast Ethernet. Although the 100BASE-T4 version of Fast Ethernet can use all four-wire pairs of Category 3 cable, this flavor of Fast Ethernet is not widely supported and has practically vanished from the marketplace. Thus, for practical purposes, if you mix Category 3 and Category 5 cables, you should use only 10BASE-T (10Mbps) Ethernet hubs; if you try to run Fast Ethernet 100BASE-TX over Category 3 cable, you will have a slow and unreliable network.

Many cable vendors also sell an enhanced form of Category 5 cable called Category 5e. Category 5e cable can be used in place of Category 5 cable and is especially well-suited for use in Fast Ethernet networks that might be upgraded to Gigabit Ethernet in the future. Category 5e cabling must pass several tests not required for Category 5 cabling. Even though you can use both Category 5 and Category 5e cabling on a Gigabit Ethernet network, Category 5e cabling provides better transmission rates.

You should use existing Category 3 cable for your LAN only if you are content with the 10Mbps speeds of 10BASE-T and if the cable is in good condition. The silver exterior on Category 3 cabling can become brittle and deteriorate, leading to frequent network failures. If you are installing brand-new wiring for a new network or replacing deteriorated Category 3 cable, Category 5 or Category 5e cabling should be used. Both types are widely available either in prebuilt assemblies or in bulk.

Caution

If you choose to install Category 5/5e UTP cable, be sure that all the connectors, wall plates, and other hardware components involved are also Category 5-rated.

If you are trying to connect prebuilt Category 5 cabling together on a Fast Ethernet network, use Category 5–grade connectors; otherwise, you'll create a substandard section that might fail in your network.

Choosing the correct type of Category 5/5e cable is also important. Use solid PVC cable for network cables that represent a permanent installation. However, the slightly more expensive stranded cables are a better choice for a notebook computer or temporary wiring of no more than 10' lengths (from a computer to a wall socket, for example) because it is more flexible and is therefore capable of withstanding frequent movement.

If you plan to use air ducts or suspended ceilings for cable runs, you should use Plenum cable, which doesn't emit harmful fumes in a fire. It is much more expensive, but the safety issue is a worthwhile reason to use it (and it is required by some localities).

Building Your Own Twisted-Pair Cables

When it's time to wire your network, you have two choices. You can opt to purchase prebuilt cables, or you can build your own cables from bulk wire and connectors.

You should build your own twisted-pair cables if you

- Plan to perform a lot of networking
- Need cable lengths longer than the lengths you can buy preassembled at typical computer departments
- Want to create both standard and crossover cables
- Want to choose your own cable color
- Want maximum control over cable length
- Want to save money
- Have the time necessary to build cables

TP Wiring Standards

If you want to create twisted pair (TP) cables yourself, be sure your cable pairs match the color-coding of any existing cable or the color-coding of any prebuilt cabling you want to add to your new network. Because there are eight wires in TP cables, many incorrect combinations are possible. Several standards exist for UTP cabling.

Tip

The key is to be consistent and use the same scheme for all your cables and to ensure that anyone else working on your network understands the scheme used in it.

One common standard is the AT&T 258A configuration (also called EIA/TIA 568B). Table 20.6 lists the wire pairing and placement within the standard RJ-45 connector.

Table 20.6 RJ-45 Connector Wire Pairing and Placement for AT&T 258A/EIA 568B Standard

Wire Pairing	Wire Connected to Pin #	Pair Used For
White/blue and blue	White/blue - #5 Blue - #4	Not used[1]
White/orange and orange	White/orange - #1 Orange - #2	Transmit
White/green and green	White/green - #3 Green - #6	Receive
White/brown and brown	White/brown - #7 Brown - #8	Not used[1]

1. This pair is not used with 10BASE-T or Fast Ethernet 100BASE-TX, but all four pairs are used with Fast Ethernet 100BASE-T4 and Gigabit Ethernet 1000BASE-TX standards.

In Figure 20.16 you can see a RJ-45 cable connector wired to the EIA 568B/AT&T 258A standard.

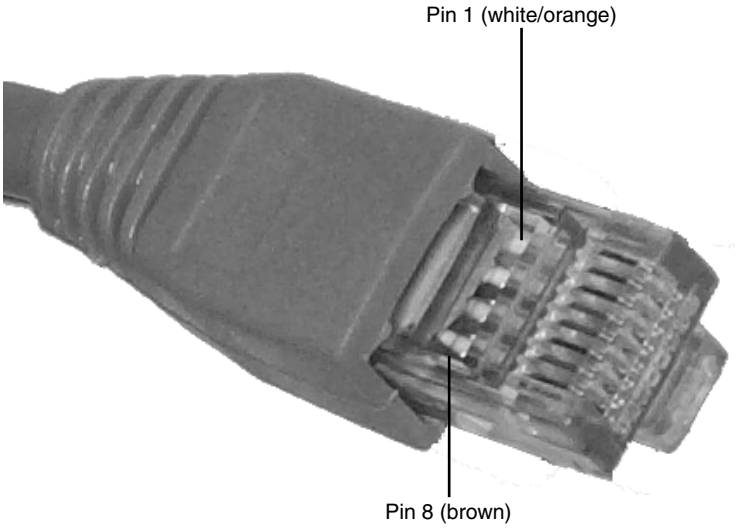

Figure 20.16 An AT&T 258A/EIA 568B standard compliant RJ-45 connector.

Note

You also might encounter the similar EIA 568A standard. It reverses the position of the orange and green pairs listed previously.

Crossover UTP Cables

Crossover cables, which change the wiring at one end of the cable, are used to connect two (and only two) computers together when no hub or switch is available or to connect a hub or switch without an uplink (stacking) port to another hub or switch. The pinout for a crossover cable is shown in Table 20.7. This pinout is for one end of the cable only; the other end of the cable should correspond to the standard TIA 568B pinout, as shown previously in Figure 20.16.

Table 20.7 RJ-45 Connector Wire Pairing and Placement for Crossover Variation on EIA 568B Standard

Wire	Pin #
White/blue	5
Blue	4
White/green	1
Green	2
White/orange	3
Orange	6
White/brown	7
Brown	8

Note

It should be noted that other wiring schemes exist, such as IEEE and USOC. All told, at least eight agreed-on standards exist for connecting UTP cables and RJ-45 connectors. The ones listed in this chapter are the most common.

Making Your Own UTP Cables

Making your own UTP cables requires a few tools that aren't commonly found in a typical toolbox. Those items that you might not already have you can typically purchase for a single price from many network-products vendors. You will need the following tools and supplies to build your own Ethernet cables (see Figure 20.17):

- UTP cable (Category 5 or better)
- RJ-45 connectors
- Wire stripper
- RJ-45 crimping tool

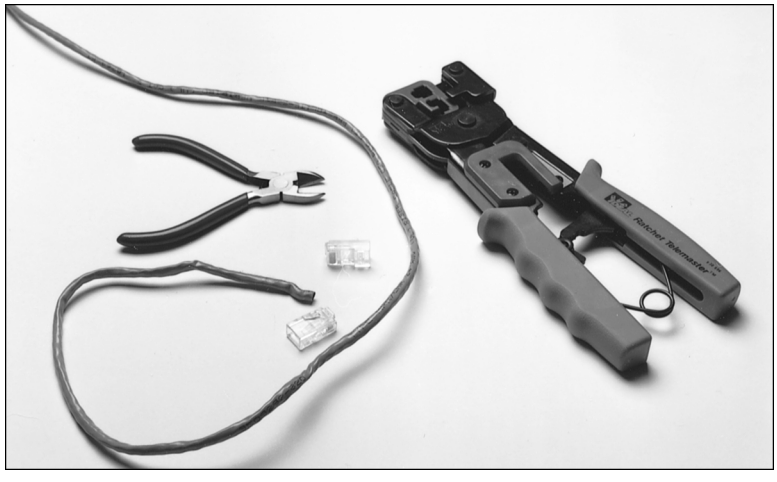

Figure 20.17 You'll need wire strippers, a crimping tool, bulk UTP cable, and RJ-45 connectors to make your own 10BASE-T (100BASE-T) cables.

Before you make a "real" cable of any length, you should practice on a short length of cable. RJ-45 connectors and bulk cable are cheap; network failures are not. Follow these steps for creating your own twisted-pair cables:

1. Determine how long your UTP cable should be. You should allow adequate slack for moving the computer and for avoiding strong interference sources. Keep the maximum distances for UTP cables listed later in this chapter in mind.
2. Roll out the appropriate length of cable.
3. Cut the cable cleanly from the box of wire.
4. Use the wire stripper to strip only the insulation jacket off the cable to expose the TP wires (see Figure 20.18); you'll need to rotate the wire about 1 1/4 turns to strip away all the jacket. If you turn it too far, you'll damage the wires inside the cable.

Figure 20.18 Carefully strip the cable jacket away to expose the four wire pairs.

5. Check the outer jacket and inner TP wires for nicks; adjust the stripper tool and repeat steps 3 and 4 if you see damage.
6. As shown in Figure 20.19, arrange the wires according to the EIA 568B standard. This arrangement is listed earlier in the chapter, in the section "TP Wiring Standards."
7. Trim the wire edges so the eight wires are even with one another and are slightly less than 1/2" past the end of the jacket. If the wires are too long, crosstalk (wire-to-wire interference) can result; if the wires are too short, they can't make a good connection with the RJ-45 plug.
8. With the clip side of the RJ-45 plug facing away from you, push the cable into place (see Figure 20.20). Verify that the wires are arranged according to the EIA/TIA 568B standard *before* you crimp the plug onto the wires (refer to Table 20.5 and Figure 20.16 earlier in this chapter). Adjust the connection as necessary.
9. Use the crimping tool to squeeze the RJ-45 plug onto the cable (see Figure 20.21). The end of the cable should be tight enough to resist being removed by hand.
10. Repeat steps 4–9 for the other end of the cable. Recut the end of the cable if necessary before stripping it.
11. Label each cable with the following information:

    - Wiring standard
    - Length
    - End with crossover (if any)
    - _____ (blank) for computer ID

Figure 20.19 Arrange the wire pairs for insertion into the RJ-45 connector according to your chosen scheme (EIA 568B for instance).

Figure 20.20 Push the RJ-45 connector into place, ensuring the cable pairs are ordered properly.

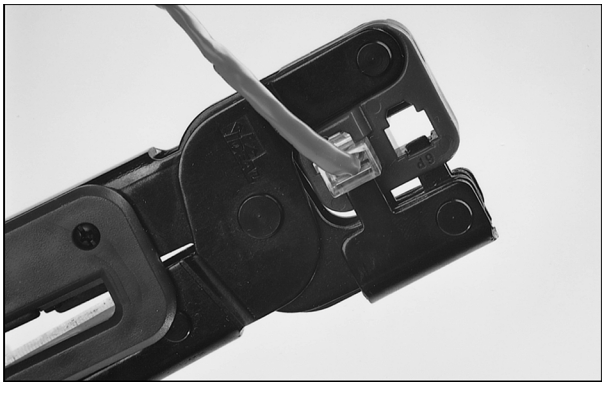

Figure 20.21 Firmly squeeze the crimping tool to attach the connector to the cable.

The cables should be labeled at both ends to make matching the cable with the correct computer easy and to facilitate troubleshooting at the hub. Check with your cable supplier for suitable labeling stock or tags you can attach to each cable.

An excellent online source for this process is `http://www.duxcw.com/digest/Howto/network/cable/`.

Cable Distance Limitations

The people who design computer systems love to find ways to circumvent limitations. Manufacturers of Ethernet products have made possible the building of networks in star, branch, and tree designs that overcome the basic limitations already mentioned. You can have thousands of computers on a complex Ethernet network.

LANs are local because the network adapters and other hardware components typically can't send LAN messages more than a few hundred feet. Table 20.8 lists the distance limitations of various types of LAN cable. In addition to the limitations shown in the table, keep the following points in mind:

- You can't connect more than 30 computers on a single Thinnet Ethernet segment.
- You can't connect more than 100 computers on a Thicknet Ethernet segment.
- You can't connect more than 72 computers on a UTP Token-Ring cable.
- You can't connect more than 260 computers on an STP Token-Ring cable.

Table 20.8 Network Distance Limitations

Network Adapter	Cable Type	Maximum	Minimum
Ethernet	10BASE-2	185m (607 ft.)	0.5m (1.6 ft.)
	10BASE-5 (drop)	50m (164 ft.)	2.5m (8.2 ft.)
	10BASE-5 (backbone)	500m (1,640 ft.)	2.5m (8.2 ft.)
	10BASE-T	100m (328 ft.)	2.5m (8.2 ft.)
	100BASE-TX	100m (328 ft.)	2.5m (8.2 ft.)
	1000BASE-TX	100m (328 ft.)	2.5m (8.2 ft.)
Token-Ring	STP	100m (328 ft.)	2.5m (8.2 ft.)
	UTP	45m (147 ft.)	2.5m (8.2 ft.)
ARCnet	Passive hub drop	30m (98 ft.)	Varies by cable type
	Active hub	600m (1,968 ft.)	Varies by cable type

If you have a station wired with Category 5 cable that is more than 328 feet (100 meters) from a hub, you must use a repeater. If you have two or more stations beyond the 328' limit of UTP Ethernet, connect them to a hub or switch that is less than 328 feet away from the primary hub or switch and connect the new hub or switch to the primary hub or switch via its uplink port. Because hubs and switches can act as repeaters, this feature enables you to extend the effective length of your network (see Figure 20.22).

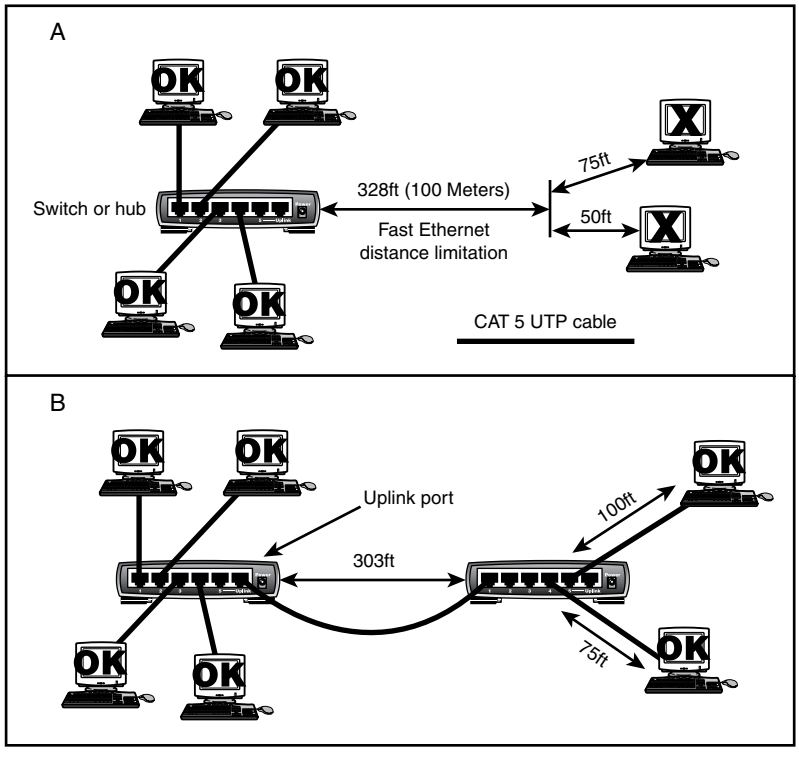

Figure 20.22 In case A (top), the workstations on the right are too far away from the hub to connect to a Fast Ethernet network. In case B (bottom), an additional hub or switch is used to allow the workstations to be added to the network.

Wireless Network Standards

Various forms of wireless networks using either radio or IR (infrared) have been developed over the years, but until recently, the benefits of a wireless network (no wires to pull or holes to drill) were outweighed by the lack of standards and relatively slow speed. In conventional Ethernet networks, you can use various brands of NICs, hubs, and switches without any problems, as long as each device corresponds to the same Ethernet standard.

Even though early forms of wireless networking were much slower than wired networks and often were single-vendor proprietary solutions, today's newest wireless networks offer speeds comparable to or faster than 10BASE-T wired networks and offer multivendor mix-and-match equipment sources. Prices have also dropped dramatically, making wireless networking an increasingly appealing alternative to traditional wired network solutions.

The most common forms of wireless networking include IEEE 802.11b (also called Wi-Fi) and HomeRF, with others (including other IEEE 802.11-based versions and the long-awaited Bluetooth standards) also vying for your attention.

Wi-Fi, the IEEE 802.11b Wireless Ethernet Standard

Wi-Fi (Wireless Fidelity) is the name used for IEEE 802.11b-compliant hardware that has passed the compatibility and interoperability tests of the trade group known as the Wireless Ethernet Compatibility Alliance (WECA); see its Web site at `www.wi-fi.org`.

Wi-Fi–compliant wireless networks run at a maximum speed of 11Mbps, about the same as 10BASE-T Ethernet (the original version of IEEE 802.11 supported data rates up to 2Mbps only). Other data rates Wi-Fi networks support include 1Mbps, 2Mbps, and 5.5Mbps. Wi-Fi networks can connect to conventional Ethernet networks or be used as independent networks, similar to other wireless networks. The major advantage of Wi-Fi networks is their interoperability; just as you can mix and match conventional Ethernet hardware, you should be able to mix and match Wi-Fi–compliant hardware on the same network.

Wireless networks running Wi-Fi hardware use the same 2.4GHz spectrum that many portable phones, wireless speakers, security devices, microwave ovens, and the now-emerging Bluetooth short-range networking products use. Although the increasing use of these noncomputer products is a potential source of interference, the short range of wireless networks (indoor ranges up to 300 feet and outdoor ranges up to 1,500 feet, varying by product) minimizes the practical risks, at least for the present.

Wi-Fi networks use two types of devices to connect via the 2.4GHz band:

- Access points
- NICs equipped with radio transceivers

An *access point* is a bookend-size device that uses an RJ-45 port to attach to a 10BASE-T or 10/100 Ethernet network (if desired) and contains a radio transceiver, encryption, and communications software. It translates conventional Ethernet signals into wireless Ethernet signals it broadcasts to wireless NICs on the network and performs the same role in reverse to transfer signals from wireless NICs to the conventional Ethernet network.

For coverage of a large area, purchase two or more access points and connect them to an Ethernet switch or hub. This enables users to "roam" inside a building without losing contact with the network. Some access points can communicate directly with each other via radio waves, enabling you to create a wireless backbone that can cover a wide area, such as a warehouse, without the need to run any network cabling.

Access points are not necessary for direct peer-to-peer networking (also called *ad hoc mode*), but they are required for a shared Internet connection or a connection with another network. When access points are used, the network is operating in the *infrastructure mode*.

NICs equipped for wireless Ethernet communications have a fixed or detachable radio antenna in place of the usual coaxial or RJ-45 port or dongle. Because a major market for wireless Ethernet use is notebook computer users, some vendors sell only PC Cards in their wireless Ethernet product lines, but most vendors support PCI cards for desktop computers. Several of these vendors now support the popular USB port. Because you can mix and match products, you can incorporate any mix of desktop and notebook computers into your wireless network. Figure 20.23 illustrates typical Wi-Fi network hardware.

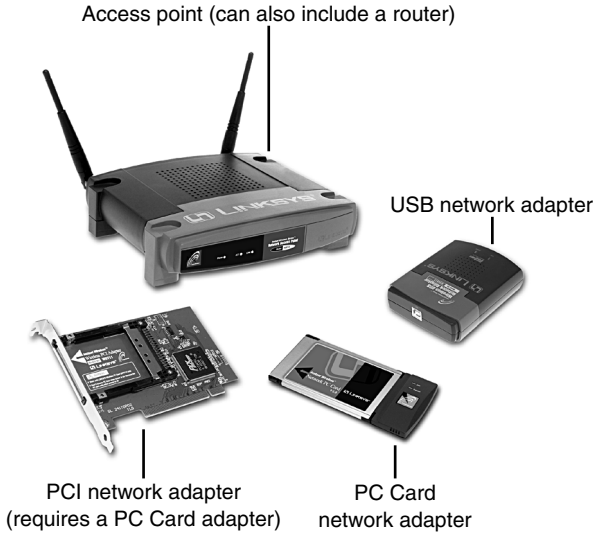

Figure 20.23 A typical family of Wi-Fi wireless products, including a wireless access point, USB, PC Card, and PCI wireless network adapters. The PC Card is used in notebook computers that lack Wi-Fi support and also acts as the transceiver for the PCI card used in desktop computers. *Photo courtesy of Linksys*.

Client systems lock onto the strongest signal from access points and automatically roam (switch) to another access point when the signal strength is stronger and the error level is lower than the current connection.

Security and Other Features

Because wireless networks could, in theory, be accessed by anyone with a compatible NIC, most models of NICs and access points provide for encryption options. Some devices with this feature enable you to set a security code known as an ESSID on the wireless devices on your network. This seven-digit code prevents unauthorized users from sneaking onto your network and acts as an additional layer of security along with your normal network authentication methods, such as user passwords. Others use a list of authorized MAC numbers (each NIC has a unique MAC) to limit access to authorized devices only. All Wi-Fi products support at least 40-bit encryption through the wired equivalent privacy (WEP) specification, but many vendors offer 128-bit encryption products. However, the stronger encryption feature is more common among enterprise products than small-office/home-office–oriented products. You should match the encryption level used on both the access points and the NICs for best security.

Some products' access points can be managed via a Web browser and provide diagnostic and monitoring tools to help you optimize the positioning of access points.

Many products feature support for Dynamic Host Configuration Protocol (DHCP), allowing a user to move from one subnet to another without difficulties.

Figure 20.24 illustrates how a typical IEEE 802.11b wireless network uses multiple access points.

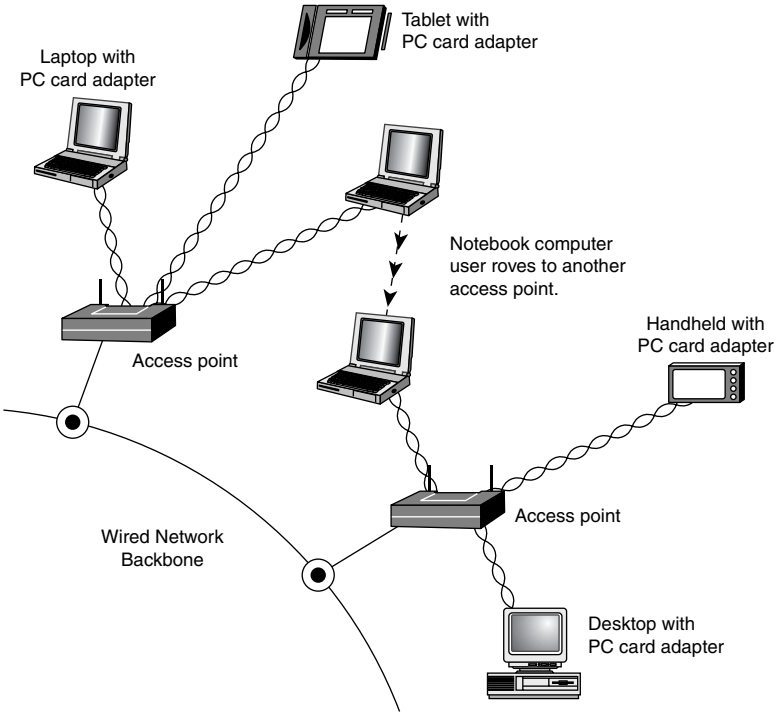

Figure 20.24 A typical wireless network with multiple access points. As users with wireless NICs move from one office to another, the roaming feature of the NIC automatically switches from one access point to another, permitting seamless network connectivity without wires or logging off the network and reconnecting.

Users per Access Point and Cost Issues

The number of users per access point varies with the product; Wi-Fi access points are available in capacities supporting anywhere from 15 to as many as 254 users. You should contact the vendor of your preferred Wi-Fi access point device for details.

Although workgroup network-in-a-box solutions that use 10/100 Ethernet (wired) technology can connect two PCs for around $80 ($40 per user) and additional network cards are available for under $20, Wi-Fi networking is far more expensive because of the high cost of access points and wireless NICs. For example, the Agere Systems/Lucent Orinoco AP-1000 access point has a selling price of about $650; each desktop computer requires a wireless PCI card (around $70) and a wireless PC Card (around $100); and each notebook computer requires a wireless PC Card (around $100). You can also use a USB adapter (around $160) with compatible desktop or notebook computers. The small-office-oriented Linksys Wireless Access Point Model WAP11 sells for about $155—its PCI cards are $45 each (plus the cost of a PC Card), its PC Cards are $107 each, and its USB devices are $109 each.

To determine the cost per user of a basic wireless network, use the following worksheet:

Cost Per Device		Number of Devices		Extended Cost
Cost Per Access Point		Number of Access Points		
_____	×	_____	=	_____
Cost Per PCI Card		Number of PCI Cards Needed		
_____	×	_____	=	_____
Cost Per PC Card		Number of PC Cards		
_____	×	_____	=	_____
Cost Per USB Port Device		Number of USB Port Devices		
_____	×	_____	=	_____
Total Cost of Network Hardware (TC)				_____
Total Number of PCI, PC Card, USB Devices (TN)			/	_____
Cost Per User (divide TC by TN)			=	_____

Typically, you can expect the cost per user of even the lowest-cost four-station Wi-Fi LAN to average between $170 and $312 (based on one access point, two PCI adapters with matching PC Card adapters, one PC Card adapter, and one USB adapter). Thus, the capability to roam with a notebook and avoid wiring problems must be very critical to make up for the much higher cost of wireless Ethernet networking when compared to basic (and obsolescent) 10BASE-T Ethernet networks (which have comparable performance to Wi-Fi). If you plan to use your Wi-Fi network to share a broadband Internet connection such as a cable modem or DSL line (as discussed in Chapter 19, "Internet Connectivity"), substitute a gateway (which combines a wireless access point with a router) for the normal access point.

Because Wi-Fi is a true standard, you can mix and match access point and wireless NIC hardware to meet your desired price, performance, and feature requirements for your wireless network, just as you can for conventional Ethernet networks.

Notebook Computers with Integrated Wi-Fi Adapters

Major notebook computer makers, including Dell, IBM, and Toshiba, are now integrating built-in Wi-Fi wireless adapters and antennas into some of their notebook computers. Although computers with built-in Wi-Fi hardware are a little more expensive than comparable models lacking Wireless Ethernet support, building the adapter and antenna into notebook computers provides for a more durable and less cumbersome way to equip portable systems than the normal PC Card and external antenna arrangement that must be fitted to ordinary notebook computers.

Most notebook computers with Wi-Fi hardware onboard use the mini-PCI interface for the wireless adapter and place the antenna inside the screen housing. This enables computers with built-in Wi-Fi hardware to have one more open PC Card slot than computers that must use an external PC Card adapter and antenna.

Alternatives to the IEEE 802.11b Standard

Although Wi-Fi/IEEE 802.11b wireless networking is the most common form of home and business-class wireless networking now on the market, you might prefer to consider other alternatives because of speed or other concerns.

The following wireless LANs use the same access point plus the wireless NIC design that the IEEE 802.11b networks discussed earlier in this chapter use:

- *RadioLAN Wireless MobilLINK*. Runs at speeds up to 10Mbps (but claims greater throughput than Wi-Fi) and uses the 5.8GHz radio frequency.
- *IEEE 802.11a*. Runs at speeds up to 54Mbps and uses the 5GHz frequency. Products using this standard are available from many vendors and are slightly more expensive than 802.11b/Wi-Fi hardware.
- *IEEE 802.11g*. Runs at speeds up to 54Mbps and uses the same 2.4GHz frequency as Wi-Fi/IEEE 802.11b. Products using this protocol are expected to ship in late 2002 and early 2003.

RadioLAN and IEEE 802.11a can't connect directly to Wi-Fi/IEEE 802.11b networks because they use different frequencies (a wired Ethernet bridge must be used). However, because IEEE 802.11g uses the same frequency as Wi-Fi/IEEE 802.11b, interoperability is expected to be possible after the first 802.11g hardware ships.

Other solutions can also be regarded as industry standards because multiple companies support them, although they use different technologies from the Ethernet-type wireless networks. These include

- Bluetooth
- HomeRF

Bluetooth is a low-speed (up to 400Kbps), low-power standard designed to interconnect notebook computers, PDAs, cell phones, and pagers for data synchronization and user authentication in public areas, such as airports, hotels, rental car pickups, and sporting events.

Bluetooth-compliant devices began to arrive on the market in the second half of 2000. A list of Bluetooth products and announcements is available at the official Bluetooth wireless information Web site: `www.bluetooth.com`. Bluetooth devices also use the same 2.4GHz frequency range Wi-Fi/IEEE 802.11b devices use. However, to avoid interference with Wi-Fi, Bluetooth uses a signaling method called *frequency hopping spread spectrum*, which switches the exact frequency used during a Bluetooth session 1,600 times per second over the 79 channels Bluetooth uses. Unlike Wi-Fi, which is designed to allow a device to be part of a network at all times, Bluetooth is designed for ad hoc temporary networks in which two devices connect only long enough to transfer data and then break the connection.

The HomeRF Consortium, headed by Proxim, has developed wireless products designed for home networking, using the Shared Wireless Access Protocol (SWAP).

Original HomeRF 1.2-compliant products ran at a leisurely 1.6Mbps, but the current HomeRF 2.0 standard supports speeds up to 10Mbps. HomeRF products can be interconnected with conventional Ethernet networks through the use of a cordless Ethernet bridge.

HomeRF-based products are available from Proxim (Symphony-HRF and Symphony HomeRF), Intel (AnyPoint Wireless), Motorola (AL 200 Wireless Cable Modem), Compaq (iPAQ Connection Point), and Cayman (3220-H-W Wireless Solution); the first 10Mbps HomeRF 2.0-compliant products were introduced by Proxim. Because HomeRF is based on the SWAP standard, you can mix and match products from different vendors. HomeRF products include

- *Cordless Ethernet bridges*. These are available from Symphony.
- *Wireless NICs for PC Card slots*. These are available from Intel, Symphony, and Compaq.
- *Wireless NICs for USB ports*. These are available from Intel and Compaq.
- *Specialized devices*. These are devices such as the multiple-network-compatible iPAQ Connection Point (supports 10/100 Ethernet, HomeRF, Phoneline HomePNA 2.0, and 56Kbps modems) and Cayman's 3220-H-W DSL gateway.

Although the 1.6Mbps performance of HomeRF 1.2 is far lower than that of IEEE 802.11b–based products, the cost for one or two users is much lower because HomeRF-based products connect directly with each other. HomeRF 2.0 devices run at 10Mbps and are still much less expensive than Wi-Fi devices because no dedicated access point is required.

For example, Symphony's HomeRF 2.0 USB and PC Card adapters are about $100 each, whereas the HomeRF Base Station (which connects the network to a broadband Internet device) is about $200. HomeRF products also use the same 2.4GHz frequency used by IEEE 802.11b and Bluetooth wireless products, which could cause interference between devices, although these products are typically used in different environments. Bluetooth uses a frequency-hopping spread-spectrum transmission method to reduce the likelihood of interference with other 2.4GHz networks and wireless devices such as cordless phones.

Wireless Network Logical Topologies

Wireless networks have different topologies, just as wired networks do. However, wireless networks use only two logical topologies:

- *Star*. The star topology, used by Wi-Fi/IEEE 802.11b–based products in the infrastructure mode and RadioLAN, resembles the topology used by 10BASE-T and faster versions of Ethernet that use a hub. The access point takes the place of the hub because stations connect via the access point, rather than directly with each other. This method is much more expensive per unit but permits performance near 10BASE-T Ethernet speeds and easier management.
- *Point-to-Point*. HomeRF and Bluetooth products (as well as Wi-Fi products in the *ad hoc* mode) use the point-to-point topology. These devices connect directly with each other and require no access point or other hub-like device to communicate with each other, although shared Internet access with HomeRF does require that all computers connect to a common wireless gateway. The point-to-point topology is much less expensive per unit than a star topology. It is, however, suited to very small, simple networks (HomeRF home networks) or for temporary data sharing with another device (Bluetooth) and is currently much slower than 100BASE-TX networks.

Figure 20.25 shows a comparison of wireless networks using these two topologies, and Table 20.9 compares the major wireless network standards in current use.

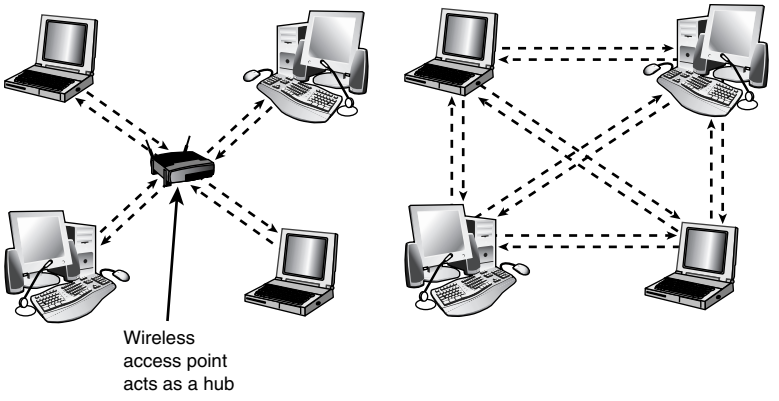

Figure 20.25 A logical star topology (left) as used by IEEE 8.02.11–based wireless Ethernet compared to a point-to-point topology as used by HomeRF and Bluetooth (right).

Table 20.9 Comparison of Current Wireless Networks

Network	Rated Speed	Logical Topology	Connects with 10BASE-T Ethernet via	Maximum Number of PCs Per Access Point	Average Cost Per User[6]
IEEE 802.11a	54Mbps	Logical Star (requires access point)			
IEEE 802.11b Wi-Fi	11Mbps	Logical Star (requires access point)	Access point	Varies by brand and model; up to 256 or more	$315[1, 3]; $170[2, 3]
RadioLAN	10Mbps[4]	Logical Star (requires access point)	Wireless BackboneLINK (access point)	128	$564[3]
HomeRF[5]	1.6Mbps (1.2) 10Mbps (2.0)	Point-to-Point	Symphony Cordless Ethernet Bridge	N/A	$134
Bluetooth	Approx. 400Kbps	Point-to-Point	N/A	N/A	Varies[7]

1. Average price of enterprise-level products from Agere Systems/Lucent (Orinoco AP-1000) as of 4Q2001.

2. Average price of small-office-level products from Linksys (Instant Wireless WAP-11) as of 4Q2001.

3. Price includes access point (required for connection to other networks).

4. The actual throughput of RadioLAN compared to average of IEEE 802.11b products is about 25% faster because of the higher radio frequency used.

5. Figures for Proxim Symphony, first HomeRF product available.

6. Average cost per user based on a four-station network with two PCI desktop and two notebook PCs and one access point if needed.

7. Bluetooth is implemented as an embedded network feature in many non-PC devices as well as in PCs.

Network Protocols

The second-most important choice you must make when you create your network is which network protocol to use. The network protocol affects which types of computers your network can connect.

The three major network protocols are TCP/IP, IPX/SPX, and NetBEUI. Unlike data-link protocols, though, network protocols are not tied to particular hardware (NIC or cable) choices. Network protocols are software and can be installed to or removed from any computer on the network at any time as necessary. Table 20.10 summarizes the differences between these protocols.

Table 20.10 Overview of Network Protocols and Suites

Protocol	Included in Protocol Suite	Best Used for	Notes
IP	TCP/IP	Internet and large networks	Also used for dial-up Internet access; native protocol suite of Windows 2000 and XP and Novell NetWare 5.x and 6.x
IPX	IPX/SPX	Networks with Novell 4.x and earlier servers	Used by NetWare 5.x for certain special features only
NetBEUI	N/A	Windows 9x, 2000, or Windows for Workgroups peer networks	Can't be routed between networks; simplest network protocol; also used with Direct Cable Connection NIC-less "networking"; not supported in Windows XP, but can be installed manually from the Windows XP CD-ROM for troubleshooting

All the computers on any given network must use the same network protocol or protocol suite to communicate with each other.

IP and TCP/IP

IP stands for Internet Protocol; it is the network layer of the collection of protocols (or protocol suite) developed for use on the Internet and commonly known as TCP/IP (Transmission Control Protocol/Internet Protocol).

Later, the TCP/IP protocols were adopted by the Unix operating systems, and they have now become the most commonly used protocol suite on PC LANs. Virtually every operating system with networking capabilities supports TCP/IP, and it is well on its way to displacing all the other competing protocols. Novell NetWare 6 and Windows XP both use TCP/IP as their native protocol for most services.

TCP/IP—LAN and Dial-Up Networks

TCP/IP, unlike the other network protocols listed in the previous section, is also a protocol used by people who have never seen a NIC. People who access the Internet via modems (with what Windows 9x calls Dial-Up Networking) use TCP/IP just as those whose Web access is done with their existing LANs. Although the same protocol is used in both cases, the settings vary a great deal.

Table 20.11 summarizes the differences you're likely to encounter. If you access the Internet with both modems and a LAN, you must ensure that the TCP/IP properties for modems and LANs are set correctly. You also might need to adjust your browser settings to indicate which connection type you are using. Table 20.11 provides general guidelines; your ISP or network administrator can give you the specific details.

Table 20.11 TCP/IP Properties by Connection Type—Overview

TCP/IP Property Tab	Setting	Modem Access (Dial-Up Adapter)	LAN Access (Network Card)
IP Address	IP Address	Automatically assigned by ISP	Specified (get value from network administrator)
WINS Configuration	Enable/Disable WINS Resolution	Disabled	Indicate server or enable DHCP to allow NetBIOS over TCP/IP
Gateway	Add Gateway/ List of Gateways	None (PPP is used to connect modem to Internet)	IP address of gateway used to connect LAN to Internet
DNS Configuration	Enable/Disable Host Domain	Usually disabled, unless proxy server used by ISP	Enabled, with host and domain specified (get value from network administrator)

As you can see from Table 20.11, correct settings for LAN access to the Internet and dial-up networking (modem) settings are almost always completely different. In general, the best way to get your dial-up networking connection working correctly is to use your ISP's automatic setup software. This is usually supplied as part of your ISP's signup software kit. After the setup is working, view the properties and record them for future troubleshooting use.

Note

In Windows 98 and Me, Microsoft recommends that TCP/IP properties be viewed through the Dial-Up Networking icon for the connection, rather than through the Network icon in the Control Panel. This is because different dial-up connections could use different TCP/IP properties, which would override the default properties for the Dial-Up Adapter listing in the Network properties.

IPX

The IPX protocol suite (often referred to as IPX/SPX) is the collective term for the proprietary protocols Novell created for its NetWare operating system. Although based loosely on some of the TCP/IP protocols, Novell privately holds the IPX protocol standards. However, this has not prevented Microsoft from creating its own IPX-compatible protocol for the Windows operating systems.

IPX (Internetwork Packet Exchange) itself is a network layer protocol that is equivalent in function to IP. The suite's equivalent to TCP is the Sequenced Packet Exchange (SPX) protocol, which provides connection-oriented, reliable service at the transport layer.

The IPX protocols typically are used today only on networks with NetWare servers running older versions of NetWare and often are installed along with another protocol suite, such as TCP/IP. Novell has phased out its use of IPX for NetWare support and switched to TCP/IP—along with the rest of the networking industry—starting with NetWare 5. NetWare 5 uses IPX/SPX only for specialized operations. Most of the product uses TCP/IP. NetWare 6, the latest version of NetWare, uses TCP/IP exclusively.

NetBEUI

NetBIOS Extended User Interface (NetBEUI) is a protocol used primarily on small Windows NT networks, as well as on peer networks based on Windows for Workgroups and Windows 9x. It was the default protocol in Windows NT 3.1, the first version of that operating system. Later versions, however, use the TCP/IP protocols as their default.

NetBEUI is a simple protocol that lacks many of the features that enable protocol suites such as TCP/IP to support networks of almost any size. NetBEUI is not routable, so it can't be used on large internetworks. It is suitable for small peer-to-peer networks, but any serious Windows NT/2000/XP network installation should use TCP/IP.

NetBEUI is still useful for creating "instant networks" with the Direct Cable Connection (see the following), and it is the minimum protocol required for use in a Windows 9x peer-to-peer network.

Other Home Networking Solutions

If you are working at home or in a small office, you have an alternative to hole-drilling; pulling specialized network cabling; and learning how to configure TCP/IP, IPX, or NetBEUI protocols.

So-called "home" networking is designed to minimize the complexities of cabling and protocol configuration by providing users with a sort of instant network that requires no additional wiring and configures with little technical understanding.

HomePNA

Other than using Ethernet, the most popular form of home networking involves adapting existing telephone wiring to networking by running network signals at frequencies above those used by the telephone system. Other, less popular forms of home networking piggyback on household or office electrical wiring or are wireless, taking advantage of previously unused parts of the electromagnetic spectrum.

Because it is the most developed and most broadly supported type of home networking, this discussion focuses on the HomePNA standards the Home Phoneline Networking Alliance (`http://www.homepna.org`) has created. This alliance has most of the major computer hardware and telecommunications vendors among its founding and active membership.

A companion Web site focusing on products that use HomePNA standards is `http://www.homepna.com`.

The Home Phoneline Networking Alliance has developed two versions of its HomePNA standard. Both versions are designed to work over existing telephone lines, but they have big differences in speed and hardware usage.

HomePNA 1.0

The original HomePNA standard, introduced in 1998, was designed to make home networking as much of a no-brainer as possible. HomePNA 1.0 has a speed of just 1Mbps, which is just 1/10 the speed of 10BASE-T or other forms of standard Ethernet. HomePNA 1.0 was designed for ease of

use—rather than performance—and utilized parallel ports, USB ports, and PCI cards for use with desktop computers, and PC Card (PCMCIA) devices for use with notebook computers. HomePNA 1.0 is now obsolete, having been replaced by HomePNA 2.0; HomePNA 1.0 products can be used on the same network as HomePNA 2.0 products.

HomePNA 2.0

HomePNA 2.0–compatible products began to appear in late 1999. HomePNA 2.0 runs up to 10Mbps, making it comparable to standard Ethernet speeds, and is implemented through 32-bit PCI network cards for desktop computers and PC Card devices for use with notebook computers (see Figure 20.26). The newest HomePNA 2.0–compatible devices include broadband modems, Internet appliances, and broadband gateways. Some home-office computers include HomePNA 2.0 interface cards.

HomePNA 2.0–compatible products are fast enough to make Internet connection sharing a workable reality and are backward-compatible with HomePNA 1.0 products.

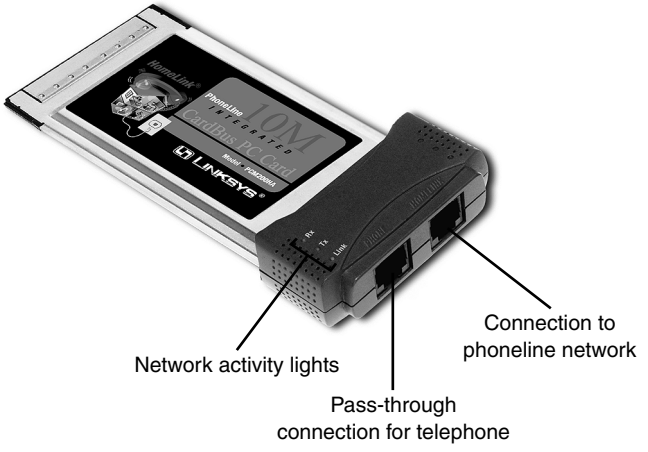

Figure 20.26 A typical HomePNA 2.0 PC Card network adapter from Linksys. *Photo courtesy of Linksys.*

After HomePNA network adapters are installed, they use the same network protocols as do other adapters. A default installation might install only the nonrouteable NetBEUI protocol, but if you use your HomePNA network to share an Internet connection (see Figure 20.27 in the following section), you will also need to install the TCP/IP protocol on each computer if it is not already installed. See the documentation for your HomePNA router for details on installation and client configuration.

HomePNA Topology

HomePNA uses a simplified form of the bus topology described earlier in this chapter. The telephone wiring is the backbone of a HomePNA network, and each HomePNA network adapter has two connectors: one that connects to the telephone wiring in the wall and another that enables you to plug a telephone into the adapter and use the phone at the same time as the network is active. This passthrough feature is similar to that found on most telephone modems. Figure 20.27 illustrates a typical HomePNA network being used to share a broadband Internet connection.

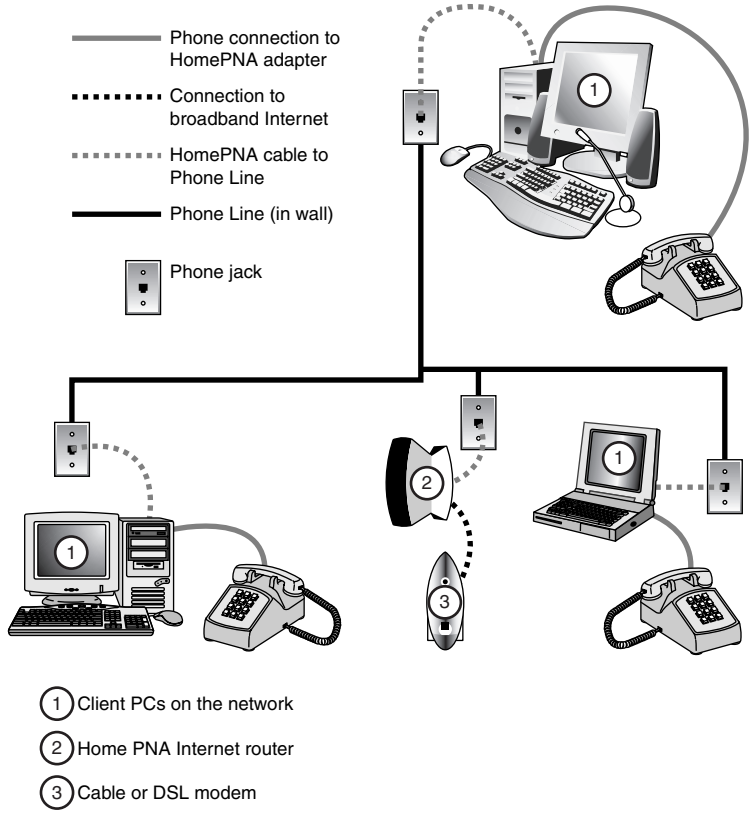

Figure 20.27 A typical HomePNA network with three stations; this network enables data and peripheral sharing and shared access to a broadband Internet cable or DSL modem.

▶▶ For more information about sharing Internet access and broadband Internet devices, see Chapter 19, "Internet Connectivity," p. 1041.

Powerline Networking

Home networking via power lines has been under development for several years, but electrical interference, inconsistent voltage, and security issues made the creation of a workable standard difficult until mid-2001. In June 2001, the HomePlug Powerline Alliance, a multivendor industry trade group, introduced its HomePlug 1.0 specification for 14Mbps (40% faster than 10BASE-T Ethernet) home networking using power lines. The HomePlug Powerline Alliance conducted field tests in about 500 households early in 2001 to develop the HomePlug 1.0 specification.

HomePlug 1.0 is based on the PowerPacket technology developed by Intellon. PowerPacket uses a signaling method called orthogonal frequency division multiplexing (OFDM), which combines multiple signals at different frequencies to form a single signal for transmission. Because OFDM uses multiple frequencies, it can adjust to the constantly changing characteristics of AC power. To provide security, PowerPacket also supports 56-bit DES encryption and an individual key for each home network. By using PowerPacket technology, HomePlug 1.0 is designed to solve the power quality and security issues of concern to a home or small-office network user.

The first HomePlug 1.0 products include USB adapters, bridges, and routers, enabling most recent PCs with USB ports to use powerline networking for LAN and Internet sharing. Linksys was the first to introduce HomePlug 1.0 products in late 2001.

The major rival to HomePlug, Inari (formerly Intelogis, which pioneered powerline networking with its Passport parallel-port network adapter), offers both 2Mbps and 12Mbps powerline networking solutions using a different technology from HomePlug. Inari's products—which are distributed by Thompson Multimedia, HP, and others—are not compatible with the HomePlug Powerline Alliance standards.

It's still too early to recommend powerline networks for use in a home or small-office network, although the development of a multivendor standard in 2001 helps to establish this type of networking as a future choice.

Home Networking Compared to Ethernet UTP Solutions

The pricing of home networks is comparable to Ethernet UTP solutions, but which one is best for you? Use Table 20.12 to determine which way to go in networking your small office or home office. Networks are listed in order of speed, from slowest to fastest.

Table 20.12 Comparing Wired and Wireless Home Networking Adapters to Ethernet UTP Networking—Adapters

Network Type	Cable Type	USB?	PCI Card?	ISA Card?	Notebook PC Card?	Speed
Ethernet 10BASE-T	UTP	Yes	Yes	Yes	Yes	10Mbps
HomePNA 2.0	Phone	Yes	Yes	No	Yes	10Mbps
HomeRF 2.0	Wireless	Yes	Yes	No	Yes	10Mbps
Wi-Fi	Wireless	Yes	Yes	No	Yes	11Mbps
HomePlug 1.0	Power	Yes	No	No	No	14Mbps
Fast Ethernet 100BASE-TX	UTP	Yes	Yes	No	Yes	100Mbps

In addition to speed and cable types, consider the issue of interconnecting a HomePNA network to a standard Ethernet network. You'll need a special PC Card or a HomePNA/Ethernet hub to interconnect the two networks, and some products of this type support only HomePNA 1.0 1Mbps speeds. You can't simply install HomePNA networking software onto a system that already has standard networking software installed; they aren't designed to coexist unless you use these types of dual-purpose hardware.

I recommend HomePNA 2.0–compatible networking for use only in a home-office environment in which technical expertise is scant and installing UTP wiring is out of the question. With the current rock-bottom pricing of Fast Ethernet 100BASE-TX NICs and hubs, Fast Ethernet is very close to the pricing of HomePNA 2.0 products, offers 10 times the speed, and has compatibility with a broad range of network protocols. HomePlug 1.0 is a new networking standard with limited vendor support, so I recommend that you wait until several vendors offer HomePlug-compliant products before adopting it.

Putting Your Network Together

You've bought or built your cables, bought your NICs and hub, and located your Windows CD-ROM. Now it's time to make your network a reality!

In this section is a detailed checklist of the hardware and software you need to build your network.

First, start with the number of computers you plan to network together. You need the items discussed in the following sections to set up your network.

Network Adapter

You need a network adapter for every computer on the network that doesn't have a network port already included; if the computer has a built-in network port, be sure the port type will work with your network.

Traditionally, network adapters are also called NICs, but the widespread use of USB devices and built-in ports makes this term less accurate. To simplify technical support, buy the same model of NIC for each computer in your network (if possible). If you are creating a Windows NT/2000/.NET or Novell NetWare network with a dedicated server, you should buy server-optimized NICs for the server and less-expensive client NICs for the client PCs. However, you should still purchase the same brand to simplify support issues. Some vendors use the same driver for both their server and client NICs, further simplifying your support issue.

For the best performance, I recommend that you use PCI-based NICs for desktop computers or PC Card CardBus NICs for notebook computers with CardBus slots (CardBus and PCI slots have a 32-bit wide data bus, whereas typical PC Card slots have a 16-bit data bus). USB devices are more convenient, but USB 1.1 devices are much slower than 10/100 Ethernet. USB 2.0 devices are a satisfactory substitute for 10/100 Ethernet but require that both the computer and the device be USB 2.0-compliant to achieve the 480Mbps speed of USB 2.0. If either the device or the computer is only USB 1.1-compliant, the connection is limited to 12Mbps.

You should record the brand name and model number of the network adapters you are using, as well as the driver version or source. Use Table 20.13 in the "Recording Information About Your Network" section, later in this chapter, as a template for storing this information.

Installing the Network Adapter

Before you can connect computers to the network, you must install network adapters. If the network adapter is an internal card, follow this procedure:

1. Open the case and locate an open expansion slot that matches the type of NIC you purchased (preferably PCI).
2. Using a screwdriver, remove the screw securing the slot cover at the rear of the case.
3. Insert the card gently, ensuring that the edge connector is seated solidly in the slot.
4. Fasten down the card with the same screw that held the slot cover.

▶▶ See Figures 23.28 and 23.29 in Chapter 22, "Building or Upgrading Systems," p. 1217, for an example of installing an add-on card.

Tip

If you are a realist like me, you might not want to close the case until you are certain the NIC is working (see the next section, "Testing Your Network Adapters and Connections").

A NIC uses the same hardware configuration settings most other expansion cards use:

- An IRQ
- An I/O port address range

Note

Some older network cards might require an upper memory block range for RAM buffers. Cards used on diskless workstations use a boot ROM, which also requires an upper memory block range. See your network card's documentation to find out whether this issue applies to you.

If you are using Windows 9x, Me, 2000, or XP with a PnP (Plug and Play) BIOS and a PnP NIC, the computer and Windows configure your card for you in most cases. In a few cases, you might need to adjust PnP settings in the BIOS, and in a rare case you might even need to remove your other PnP cards and put the NIC in first if your system doesn't recognize it after you restart the system.

▶▶ For general BIOS information, see Chapter 5, "BIOS," p. 355, or see your system manual for details about your computer's BIOS.

Even if you are installing a standard Ethernet 10BASE-T system, use PCI NICs whenever possible (you'll need to use PCI NICs for faster versions of Ethernet on desktop computers). As you saw earlier in this chapter, PCI is faster than ISA by a wide margin.

If you install the card in a non-PnP system or under Windows NT, be sure the card comes with configuration software or manual switch settings for hardware configuration. A pure PnP card can't be installed on a system that lacks PnP support.

USB and PC Card/CardBus network adapters are automatically detected and installed when connected because USB ports and PC Card/CardBus slots are hot-swap connections.

And, if you are using an older network adapter with the newest version of Windows—Windows XP—you might need to download drivers from the adapter vendors' Web sites. Even if you have drivers for your current version of Windows, getting the latest driver release will help you avoid setup and installation problems.

Testing Your Network Adapters and Connections

The configuration software disk or CD-ROM included with the network adapter usually features diagnostic software. Some diagnostics should be performed before the card is connected to the network and should be run from a command prompt.

After the network adapter passes these tests, connect the network adapter to the network. With an Ethernet network using UTP cable, run the cable from the card to the hub or switch, turn on the computer and hub, and watch for signal lights to light up on the NIC's back bracket (if so equipped) and on the hub or switch. Hubs and switches use green LEDs to indicate the presence of a computer on a particular RJ-45 port. Connect a second computer with NIC installed to the hub or switch. Then, run the diagnostics program on both computers to send and receive data. For other types of networks, see the diagnostics provided with the network hardware for testing details.

Cables and Connections Between Computers

Depending on the network you choose, you might need to run cables. If you are installing a 10BASE-T, 100BASE-TX, or 1000BASE-TX Ethernet network (all of which use UTP cables), you need cables that are long enough to reach comfortably between each computer's network port and the network's hub or switch. Use Table 20.13 in the "Recording Information About Your Network" section, later in this chapter, as a template for storing this information.

Because HomePNA networks are based on your existing telephone line, the patch cord included with the NIC is usually long enough to connect with your existing RJ-11 telephone jack. The HomePNA NIC has two jacks: one for the connection to the telephone line and the other to enable you to connect your telephone to the NIC. Be sure you use the correct jack for each cable; otherwise, your network won't work. HomePNA enables you to use your telephone system for voice and networking at the same time.

Wireless network NICs use an external antenna to make the connection between computers.

Hub/Switch/Access Point

UTP Ethernet networks require a hub or switch if more than two computers will be networked (you can use a crossover cable between two computers only). Wireless Ethernet networks also require an access point if more than two computers will be networked, or if the network will be used to share an Internet connection.

For a UTP-based Ethernet network, buy a hub or switch (preferred) of the correct speed with at least enough RJ-45 ports for each computer on the network. For a wireless Ethernet network, you will need at least one access point, depending on the range of your wireless network. Most IEEE 802.11b/Wi-Fi network access points have a range of 300 feet indoors (and up to 1,500 feet outdoors), which should be adequate for most homes and many small businesses. You can add more access points if you need a wider area of coverage.

If you are going to use the network to share Internet access, you can save money if you buy a router that contains a switch for a wired Ethernet network or a wireless access point that contains a router for a wireless Ethernet network.

Use Table 20.13 in the "Recording Information About Your Network" section, later in this chapter, as a template for storing this information. Table 20.13 also provides a space for recording whether you plan to use the network for Internet sharing.

Gateways for Non-Ethernet Networks

If you plan to share Internet access through a nonEthernet network such as HomePNA, HomeRF, or HomePlug and you don't want to use a software sharing solution such as Microsoft Internet Connection Sharing, you must install a gateway or router between the broadband device (such as a cable or DSL modem) and your network. Some gateway/router devices can also act as print servers; in addition, some, such as the 2Wire HomePortal 100 series, support HomePNA, Ethernet, or Wi-Fi networks.

Recording Information About Your Network

Networks are terrific when they work, but they're a potential nightmare when they fail. By keeping careful notes about network configuration, you can reinstall network drivers, set up new computers on the network, and handle other network crises without breaking a sweat.

Use the worksheet shown in Table 20.13 as a guide for recording information about your network hardware.

Table 20.13 Network Hardware Worksheet

Network Type	Number of Stations	Internet Sharing
_____	_____	_____

NIC Location and Computer ID	Brand Name	Model #	Cable Type(s)	Speed	Driver Source or Version
_____	_____	_____	_____	_____	_____

Computer ID	Cable Length	Wiring Standard
_____	_____	_____

Hub #	Brand	Model#	# of Ports	Uplink?	Speed(s)
_____	_____	_____	____	_____	_____

Router	Gateway	Model #	# of Ports	Speed(s)
_____	_____	_____	_____	_____

Router IP Address	Router Password
_____	_____

Installing Networking Software

To access network resources with a PC—whether it is connected to a client/server or peer-to-peer network—you must install network client software on the computer. The network client can be part of the operating system or a separate product, but it is this software that enables the system to use the network interface adapter to communicate with other machines.

On a properly configured network workstation, accessing network resources is no different from accessing local ones (except that they might be slightly slower). You can open a file on a network drive just as you would open the same file on your local hard disk. This is because the network client software is completely integrated into every level of the computer's operating system.

In most cases, the network client software is part of the operating system. Windows 9x, NT, 2000, and XP, for example, include all the software you need to participate in a peer-to-peer Windows network or to connect to Windows NT, Windows 2000, .NET, and Novell NetWare servers. To connect to a network using DOS or Windows 3.1, however, you must install a separate client software package.

When you install a NIC under Windows 95 or Windows 98, the following network protocols are installed by default:

- NetBEUI
- TCP/IP
- IPX/SPX

Windows Me, Windows 2000, and Windows XP use TCP/IP by default. If you need to install particular protocols or other network components, use the Networks icon in the Windows Control Panel or right-click the Network Neighborhood (Windows 9x) or My Network Places (Windows Me/2000) icon on the Windows desktop and select Properties.

Configuring Your Network Software

You might have a few problems installing your NICs. They might pass their diagnostics flawlessly, but until each station on your network can speak the same language, has correct client or server software setups, and uses the same protocols, your network will not function properly.

Table 20.14 shows the minimum network software configuration you must install for Windows 9x/Me, Windows NT, and Windows 2000 peer-to-peer networking.

Table 20.14 Minimum Network Software for Peer-to-Peer Networking

Item	Workstation	Server
Windows Network client	Yes	No
NetBEUI protocol	Yes	Yes
File and print sharing for Microsoft Networks	No	Yes
NIC installed and bound to protocols and services above	Yes	Yes
Workgroup identification (same for all PCs in workgroup)	Yes	Yes
Computer name (each PC needs a unique name)	Yes	Yes

Although the networking settings in Table 20.14 enable a Windows peer-to-peer network to function, you might need to add more networking components. If the computer can access a Novell NetWare client/server network running NetWare 4.x, the IPX/SPX protocol must also be installed. It also might be required for certain operations with NetWare 5. If the computer is used to access the Internet or any other TCP/IP-based network, the TCP/IP protocol must also be installed. In most cases, you can now use TCP/IP as the only network protocol because it can be used for both Internet and LAN access.

Use the Network icon in the Windows Control Panel to select your network settings. To set up your network, you'll need the operating system CDs, disks, or hard-disk image files and the network adapter drivers. (Workgroup hubs and switches require no software.)

To install a network component, follow this procedure:

1. Open the Network icon in the Control Panel.
2. The Configuration tab is displayed; select Add.
3. Select from the following:
   - *Client*. Select if you want to install the Microsoft or other network clients for your network. Every PC on a peer-to-peer network needs the Client for Microsoft Networks.
   - *Adapter*. This should already be installed, but you can use this to install a new adapter.

- *Protocol*. For a simple, non-Internet network, install NetBEUI. If you want to use Internet Connection Sharing along with networking, install both TCP/IP and NetBEUI.
- *Service*. Install File and Printer Sharing for Microsoft Networks on any computer that will be used as a server.

4. Click the Identification tab. Enter a unique name for each computer on the network; use the same workgroup name for all computers on the network.
5. Click OK. Supply the Windows CD-ROM or other media as necessary to install the network components you requested.
6. You are prompted to insert a CD or disk or browse to the appropriate files during the installation procedure, if they're not available on the Windows 9x CD-ROM or on your hard disk in the default location.

You might need to reboot your PC to complete the process, particularly if you're using Windows 9x or Me. After this is completed, you'll be ready to share resources.

After the network hardware and software installation is complete, your network is ready to use. However, if you are using Windows NT, Windows 2000, or Windows XP Professional, you must set up users and groups for security. Windows 9x and Me use peer-to-peer access control, which can be protected with passwords if you desire.

For more information about these processes, see "Configuring Users, Groups, and Resources" in the Technical Reference section of the DVD packaged with this book.

Tips and Tricks

Network configuration can take a long time unless you have a few tricks up your sleeve. Use this section to help you find faster, easier, and better ways to set up and use your network.

Installation

- If you are setting up several systems with identical hardware, NICs, and software, consider making an image file of the first system after you complete its installation with a program such as Drive Image Professional and then connecting the other computers and "cloning" the first computer's hard disk to each additional system. Check with the imaging software vendor for details.
- Don't click OK in the Windows Networks properties sheet until you have made all the changes you want to make (see the previous list) on a Windows 9x or Me system. Whenever you click OK, you are prompted to reboot the system to apply the changes.
- If you're salvaging old 10BASE-T Ethernet cards for a network, use Category 5 UTP and dual-speed hubs to make switching to Fast Ethernet in the future easier.

Sharing Resources

- If you want to have network drives or folders show up as part of My Computer so you can search them and see them easily in Windows Explorer, map a drive letter to each one. This step is desirable with any combination of operating systems and is a virtual necessity on networks in which Windows 2000 or Windows XP computers are accessing shared resources on a Windows 9x computer. Browsing the network is very slow without mapped drives, but access to shares through a mapped drive letter is very fast.

- To more easily keep drive mappings straight, I use the drive letter I plan to use for mapping on other workstations as the name of the shared resource on my peer server. In other words, if I want to map the D: drive on my peer server as "P:", I name it "P" when I set its sharing properties. Then, as I view the folder from another computer, I know from its name that I should map it as "P:". This enables multiple PCs to easily map the same resource as the same drive letter on different systems, which makes it easier if people in your office play musical computers.

Setting Up Security

- If you're building a peer-to-peer network, keep in mind that passwords are the only way to keep unwanted users out of your system.
- Create a group of several users and assign rights on a group basis when you have several users who need the same access rights.

Sharing Internet Connections

- If you are planning to share an Internet connection using Microsoft Internet Connection Sharing or other computer-based sharing programs, *don't* set up File and Printer Sharing on the computer that does the sharing (the proxy server or gateway computer). See Chapter 19 for software you can add to your computer to keep it safe on the Internet.
- Routers and gateway devices are an economical way to share broadband access in a home or small office, and they are easier to manage and more reliable than using ICS or other sharing programs. Routers and gateways can also act as firewalls to protect your computer from unauthorized access from the Internet.

Direct Cable Connections

Direct Cable Connection is a technology that enables you to connect two PCs together via their serial, parallel, or IR ports to make an instant network. Windows 9x, Me, 2000, and XP all include Direct Connect client and server software, but special parallel (preferred) or serial cables are required; IR (infrared) ports on notebook computers can also be used for direct connections. See the section "Direct Cable Connections" in Chapter 19, "Local Area Networking," of *Upgrading and Repairing PCs, 12th Edition*, included on this book's DVD, for details.

Troubleshooting a Network

The following sections list a series of common networking problems along with solutions that can usually set things right again.

Network Software Setup

Problem

Duplicate computer IDs.

Solution

Make sure that every computer on the network has a unique ID (use Control Panel, Network, Identification to view this information). Otherwise, you'll get an error message when you reboot the workstations with networking cables attached.

Problem

Different workgroup names.

Solution

Make sure every computer that's supposed to be working together has the same workgroup name. The Windows 9x/NT Network Neighborhood and Windows Me/2000/XP My Network Places icons display computers by workgroup name. Different workgroup names actually create different workgroups, and you'd need to access them by browsing via Entire Network. This wastes time.

Problem

Shared resources are not available.

Solution

Make sure that shared resources have been set for any servers on your network (including peer servers on Windows 9x). If you can't share a resource through Windows Explorer on the peer server, ensure that File and Printer Sharing has been installed.

Problem

Network doesn't work after making changes.

Solution

Did you reboot? Any change in the Network icon in Windows 9x/Me Control Panel requires a system reboot!

Did you log in? Any network resources can't be accessed unless you log in when prompted. You can use Start, Shutdown, and Close All Programs and Logon As a New User with Windows 9x/Me to recover quickly from a failure to log on.

Networks in Use

Problem

A user can't access any shared resources (but others can).

Solution

First, have the user log off and log back on. Pressing Cancel or Esc instead of logging in would keep a user off the network.

Next, check cable connections at the server and workstation. Loose terminators or BNC T-connectors can cause trouble for all workstations on a Thinnet cable segment. A loose or disconnected RJ-45 cable affects only the computer (or hub) using it. If a Category 5 UTP cable seems to be connected tightly but the user still can't get on the network, check the cable with a cable tester or replace the cable.

Problem

Wrong access level.

Solution

If you save your passwords in a password cache, entering the read-only password instead of the full-access password limits your access with peer servers. Try unsharing the resource and try to reshare it, or have the user of that peer server set up new full-access and read-only passwords. Alternatively, don't use password caching by unchecking the Save Password box when you log on to a shared

resource. With a client/server network with user lists and rights, check with your network administrator because she will need to change the rights for you.

TCP/IP

Problem

Incorrect settings in Network Properties.

Solution

Get the correct TCP/IP settings from the administrator and enter them; restart the PC.

Problem

Can't keep connection running in Dial-Up Networking.

Solution

You might have the wrong version of PPP running; change the server type in Properties under Dial-Up Networking, not Networks.

Problem

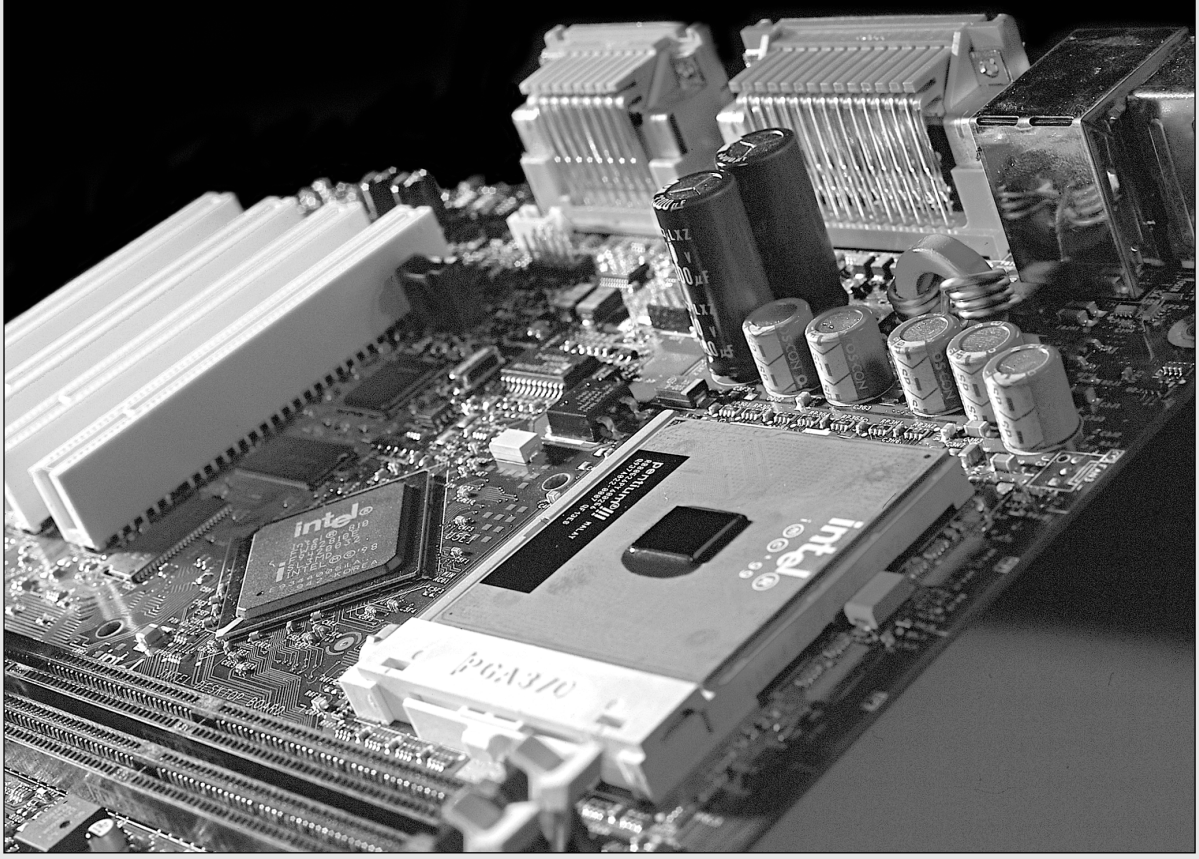
Message about duplicate IP addresses—can't connect to anything.

Solution

Duplicate IP addresses disable both TCP/IP and NetBEUI networking. Internet sharing products such as ICS, third-party sharing programs, and routers are usually configured to assign IP addresses automatically to avoid duplication. If some computers on a network have fixed IP addresses and others have dynamically assigned IP addresses, conflicts could occur. The entire network should use dynamic IP addressing (DHCP) or each computer should be assigned a unique IP address.

Problem

No error message—can't connect to Internet or other computers.



Solution

Check the router, switch, or hub used to connect the computers to each other and the Internet. It needs to be powered, and the data cables must be properly connected between it and each PC (and between the Internet connection and the switch or hub, if applicable).

If your network uses DHCP to dynamically assign IP addresses and the router has lost power or connection, users won't have valid IP addresses. Restart the router, and have all users log off and shut down. When they restart their systems, they should be able to obtain valid IP addresses and connect with each other.

CHAPTER 21

Power Supply and Chassis/Case

Considering the Importance of the Power Supply

The power supply is not only one of the most important parts in a PC, but it is unfortunately also the most overlooked. In the words of a famous comedian, the power supply gets no respect! People spend hours discussing their processor speeds, memory capacity, disk storage capacity and speed, video adapter performance, monitor size, and so forth but rarely even mention or consider their power supply. When a system is put together to meet the lowest possible price point, what component do you think the manufacturer skimps on? Yes, the power supply. To most people, the power supply is a rather nondescript, unglamorous metal box that sits inside their systems, something to which they pay virtually no attention at all. The few who do pay any mind seem concerned only with how many watts of power it is rated to put out (even though no practical way exists to verify those ratings), without regard as to whether the power being produced is clean and stable or whether it is full of noise, spikes, and surges.

I have always placed great emphasis on selecting a power supply for my systems. I consider the power supply the core of the system and am willing to spend more to get a better unit. The power supply function is critical because it supplies electrical power to every other component in the system. In my experience, the power supply is also one of the most failure-prone components in any computer system. I have replaced more power supplies in PCs than any other part. This is especially due to the fact that so many system builders use the cheapest power supplies they can find. A malfunctioning power supply can not only cause other components in the system to malfunction, but also can damage the other components in your computer by delivering an improper or erratic voltage. Because of its importance to proper and reliable system operation, you should understand both the function and limitations of a power supply, as well as its potential problems and their solutions.

This chapter covers the power supply in detail. I focus on the electrical functions of the supply and the mechanical form factors and physical designs that have been used in PC systems in the past, as well as today. Because the physical shape (*form factor*) of the power supply relates to the case, some of this information also relates to the type of chassis or case you have.

Primary Function and Operation

The basic function of the power supply is to convert the type of electrical power available at the wall socket to the type the computer circuitry can use. The power supply in a conventional desktop system is designed to convert either 115-volt (nominal) 60Hz AC (alternating current) or 230v (nominal) 50Hz AC power into +3.3v, +5v, and +12v DC (direct current) power. Some power supplies require you to switch between the two input ranges, whereas others auto-switch.

Positive DC Voltages

Usually, the digital electronic components and circuits in the system (motherboard, adapter cards, and disk drive logic boards) use the +3.3v or +5v power, and the motors (disk drive motors and any fans) use the +12v power. Table 21.1 lists these devices and their power consumptions.

Table 21.1 Power Consumption Ratings for PC Devices

Voltage	Devices Powered
+3.3v	Chipsets, DIMMs, PCI/AGP cards, miscellaneous chips
+5v	Disk drive logic, SIMMs, PCI/AGP cards, ISA cards, voltage regulators, miscellaneous chips
+12v	Motors, voltage regulators (high output)

The power supply must deliver a good, steady supply of DC power so the system can operate properly. Devices that run on voltages other than these must be powered by onboard voltage regulators. For example, RIMMs and DDR dual inline memory modules (DIMMs) require 2.5v, whereas AGP 4x and faster cards require 1.5v—both of which are supplied by simple onboard regulators. Processors also require a wide variety of voltages (as low as 1.3v or less) that are supplied by a sophisticated voltage regulator module (VRM) that is either built in or plugged in to the motherboard as well. You'll commonly find three or more different voltage regulator circuits on a modern motherboard.

Note

When Intel began releasing processors that required a +3.3v power source, power supplies that supplied the additional output voltage were not yet available. As a result, motherboard manufacturers began adding voltage regulators to their boards, which converted +5v current to +3.3v for the processor. When other chips began using 3.3v as well, Intel created the ATX power supply specification, which supplied 3.3v to the motherboard. DIMMs also run on +3.3v as supplied by the power supply. You would think that having 3.3v direct from the power supply would have eliminated the need for onboard voltage regulators, but by that time, processors began running on a wide variety of voltages lower than 3.3v. Motherboard manufacturers then included adaptable regulator circuits called voltage regulator modules to accommodate the widely varying processor voltage requirements. Other regulators are also used to power any other devices on the motherboard that don't use +3.3v, +5v, or +12v.

◀◀ See "CPU Operating Voltages," p. 105.

Negative DC Voltages

If you look at a specification sheet for a typical PC power supply, you can see that the supply generates not only +3.3v, +5v, and +12v, but also –5v and –12v. The positive voltages seemingly power everything in the system (logic and motors), so what are the negative voltages used for? The answer is not much! Some of the power supply designs, such as the small form factor (SFX) design, no longer include the –5v output for that reason. The only reason it has remained in most power supply designs is that –5v is required on the Industry Standard Architecture (ISA) bus for full backward-compatibility.

Although –5v and –12v are supplied to the motherboard via the power supply connectors, the motherboard normally uses only the +3.3v, +5v, and +12v. The –5v is simply routed to the ISA bus on pin B5 so any ISA cards can use it, even though not many do today. However, as an example, the analog data separator circuits found in older floppy controllers do use –5v.

The motherboard logic typically doesn't use –12v either; however, it might be used in some board designs for serial port or LAN circuits.

Note

The load placed on the –12v output by an integrated LAN adapter is very small. For example, the integrated 10/100 Ethernet adapter in the Intel D815EEAL motherboard uses only 10mA of +12v and 10mA of –12v (0.01 amps each) to operate.

Although older serial port circuits used +/–12v outputs, today most run only on +3.3v or +5v.

The main function of the +12v power is to run disk drive motors as well as the higher-output processor voltage regulators in some of the newer boards. Usually, a large amount of +12v current is available from the power supply, especially in those designed for systems with a large number of drive bays (such as in a tower configuration). Besides disk drive motors and newer CPU voltage regulators, the +12v supply is used by any cooling fans in the system—which, of course, should always be

running. A single cooling fan can draw between 100mA and 250mA (0.1–0.25 amps); however, most newer fans use the lower 100mA figure. Note that although most fans in desktop systems run on +12v, portable systems can use fans that run on +5v or even +3.3v.

Most systems with newer motherboard form factors, such as the ATX, micro-ATX, or NLX, include another special signal. This feature, called PS_ON, can be used to turn the power supply (and thus the system) on or off via software. It is sometimes known as the *soft-power feature*. PS_ON is most evident when you use it with an operating system such as Windows that supports the Advanced Power Management (APM) or Advanced Configuration and Power Interface (ACPI) specification. When you select the Shut Down the Computer option from the Start menu, Windows automatically turns off the computer after it completes the OS shutdown sequence. A system without this feature only displays a message that it's safe to shut down the computer.

The Power_Good Signal

In addition to supplying electrical power to run the system, the power supply also ensures that the system does not run unless the power supplied is sufficient to operate the system properly. In other words, the power supply actually prevents the computer from starting up or operating until all the power supply voltages are within the proper ranges.

The power supply completes internal checks and tests before allowing the system to start. If the tests are successful, the power supply sends a special signal to the motherboard, called Power_Good. This signal must be continuously present for the system to run. Therefore, when the AC voltage dips and the power supply can't maintain outputs within regulation tolerance, the Power_Good signal is withdrawn (goes low) and forces the system to reset. The system will not restart until the Power_Good signal returns.

The Power_Good signal (sometimes called Power_OK or PWR_OK) is a +5v (nominal) active high signal (with a variation from +2.4v through +6.0v generally being considered acceptable) that is supplied to the motherboard when the power supply has passed its internal self tests and the output voltages have stabilized. This typically takes place anywhere from 100ms to 500ms (0.1–0.5 seconds) after you turn on the power supply switch. The power supply then sends the Power_Good signal to the motherboard, where the processor timer chip that controls the reset line to the processor receives it.

In the absence of Power_Good, the timer chip holds the reset line on the processor, which prevents the system from running under bad or unstable power conditions. When the timer chip receives the Power_Good signal, it releases the reset and the processor begins executing whatever code is at address FFFF:0000 (usually the ROM BIOS).

If the power supply can't maintain proper outputs (such as when a brownout occurs), the Power_Good signal is withdrawn and the processor is automatically reset. When the power output returns to its proper levels, the power supply regenerates the Power_Good signal and the system again begins operation (as if you had just powered on). By withdrawing Power_Good before the output voltages fall out of regulation, the system never sees the bad power because it is stopped quickly (reset) rather than being allowed to operate using unstable or improper power levels, which can cause memory parity errors and other problems.

Note

You can use the Power_Good feature as a method of implementing a reset switch for the PC. The Power_Good line is wired to the clock generator circuit, which controls the clock and reset lines to the microprocessor. When you ground the Power_Good line with a switch, the timer chip and related circuitry reset the processor. The result is a full hardware reset of the system. Instructions for making and installing a reset switch can be found in the section "Making and Installing a Reset Switch" in the Technical Reference portion of the DVD included with this book.

◀◀ See "Parity and ECC," p. 457.

On pre-ATX systems, the Power_Good connection is made via connector P8-1 (P8 Pin 1) from the power supply to the motherboard. ATX and later systems use pin 8 of the 20-pin connector, which is usually a gray wire.

A well-designed power supply delays the arrival of the Power_Good signal until all the voltages stabilize after you turn on the system. Badly designed power supplies, which are found in many low-cost systems, often do not delay the Power_Good signal properly and enable the processor to start too soon. (The normal Power_Good delay is 0.1–0.5 seconds.) Improper Power_Good timing also causes CMOS memory corruption in some systems.

Note

If you find that a system consistently fails to boot up properly the first time you turn on the switch, but that it subsequently boots up if you press the reset or Ctrl+Alt+Delete warm boot command, you likely have a problem with the Power_Good timing. You should install a new, higher-quality power supply and see whether that solves the problem.

Some cheaper power supplies do not have proper Power_Good circuitry and might just tie any +5v line to that signal. Some motherboards are more sensitive to an improperly designed or improperly functioning Power_Good signal than others. Intermittent startup problems are often the result of improper Power_Good signal timing. A common example is when you replace a motherboard in a system and then find that the system intermittently fails to start properly when you turn on the power. This can be very difficult to diagnose, especially for the inexperienced technician, because the problem appears to be caused by the new motherboard. Although it seems as though the new motherboard is defective, it usually turns out that the power supply is poorly designed. It either can't produce stable enough power to properly operate the new board or has an improperly wired or timed Power_Good signal (which is more likely). In these situations, replacing the supply with a higher-quality unit, in addition to the new motherboard, is the proper solution.

Power Supply Form Factors

The shape and general physical layout of a component is called the *form factor*. Items that share a form factor are generally interchangeable, at least as far as their sizes and fits are concerned. When designing a PC, the engineers can choose to use one of the popular standard power supply unit (PSU) form factors, or they can elect to build their own. Choosing the former means that a virtually inexhaustible supply of inexpensive replacement parts will be available in a variety of quality and power output levels. Going the custom route means additional time and expense for development. In addition, the power supply is unique to the system and available only from the original manufacturer.

If you can't tell already, I am a fan of the industry-standard form factors! Having standards and then following them allows us to upgrade and repair our systems by easily replacing physically (and electrically) interchangeable components. Having interchangeable parts means that we have a better range of choices for replacement items, and the competition makes for better pricing, too.

In the PC market, IBM originally defined the standards and everybody else copied them. This included power supplies. All the popular PC power supply form factors up through 1995 were based on one of three IBM models, including the PC/XT, AT, and PS/2 Model 30. The interesting thing is that these three power supply definitions all had the same motherboard connectors and pinouts; where they differed was mainly in shape, maximum power output, the number of peripheral power connectors, and switch mounting. PC systems using knock-offs of one of those three designs were popular through 1996 and beyond, and some systems still use them today.

Intel gave the power supply a new definition in 1995 with the introduction of the ATX form factor. ATX became popular in 1996 and started a shift away from the previous IBM-based standards. ATX and the related standards that followed have different connectors with additional voltages and signals that allow systems with greater power consumption and additional features that would otherwise not be possible with the AT style supplies.

Technically, the power supply in your PC is described as a *constant voltage half-bridge forward converting switching power supply*, which is defined as follows:

- *Constant voltage* means that the power supply puts out the same voltage to the computer's internal components, no matter what the voltage of AC current running it or the capacity (wattage) of the power supply.
- *Half-bridge forward converting switching* refers to the design and power regulation technique that most suppliers use. This design is commonly referred to as a *switching supply*. Compared to other types of power supplies, this design provides an efficient and inexpensive power source and generates a minimum amount of heat. It also maintains a small size and low price.

Note

Although two power supplies can share the same basic design and form factor, they can differ greatly in quality and efficiency. Later in this chapter, you'll learn about some of the features and specifications to look for when evaluating PC power supplies.

Seven power supply physical form factors have existed that can be called industry standard. Five of these are based on IBM designs, whereas two are based on Intel designs. Of these, only the two Intel-based designs are used in most modern systems; the others are pretty much obsolete.

Note that although the names of the power supply form factors seem to be the same as those of motherboard form factors, the power supply form factor is more closely related to the system chassis (case) than the motherboard. That is because all the form factors use one of only two types of connector designs: either AT or ATX.

For example, all PC/XT, AT, and LPX form factor supplies use the same pair of six-pin connectors to plug into the motherboard and will therefore power any board having the same type of power connections. Plugging into the motherboard is one thing, but for the power supply to physically work in the system, it must fit the case. The bottom line is that it is up to you to ensure that the power supply you purchase not only plugs into your motherboard, but also fits into the chassis or case you plan to use.

Table 21.2 shows these power supply form factors, their connection types, and associated motherboards.

Table 21.2 Power Supply Connector Types and Form Factors

Obsolete PS Form Factors	Originated From	Connector Type	Associated MB Form Factors
PC/XT style	IBM PC, PC-XT (1981/1983)	AT	PC/XT, Baby-AT
AT/Desk style	IBM PC-AT (1984)	AT	Full-size AT, Baby-AT
AT/Tower style	IBM PC-AT (1984)	AT	Full-size AT, Baby-A
Baby-AT style	IBM PC-AT (1984)	AT	Full-size AT, Baby-AT
LPX style*	IBM PS/2 Model 30 (1987)	AT	Baby-AT, Mini-AT, LPX

Table 21.2 Continued

Modern PS Form Factors	Originated From	Connector Type	Associated MB Form Factors
ATX style	Intel ATX, ATX12V (1995/2000)	ATX	ATX, NLX, Micro-ATX
SFX style	Intel SFX (1997)	ATX	Flex-ATX, Micro-ATX

**Note: LPX is also sometimes called Slimline or PS/2.*

Each of these power supply form factors is available in numerous configurations and power output levels. The LPX form factor supply was the standard used on most systems from the late 1980s to mid-1996, when the ATX form factor started to gain in popularity. Since then, ATX has become by far the dominant form factor for power supplies, with the new SFX style being added as an ATX derivative for use in very compact systems that mainly use Flex-ATX-sized boards. The earlier IBM-derived form factors have been largely obsolete for some time now. Any power supply that does not conform to one of these standards is considered *proprietary*. Any systems that use proprietary designs should generally be avoided because replacements are difficult to obtain and upgrades are generally not available.

◀◀ See "Motherboard Form Factors," p. 202.

PC/XT Style

IBM's PC and XT systems (circa 1981 and 1983, respectively) used the same power supply form factor; the only difference was that the XT supply had more than double the power output capability. Because they were identical in external appearance and the type of connectors they used, you easily could install the higher-output XT supply as an upgrade for a PC system; thus, the idea of upgrading the power supply was born. The tremendous popularity of the original PC and XT systems led several manufacturers to begin building systems that mimicked their shapes and layouts. These clones or compatibles, as they have been called, could interchange virtually all components with the IBM systems, including the power supply. Numerous manufacturers then began producing components that followed the form factor of these systems. The PC/XT power supply and connectors are shown in Figure 21.1. This form factor, however, is not used in modern systems today.

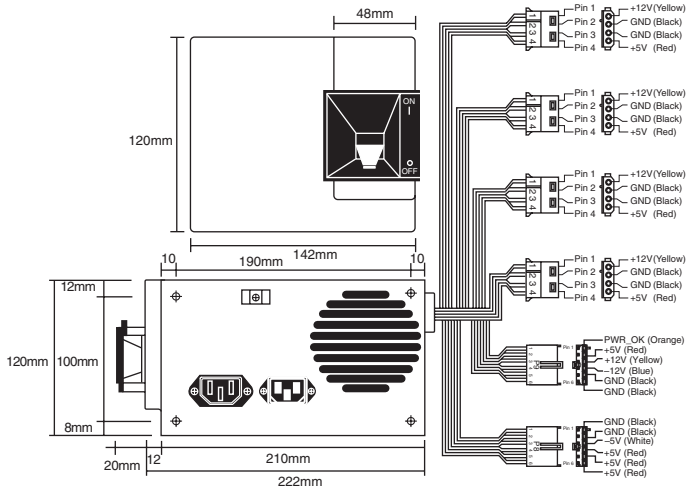


Figure 21.1 PC/XT form factor power supply.

AT/Desk Style

The AT desktop system that IBM introduced in August 1984, had a larger power supply and a form factor different from the original PC/XT. Other manufacturers rapidly cloned this system, which represented the basis for many subsequent IBM-compatible designs. The power supply used in these systems was called the AT/Desktop-style power supply (see Figure 21.2). Hundreds of manufacturers began making motherboards, power supplies, cases, and other components that were physically interchangeable with the original IBM AT. This form factor is no longer used today.

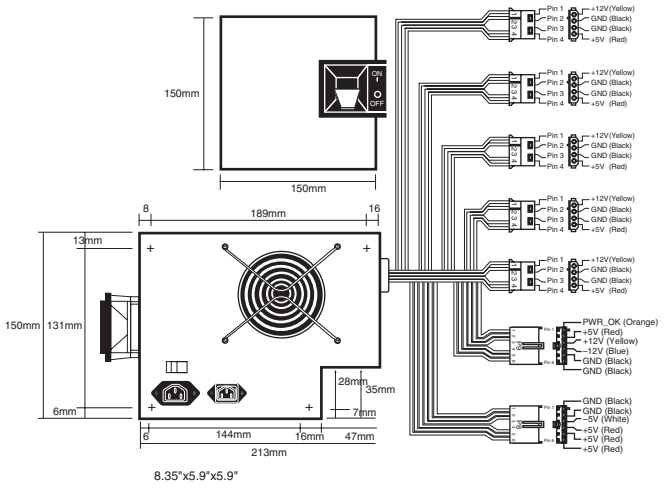

Figure 21.2 AT/Desktop form factor power supply.

AT/Tower Style

The AT/Tower configuration was basically a full-sized, AT-style desktop system running on its side. The tower configuration was not new; in fact, even IBM's original AT had a specially mounted logo that could be rotated when you ran the system on its side in the tower configuration.

The type of power supply used in most of the AT tower systems was identical to that used in a desktop system, except for the location of the power switch. On the original AT/Desktop systems, the power switch was built into the side of the power supply (usually in the form of a large toggle switch). AT/Tower systems instead used an external switch attached to the power supply through a four-wire cable. A full-sized AT power supply with a remote switch is called an AT/Tower form factor power supply and is identical to the AT/Desktop supply in size and dimensions. The only difference is the use of an external switch (see Figure 21.3). This form factor is still used today in large server chassis that run AT form factor motherboards.

Baby-AT Style

Another type of AT-based form factor is the so-called Baby-AT, which is a shortened version of the full-size AT form factor. The power supply in these systems is shortened in one dimension but matches the AT design in all other respects. Baby-AT-style power supplies could fit in place of the larger AT/Desktop-style supply; however, the full-size AT/Tower supply would not fit in the Baby-AT chassis (see Figure 21.4). Because the Baby-AT PSU performed the same functions as the AT-style power supply but was in a smaller package, it became a common form factor until it was overtaken by later designs. This form factor is rarely used today.

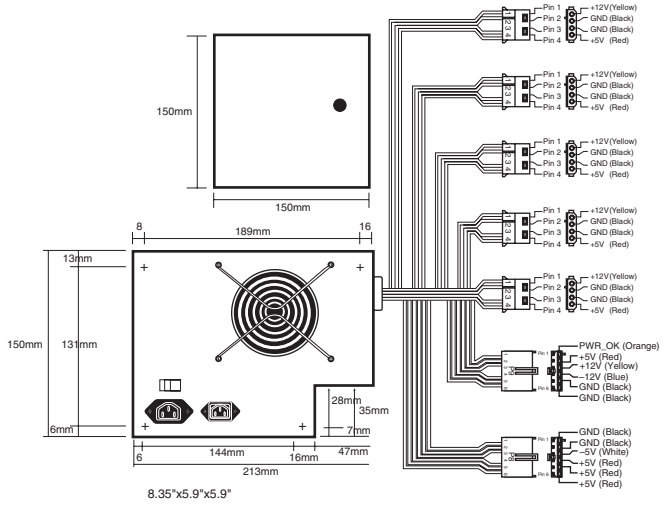

Figure 21.3 AT/Tower form factor power supply.

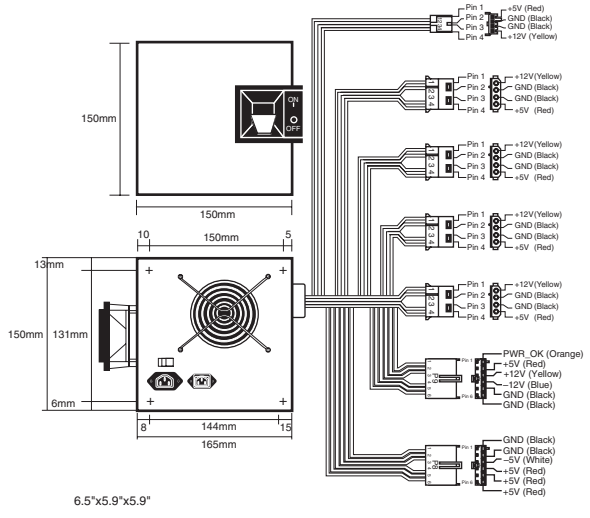

Figure 21.4 Baby-AT form factor power supply.

LPX Style

The next power supply form factor to gain popularity was the LPX style, also called the PS/2 type, Slimline, or slim style (see Figure 21.5). The LPX-style power supply has the exact same motherboard and disk drive connectors as the previous standard power supply form factors; it differs mainly in the shape. LPX systems were designed to have a smaller footprint and a lower height than AT-size systems. These computers used a different motherboard configuration that mounts the expansion bus slots on a "riser" card that plugs into the motherboard. The expansion cards plug into this riser and are mounted sideways in the system, parallel to the motherboard. Because of its smaller case, an LPX

system needs a smaller power supply. The power supply designed for LPX systems is smaller than the Baby-AT style in every dimension and takes up less than half the space of its predecessor.

Note

IBM used the LPX power supply in some of its PS/2 systems in the late 1980s; hence it is sometimes called a PS/2-type supply.

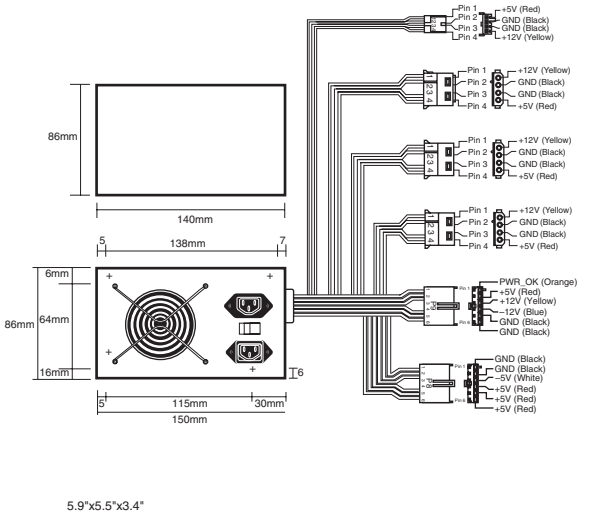

Figure 21.5 LPX form factor power supply.

As with the Baby-AT design in its time, the LPX power supply does the same job as its predecessor but comes in a smaller package. The LPX power supply quickly found its way into many manufacturers' systems and soon became a de facto standard. This style of power supply became the staple of the industry for many years, coming in everything from low-profile systems using actual LPX motherboards to full-size towers using Baby-AT or even full-size AT motherboards. It still is used in some PCs produced today; however, since 1996 the popularity of LPX has been overshadowed by the increasing popularity of the ATX design.

ATX Style

The current standard in the industry is the ATX form factor (see Figure 21.6). The ATX specification, now in version 2.03**,** defines a new motherboard shape from its predecessors, as well as a new case and power supply form factor.

The shape of the ATX power supply is based on the LPX design, but some important differences are worth noting.

One difference is that the ATX specification originally called for the fan to be mounted along the inner side of the supply, where it could draw air in from the rear of the chassis and blow it inside across the motherboard. This kind of airflow runs in the opposite direction as most standard supplies, which exhaust air out the back of the supply through a hole in the case where the fan protrudes. The idea was that the reverse flow design could cool the system more efficiently with only a single fan, eliminating the need for a fan (active) heatsink on the CPU.

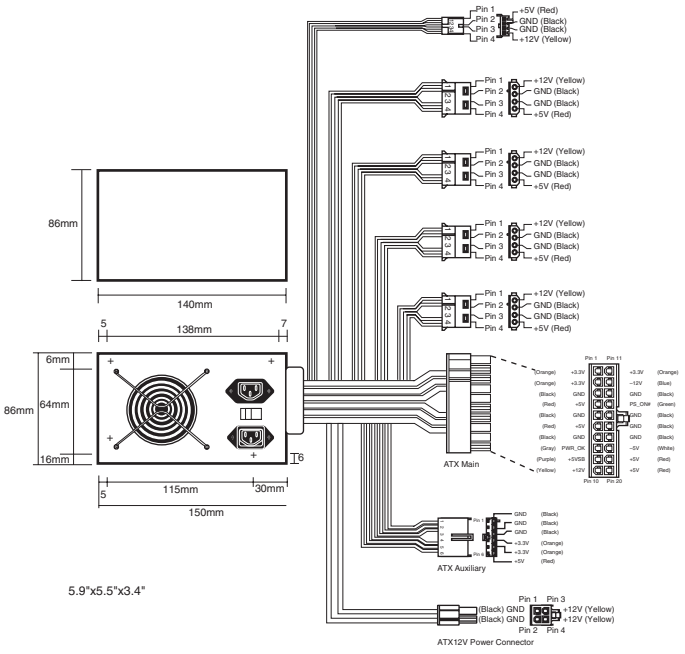

Figure 21.6 ATX form factor power supply with optional Auxiliary and ATX12V connectors.

Another benefit of the reverse-flow cooling is that the system would run cleaner, freer from dust and dirt. The case would be pressurized, so air would be continuously forced out of the cracks in the case—the opposite of what happens with a negative pressure design. For this reason, the reverse-flow cooling design is often referred to as a positive-pressure-ventilation design. On an ATX system with reverse-flow cooling, the air is blown out away from the drive because the only air intake is the single fan vent on the power supply at the rear. For systems that operate in extremely harsh environments, you can add a filter to the fan intake vent to further ensure that all the air entering the system is clean and free of dust.

Although this sounds like a good way to ventilate a system, the positive-pressure design needs to use a more powerful fan to pull the required amount of air through a filter and pressurize the case. Also, if a filter is used, it must be serviced on a periodic basis—depending on operating conditions, it could need changing or cleaning as often as every week. In addition, the heat load from the power supply on a fully loaded system heats the air being ingested, blowing warm air over the CPU and reducing the overall cooling capability.

As CPUs evolved to generate more and more heat, the cooling capability of the system became more critical and the positive-pressure design was simply not up to the task. Therefore, subsequent versions of the ATX specification were rewritten to allow both positive- and negative-pressure designs, but they emphasized the standard negative-pressure system with an exhaust fan on the power supply and an additional high-quality cooling fan blowing cool air right on the CPU as the best solution.

Because a standard negative-pressure system offers the greatest cooling capacity for a given fan's airspeed and flow, virtually all the newer ATX-style power supplies use a negative-pressure design, in which air flows out the back of the power supply.

Intel first released the ATX specification in 1995. In 1996, it became increasingly popular in Pentium and Pentium Pro–based PCs, capturing 18% of the motherboard market within the first year. Since 1996, ATX has become the dominant motherboard form factor, displacing the previously popular Baby-AT. ATX and its derivatives are likely to remain the most popular form factor for several years to come.

The ATX form factor addressed several problems with the previous AT-type and LPX-type supplies. One is that the power supplies used with Baby-AT boards have two connectors that plug into the motherboard. If you insert these connectors backward or out of their normal sequence, you will fry the motherboard! Most responsible system manufacturers "key" the motherboard and power supply connectors so that you can't install them backward or out of sequence. However, most vendors of cheaper systems did not feature this keying on the boards or supplies they used. The ATX form factor includes intelligently designed power plugs for the motherboard to prevent users from plugging in their power supplies incorrectly. The ATX design features up to three motherboard power connectors that are definitively keyed, making plugging them in backward virtually impossible. The new ATX connectors also supply +3.3v, reducing the need for voltage regulators on the motherboard to power the chipset, DIMMs, and other +3.3v circuits.

Besides the new +3.3v outputs, ATX power supplies furnish another set of outputs that is not typically seen on standard power supplies. The set consists of the Power_On (PS_ON) and 5V_Standby (5VSB) outputs mentioned earlier, known collectively as *Soft Power*. This enables features to be implemented, such as Wake on Ring or Wake on LAN, in which a signal from a modem or network adapter can actually cause a PC to wake up and power on. Many such systems also have the option of setting a wake-up time, at which the PC can automatically turn itself on to perform scheduled tasks. These signals also can enable the optional use of the keyboard to power the system on—just like Apple systems. Users can enable these features because the +5v Standby power is always active, giving the motherboard a limited source of power even when off. Check your BIOS Setup for control over these features.

NLX Style

The NLX specification—one that Intel also developed—defines a low-profile case and motherboard design with many of the same attributes as the ATX. In fact, for interchangeability, NLX systems were designed to use ATX power supplies, even though the case and motherboard dimensions are different.

As in previous LPX systems, the NLX motherboard uses a riser board for the expansion bus slots. Where NLX differs is that it is a true (and not proprietary) standard. See Chapter 4, "Motherboards and Buses," for more information on the NLX form factor.

For the purposes of this discussion, NLX systems use ATX power supplies. The only real difference is that the supply plugs into the riser card and not the motherboard, enabling NLX motherboards to be more quickly and easily removed from their chassis for service.

SFX Style

Intel released the smaller Micro-ATX motherboard form factor in December 1997, and at the same time also released a new smaller SFX power supply design to go with it (see Figure 21.7). Even so, most Micro-ATX chassis used the standard ATX power supply instead. Then in March 1999, Intel released the Flex-ATX addendum to the Micro-ATX specification, which was a very small board designed for low-end PCs or PC-based appliances. Now, the SFX supply has found use in many new compact system designs.

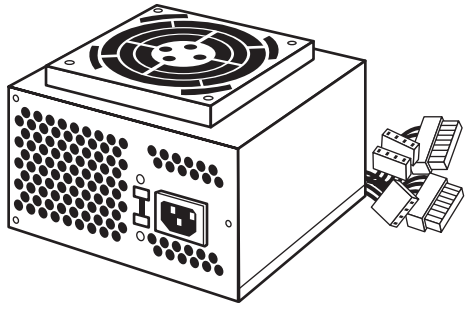

Figure 21.7 SFX-style power supply (with 90mm top-mounted cooling fan).

The SFX power supply is specifically designed for use in small systems containing a limited amount of hardware and limited upgradability. Most SFX supplies can provide 90 watts of continuous power (135 watts at its peak) in four voltages (+5v, +12v, –12v, and +3.3v). This amount of power has proven to be sufficient for a small system with a processor, an AGP interface, up to four expansion slots, and three peripheral devices—such as hard drives and CD-ROMs.

Although Intel designed the SFX power supply specification with the Micro-ATX and Flex-ATX motherboard form factors in mind, SFX is a wholly separate standard that is compliant with other motherboards as well. SFX power supplies use the same 20-pin connector defined in the ATX standard and include both the Power_On and 5V_Standby outputs. Whether you will use an ATX or SFX power supply in a given system depends more on the case or chassis than the motherboard. Each has the same basic electrical connectors; the main difference is which type of power supply the case is physically designed to accept.

One limiting factor of the SFX design is that it lacks the –5v and so shouldn't be used with motherboards that have ISA slots (most Micro-ATX and Flex-ATX boards do NOT have ISA slots). SFX power supplies also don't have the Auxiliary (3.3v and 5v) or ATX12V power connectors and therefore shouldn't be used with full-size ATX boards that require those connections.

On a standard model SFX power supply, a 60mm diameter cooling fan is located on the surface of the housing, facing the inside of the computer's case (see Figure 21.8). The fan draws the air into the power supply housing from the system cavity and expels it through a port at the rear of the system. Internalizing the fan in this way reduces system noise and results in a standard negative-pressure design. In many cases, additional fans might be needed in the system to cool the processor.

For systems that require more cooling capability, a version that allows for a larger, 90mm top-mounted cooling fan also is available. The larger fan provides more cooling capability and airflow for systems that need it (see Figure 21.9).

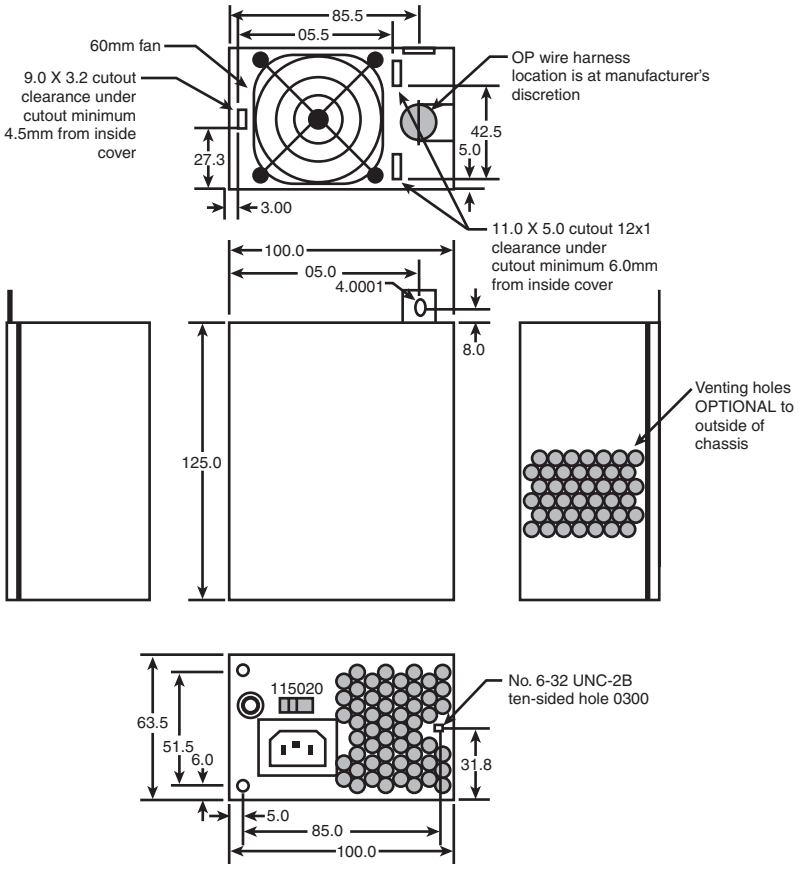

Figure 21.8 SFX form factor power supply dimensions with a standard internal 60mm fan.

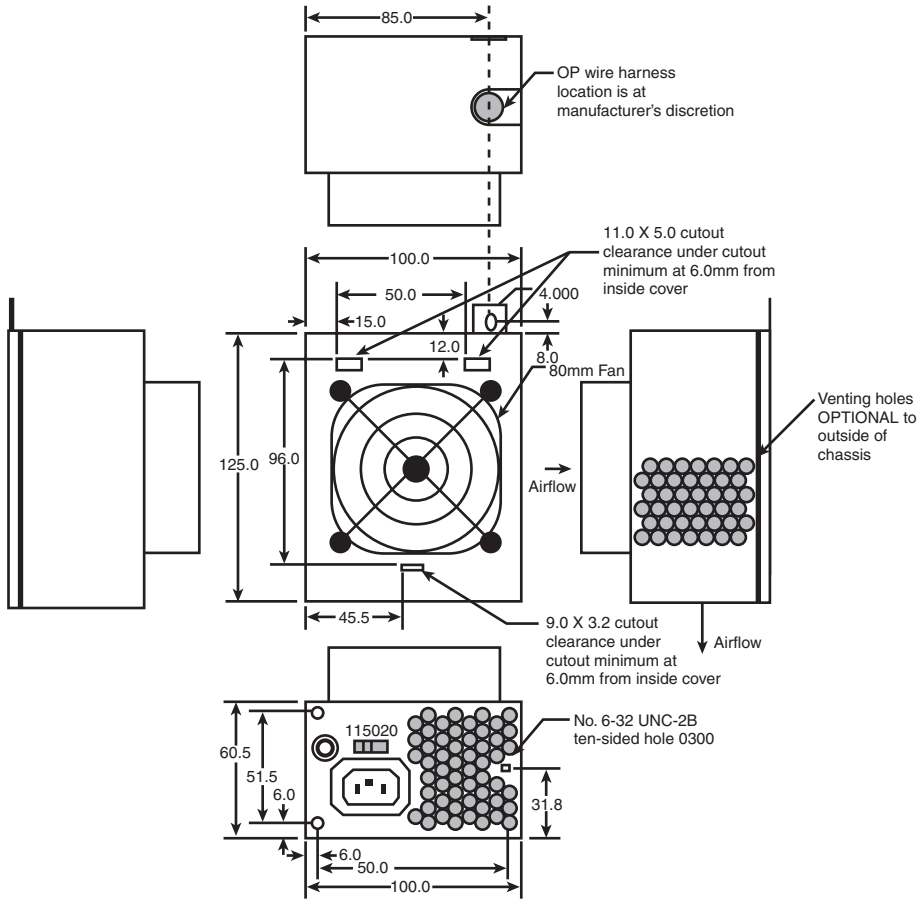

Figure 21.9 SFX form factor power supply dimensions with an internal 90mm top-mounted fan.

Motherboard Power Connectors

Every PC power supply has special connectors that attach to the motherboard, giving power to the system processor, memory, and all slotted add-on boards (ISA, PCI, and AGP). Attaching these connectors improperly can have a devastating effect on your PC, including burning up both your power supply and motherboard. The following sections detail the motherboard power connectors used by various power supplies.

AT Power Supply Connectors

Industry standard PC, XT, AT, Baby-AT, and LPX motherboards all use the same type of main power supply connectors. AT power supplies feature two main power connectors (P8 and P9), each with six pins that attach the power supply to the motherboard. These are rated at 5 amps per pin, at up to 250v. These two connectors are shown in Figure 21.10.

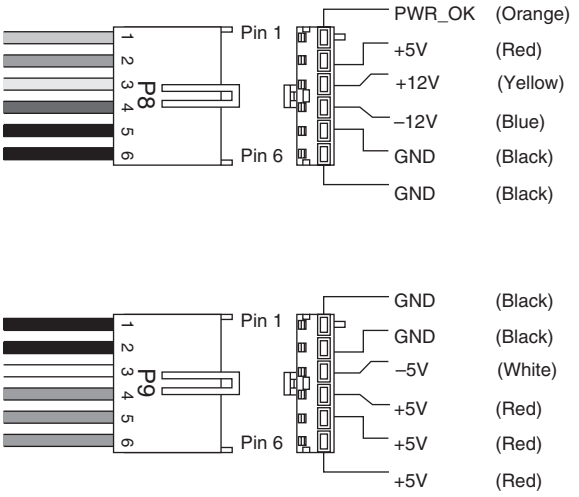

Figure 21.10 AT/LPX main P8/P9 (sometimes also called P1/P2) power connectors.

All standard PC power supplies that use the P8 and P9 connectors have them installed end to end so that the two black wires (ground connections) on both power cables are next to each other. Note the designations "P8" and "P9" are not fully standardized, although most use those designations because that is what IBM stamped on the originals. Some power supplies have them labeled as P1/P2 instead. Because these connectors usually have a clasp that prevents them from being inserted backward on the motherboard's pins, the major concern is getting the two connectors in the correct orientation side by side and also not missing a pin offset on either side. Following the black-to-black rule keeps you safe. You must take care, however, to ensure that no remaining unconnected motherboard pins exist between or on either side of the two connectors after you install them. A properly installed connector connects to and covers every motherboard power pin. If any power pins are showing on either side of or between the connectors, the entire connector assembly is installed incorrectly, which can result in catastrophic failure for the motherboard and everything plugged into it at the time of power-up. Figure 21.11 shows the P8 and P9 connectors (sometimes also called P1/P2) in their proper orientation when connecting.

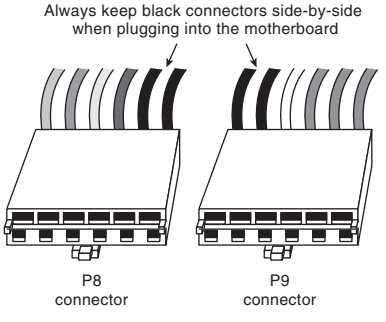

Figure 21.11 The P8/P9 power connectors (sometimes also called P1/P2) that connect an AT/LPX power supply to the motherboard.

Table 21.3 shows typical AT and LPX power supply connections.

Table 21.3 AT/LPX Power Supply Connectors

Connector	Pin	Signal	Color[2]	Connector	Pin	Signal	Color[2]
P8 (or P1)	1	Power_Good (+5v)	Orange	P9 (or P2)	1	Ground	Black
	2	+5v[1]	Red		2	Ground	Black
	3	+12v	Yellow		3	–5v	White
	4	–12v	Blue		4	+5v	Red
	5	Ground	Black		5	+5v	Red
	6	Ground	Black		6	+5v	Red

1. First-generation PC/XT motherboards and power supplies did not require this voltage, so the pin might be missing from the motherboard and terminal and the wire might be missing from the connector (P8 pin 2).

2. I have seen some supplies where the manufacturer did not follow industry-standard wire color-codes even though the signals were correct.

**Older PC/XT motherboards and power supplies did not use this output (P8 pin 2).*

Color codes can vary from manufacturer to manufacturer; the ones shown here are typical.

Tip

Although older PC/XT power supplies do not have any connection at connector P8 pin 2, you still can use them on AT-type motherboards, or vice versa. The presence or absence of the +5v on that pin has little or no effect on system operation because the remaining +5v wires usually can carry the load.

Note that all the AT- and LPX-type power supplies use the same connectors and pin configurations.

ATX Main Power Connector

The industry-standard ATX power supply–to–motherboard main connector is the Molex Mini-Fit, Jr. connector number 39-29-9202 (or equivalent), which is more commonly known as the 20-pin ATX-style connector (see Figure 21.12). Molex rates each pin to handle 6 amps of current (at up to 600v). First used in the ATX form factor power supply, it also is used in the SFX form factor or any other ATX-based variations. This is a 20-pin keyed connector with pins configured as shown in Table 21.4. The colors for the wires listed are those the ATX standard recommends; however, to enable them to vary from manufacturer to manufacturer, they are not required for compliance to the specification. I like to show these connector pinouts in a wire side view, which shows how the pins are arranged looking at the back of the connector (from the wire and not terminal side). This is because it shows how they would be oriented if you were back-probing the connector with the connector plugged in.

Figure 21.13 shows a view of the connector as if you were looking at it facing the terminal side.

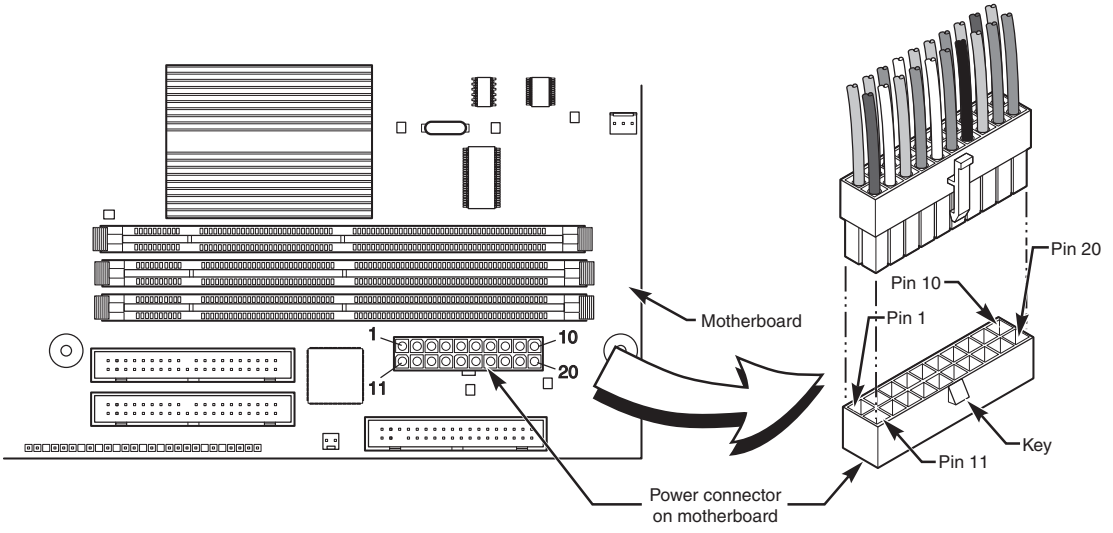

Figure 21.12 ATX-style 20-pin motherboard main power connector, perspective view.

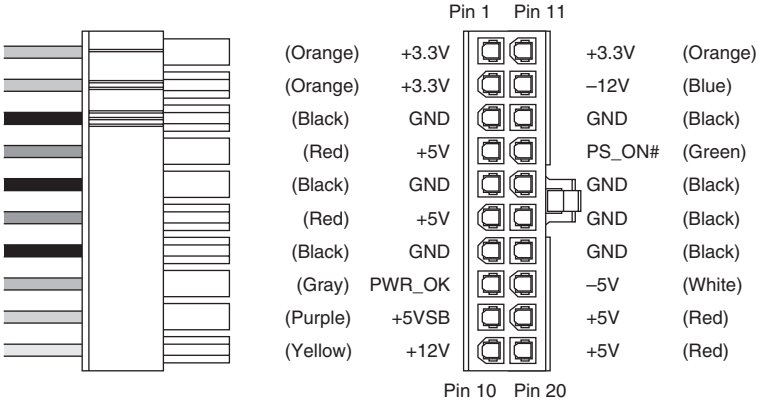

Figure 21.13 ATX/NLX 20-pin main power connector, terminal side view.

Table 21.4 ATX Main Power Supply Connector Pinout (Wire Side View)

Color	Signal	Pin	Pin	Signal	Color
Orange[1]	+3.3v	11	1	+3.3v	Orange
Blue	–12v	12	2	+3.3v	Orange
Black	GND	13	3	GND	Black
Green	PS_On	14	4	+5v	Red
Black	GND	15	5	GND	Black
Black	GND	16	6	+5v	Red

Table 21.4 Continued

Color	Signal	Pin	Pin	Signal	Color
Black	GND	17	7	GND	Black
White	–5v[2]	18	8	Power_Good	Gray
Red	+5v	19	9	+5VSB (Standby)	Purple
Red	+5v	20	10	+12v	Yellow

1. Might have a second orange or brown wire, used for +3.3v sense feedback—used by the power supply to monitor 3.3v regulation.

2. Also might be N/C (no connection) on some later model supplies or motherboards. Supplies with no connection at pin 18 should be used only with motherboards that do not incorporate ISA Bus slots.

Note

The ATX supply features several voltages and signals not seen before, such as the +3.3v, PS_On, and +5V_Standby. Therefore, adapting a standard LPX form factor supply to make it work properly in an ATX system is impossible—even though the shapes of the power supplies themselves are virtually identical.

However, because ATX is a superset of the older LPX power supply standard, you can use a connector adapter to allow an ATX power supply to connect to an older Baby-AT-style motherboard. PC Power and Cooling (see the Vendor List on the DVD) sells this type of adapter.

ATX Auxiliary Power Connector

As motherboards and processors evolved, the need for power became greater. In particular, chipsets and DIMMs were designed to run on 3.3v, increasing the current demand at that voltage. In addition, most boards included CPU voltage regulators that were designed to convert +5v power into the unique voltage levels required by the processors the board supported. Eventually, the high current demands on the +3.3v and +5v outputs were proving too much for the design of the connectors and terminals. Each of the terminals in the main power connector are rated for 6 amps (A), which allows for a maximum draw of 18A of +3.3v power and 24A of +5v power. These maximums match the ratings of an approximately 250-watt-rated power supply. Because motherboards with high-speed processors and multiple cards installed could draw more power than that and power supply manufacturers were building supplies with 300-watt and higher ratings, melted connectors were becoming more and more common. The terminals in the main connector would overheat under such a load.

To allow for additional power from the supply to the motherboard, Intel modified the ATX specification to add a second auxiliary power connector for high power draw ATX motherboards and 250-watt or higher rated supplies. The criteria was such that if the motherboard could draw more than 18A of +3.3v power, and/or more than 24A of +5v power, then the auxiliary connector would be required to carry the additional load. These higher levels of power are needed in systems using 250 to 300 watt or greater supplies.

The ATX Auxiliary Connector is a 6-pin Molex-type connector, similar to one of the motherboard power connectors used on AT/LPX supplies. The terminals in this type of connector are rated for 5 amps per pin at up to 250 volts. The connector is normally keyed to prevent a misaligned connection.

As motherboards and processors evolved, the need for power became greater. In particular, chipsets and DIMMs were designed to run on 3.3v, increasing the current demand at that voltage. In addition, most boards included CPU voltage regulators designed to convert +5v power into the unique voltage levels required by the processors the board supported. Eventually, the high current demands on the

+3.3v and +5v outputs proved too much for the number and gauge of the wires used. Melted connectors became more and more common as these wires overheated under these loads.

Finally, Intel modified the ATX specification to add a second power connector for ATX motherboards and supplies. The criteria was that if the motherboard needed more than 18A of +3.3v power or more than 24A of +5v power, an auxiliary connector would be defined to carry the additional load. These higher levels of power are normally necessary in systems using 250-watt to 300-watt or greater supplies.

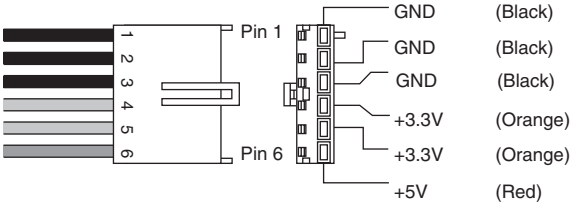

Figure 21.14 ATX auxiliary power connector.

The pinouts of the auxiliary connector are shown in Table 21.5.

Table 21.5 ATX Auxiliary Power Connector Pinout

Pin	Signal	Color	Pin	Signal	Color
1	Gnd	Black	4	+3.3v	Orange
2	Gnd	Black	5	+3.3v	Orange
3	Gnd	Black	6	+5v	Red

If your motherboard does not feature a mate for the auxiliary connector then it probably wasn't designed to consume a large amount of power. In that case, the auxiliary connector from the power supply (if present) can be left unconnected. If your power supply is rated at 250 watts or higher, you should ensure that it has the Auxiliary Connector. Consequently, if your motherboard is capable of drawing more than 18A of +3.3v power or more than 24A of +5v power, you should also ensure that your motherboard has the mating auxiliary power connector. Using the Auxiliary Connector eases the load on the main power connector and prevents melted contacts.

ATX12V Connector

Power for the processor comes from a device called the voltage regulator module (VRM), which is built into most modern motherboards. This device senses the CPU voltage requirements (usually via sense pins on the processor) and calibrates itself to provide the proper voltage to run the CPU. The design of a VRM enables it to run on either 5v or 12v for input power. Most have used 5v over the years, but many are now converting to 12v because of the lower current requirements at that voltage. In addition, other devices might have already loaded the 5v, whereas, typically, only drive motors use the 12v. Whether the VRM on your board uses 5v or 12v depends on the particular motherboard or regulator design. Many modern voltage regulator ICs are designed to run on anything from a 4v to a 36v input, so it is up to the motherboard designer as to how they will be configured.

For example, I studied a system using an FIC (First International Computer) SD-11 motherboard, which used a Semtech SC1144ABCSW voltage regulator. This board design uses the +5v to convert to

the lower voltage the CPU needs. Most motherboards use voltage regulator circuits controlled by chips from Semtech (`http://www.semtech.com`) or Linear Technology (`http://www.linear.com`). You can visit their sites for more data on these chips.

That motherboard accepts an Athlon 1GHz Cartridge version (Model 2), which according to AMD has a maximum power draw of 65W and a nominal voltage requirement of 1.8v. 65W at 1.8v would equate to 36.1A of current at that voltage (volts×amps = watts). If the voltage regulator used +5v as a feed, 65W would equate to only 13A at +5v. That would assume 100% efficiency in the regulator, which is impossible. Therefore, assuming 75% efficiency (it might be better, but I like to think conservatively), there would be about 17A actual draw on the +5v due to the regulator and processor combined.

When you consider that other circuits on the motherboard also use +5v power—plus ISA or PCI cards are drawing that power as well—you can see how easy it is to overload the +5v lines from the supply to the motherboard.

Although most motherboard VRM designs up through the Pentium III and Athlon/Duron use 5v-based regulators, a transition is underway to use 12v-powered regulators. This is because the higher voltage will significantly reduce the current draw. As an example, using the same 65W AMD Athlon 1GHz CPU, you end up with the levels of draw at the various voltages shown in Table 21.6.

Table 21.6 Levels of Draw at Various Voltages

Watts	Volts	Amps	Amps at 75% Regulator Efficiency
65	1.8	36.1	—
65	3.3	19.7	26.3
65	5.0	13.0	17.3
65	12.0	5.4	7.2

As you can see, using 12v to power the chip results in only 5.4A of draw, or 7.2A assuming 75% efficiency on the part of the regulator.

So, modifying the motherboard VRM circuit to use the +12v power feed would seem simple. Unfortunately, the standard ATX 2.03 power supply design has only a single +12v lead in the main power connector. The auxiliary connector has no +12v leads at all, so that is no help. Pulling up to 8A more through a single 18ga. wire supplying +12v power to the motherboard is a recipe for a melted connector because the contacts in the main ATX connector are rated for only 6A.

To augment the supply of +12v power to the motherboard, Intel created a new ATX12V power supply specification. This adds a third power connector, called the ATX12V connector, specifically to supply additional +12v power to the board. This connector has two +12v power pins, each rated for 8 amps total, allowing for up to 16A of additional 12v current to the motherboard. This connector is shown in Figure 21.15.

The pinout of the +12v power connector is shown in Table 21.7.

Table 21.7 ATX +12v Power Connector Pinout (Wire Side View)

Color	Signal	Pin	Pin	Signal	Color
Yellow	+12v	3	1	Gnd	Black
Yellow	+12v	4	2	Gnd	Black

Figure 21.15 An ATX12V power connector.

If you are replacing your motherboard with a new one that requires the ATX12V connection for the CPU voltage regulator, and yet your existing power supply doesn't have that connector, an easy solution is available. Merely convert one of the peripheral power connectors to an ATX12V type. PC Power and Cooling has released just such an adapter that can instantly make any standard ATX power supply into one with an ATX12V connector. This connector works because the issue is not whether the power supply can generate the necessary 12v—that has always been available via the peripheral connectors. The ATX12V adapter shown in Figure 21.16 solves the connector problem quite nicely.

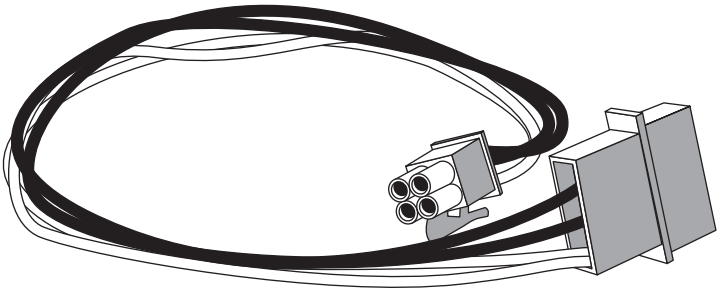

Figure 21.16 ATX12V adapter from PC Power and Cooling.

ATX Optional Connector

The ATX specification also defines an optional six-pin connector. This connector has two rows of three pins each to provide the signals and voltages. The intention was for the computer to use these signals to monitor and control the cooling fan, monitor the +3.3v power to the motherboard, and provide power and grounding to IEEE-1394 (FireWire) devices.

This connector has gone through several revisions in pinout since first being published, and as of yet no motherboards or power supplies on the market (that I am aware of) actually support it. In fact, the latest *ATX/ATX12V Power Supply Design Guide 1.1* published by Intel states, "Details of the 2x3 'Optional Power Connector' mentioned in the ATX 2.03 Specification are omitted from this design guide until such time as the signals on that connector are more rigidly defined." I will include the specifications for this connector in future versions of the book when and if a standard for this connector is defined.

Dell Proprietary (Nonstandard) ATX Design

If you currently own a desktop system made between 1996 and 2000 from Dell, you will definitely want to pay attention to this section. A potential booby trap is waiting to nail the unsuspecting Dell system owner who decides to upgrade either the motherboard or power supply in his system. This hidden trap can cause the destruction of the motherboard, power supply, or both! OK, now that I have your attention, read on….

As those of you who have attended my seminars or read previous editions of this book will know, I have long been a promoter of industry-standard PCs and components and wouldn't think of purchasing a desktop PC that didn't have what I consider an industry-standard form factor motherboard, power supply, and chassis (ATX, for example). I've been down the proprietary road before with systems from Packard Bell, Compaq, IBM, and other companies that used custom, unique, or proprietary components. For example, during a momentary lapse of reason in the early '90s, I purchased a Packard Bell system. I quickly outgrew the capabilities of the system, so I thought I'd upgrade it with a new motherboard and a faster processor. It was then that I discovered, to my horror, that LPX systems were not an interchangeable standard. Because of riser card differences, virtually no interchangeability of motherboards, riser cards, chassis, and power supplies existed. I had what I now refer to as a "disposable PC"—the kind you can't upgrade and have to throw away instead. Suddenly, the money I thought I had saved when initially purchasing the system paled in comparison to what I'd now have to spend to completely replace it. Lesson learned.

After several upgrade and repair experiences like that, I decided never again would I be trapped by systems using proprietary or nonstandard components. By purchasing only systems built with industry-standard parts, I could easily and inexpensively upgrade, maintain, or repair the systems for many years into the future. I have been preaching the gospel of industry-standard components in my seminars and in this book ever since.

Of course, building your own system from scratch is one way to avoid proprietary components, but often that route is more costly in both time and money than purchasing a prebuilt system. And what systems should I recommend for people who want an inexpensive prebuilt system but one that uses industry-standard parts so it can be inexpensively upgraded and repaired later? Although many system vendors and assemblers exist, I've settled on companies such as Gateway, MicronPC, and Dell. In fact, those are really the three largest system vendors that deal direct, and they mostly sell systems that use industry-standard ATX form factor components in all their main desktop system product lines. Or so I thought.

It seems that when Dell converted to the ATX motherboard form factor in mid-1996, it unfortunately defected from the newly released standard and began using specially modified Intel-supplied ATX motherboards with custom-wired power connectors. Inevitably, it also had custom power supplies made that duplicated the nonstandard pinout of the motherboard power connectors.

An even bigger crime than simply using nonstandard power connectors is that only the pinout is nonstandard; the connectors look like and are keyed the same as is dictated by true ATX. Therefore, nothing prevents you from plugging the Dell nonstandard power supply into a new industry-standard ATX motherboard you installed in your Dell case as an upgrade, or even plugging a new upgraded industry-standard ATX power supply into your existing Dell motherboard. But mixing either a new ATX board with the Dell supply or a new ATX supply with the existing Dell board is a recipe for silicon toast. How do you like your fried chips: medium or well-done?

Frankly, I'm amazed I haven't heard more about this because Dell has climbed to the lead in worldwide PC sales. In any case, I figure by getting this information out I can save thousands of innocent motherboards and power supplies from instant death upon installation.

If you've already fallen victim to this nasty circumstance, believe me, I feel your pain. I discovered this the hard way as well—by frying parts. At first, I thought the upgraded power supply I installed in one of my Dell systems was bad, especially considering the dramatic way it smoked when I turned on the system: I actually saw fire through the vents! Good thing I decided to check the color codes on the connectors and verify the pinout on another Dell system by using a voltmeter before I installed and fried a second supply. I was lucky in that the smoked supply didn't take the motherboard with it; I can only surmise that the supply fried so quickly it sacrificed itself and saved the motherboard. You might not be so lucky, and in most cases I'd expect you'd fry the board and supply together.

Call me a fool, but I didn't think I'd have to check the color-coding or get out my voltmeter to verify the Dell "pseudo-ATX" power connector pinouts before I installed a new ATX supply or motherboard. You'll also find that motherboard and power supply manufacturers don't like to replace these items under warranty when they are fried in this manner due to nonstandard connector wiring.

Dell's official explanation for its lack of conformance to the ATX standard was, "In the mid-90s the industry moved to a higher use of 3.3v motherboard components. Dell engineers designed a connector that supported the increased use of 3.3v current which differed from the industry proposed designs that we deemed less than robust." Unfortunately, this explanation doesn't hold much water because the standard ATX connector incorporated three 3.3v pins, allowing for up to 18A of current and the addition of the Auxiliary Connector added two more pins with 10A of additional current. Dell's pseudo-ATX design had only three 3.3v pins in the Auxiliary Connector, which could supply only up to 15A to the board. You can see that even the main ATX Connector alone had more 3.3v current than Dell's design using two connectors!

Because its technical explanation fails to address the issue, the only other reason I can imagine it did this is to lock people into purchasing replacement motherboards or power supplies from Dell. What makes this worse is that Dell uses virtually all Intel-manufactured boards in its systems. One system I have uses an Intel D815EEA motherboard, which is the same board used by many of the other major system builders, including Gateway and Micron. It's the same, except for the power connectors, that is. The difference is that Dell has Intel custom make the boards for Dell with the nonstandard connectors. Everybody else gets virtually the same Intel boards, but with industry-standard connectors.

Tables 21.8 and 21.9 show the nonstandard Dell main and auxiliary power supply connections. This nonstandard wiring is used on Dell's pseudo-ATX systems.

Table 21.8 Dell Proprietary (Nonstandard) ATX Main Power Connector Pinout (Wire Side View)

Color	Signal	Pin	Pin	Signal	Color
Gray	PS_On	11	1	+5v	Red

Table 21.8 Continued

Color	Signal	Pin	Pin	Signal	Color
Red	+5v	18	8	–12v	Blue
KEY (blank)	—	19	9	Gnd	Black
Red	+5v	20	10	Gnd	Black

Table 21.9 Dell Proprietary (Nonstandard) ATX Auxiliary Power Connector Pinout

Pin	Signal	Color	Pin	Signal	Color
1	Gnd	Black	4	+3.3	Blue/White
2	Gnd	Black	5	+3.3	Blue/White
3	Gnd	Black	6	+3.3	Blue/White

At first I thought that if all Dell did was switch some of the terminals around, I could use a terminal pick to remove the terminals from the connectors (with the wires attached) and merely reinsert them into the proper connector positions, enabling me to use the Dell power supply with an upgraded ATX motherboard in the future. Unfortunately, if you study the Dell main and auxiliary connector pinouts I've listed here and compare them to the industry-standard ATX pinouts listed earlier, you'll see that not only are the voltage and signal positions changed, but the number of terminals carrying specific voltages and grounds has changed as well. You could modify a Dell supply to work with a standard ATX board or modify a standard ATX supply to work with a Dell board, but you'd have to do some cutting and splicing in addition to swapping some terminals around. Usually, it isn't worth the time and effort.

If you do decide to upgrade the motherboard in any Dell system purchased between 1996 and 2000, a simple solution is available—just be sure you replace both the motherboard AND power supply with industry-standard ATX components at the same time. That way nothing gets fried, and you'll be back to having a true industry-standard ATX system. If you want to replace just the Dell motherboard, you're out of luck unless you get your replacement board from Dell. On the other hand, if you want to replace just the power supply, you do have one alternative. PC Power and Cooling now makes a version of its high-performance 300W ATX power supply with the modified Dell wiring for about $100. The internals are identical to its industry-standard, high-performance 300W ATX supply (which it sells for about 30% less)—only the number and arrangement of wires has changed.

Fortunately, starting in 2000 Dell switched to using industry-standard ATX power connections in its Dimension 4300, 4400, 8200, and newer systems. That means barring any other unforeseen glitches, these systems should be more easily upgradable by just replacing either the power supply or the motherboard alone. I, for one, am glad to see Dell moving back toward industry standardization because its systems are now more appealing to purchase as a starting point for a system that will be user upgradable and repairable in the future.

Power Switch Connectors

Three main types of power switches are used on PCs. They can be described as follows:

- Integral Power Supply AC switch
- Front Panel Power Supply AC switch
- Front Panel Motherboard Controlled switch

The earliest systems had power switches integrated or built directly into the power supply, which turned the main AC power to the system on and off. This was a simple design, but because the power supply was mounted to the rear or side of the system, it required reaching around to the back to actuate the switch. Also, switching the AC power directly meant the system couldn't be remotely started without special hardware.

Starting in the late '80s, systems began using remote front panel switches. These were essentially the same power supply design as the first type. The only difference was that the AC switch was now mounted remotely (usually on the front panel of the chassis), rather than integrated in the power supply unit. The switch was connected to the power supply via a four-wire cable, and the ends of the cable were fitted with spade connector lugs, which plugged onto the spade connectors on the power switch. The cable from the power supply to the switch in the case contained four color-coded wires. In addition, a fifth wire supplying a ground connection to the case was sometimes included. The switch was usually included with the power supply and heavily shrink-wrapped or insulated where the connector lugs attached to prevent electric shock.

This solved the ergonomic problem of reaching the switch, but it still didn't enable remote or automated system power-up without special hardware. Plus, you now had a 120v AC switch mounted in the chassis, with wires carrying dangerous voltage through the system. Some of these wires are hot anytime the system is plugged in (all are hot with the system turned on), creating a dangerous environment for the average person when messing around inside the system.

Caution

At least two of the remote power switch leads to a remote mounted AC power switch in an AT/LPX supply are energized with 115v AC current at all times. You could be electrocuted if you touch the ends of these wires with the power supply plugged in, even if the unit is turned off! For this reason, always make sure the power supply is unplugged before connecting or disconnecting the remote power switch or touching any of the wires connected to it.

The four or five wires are usually color-coded as follows:

- *Brown and blue.* These wires are the live and neutral feed wires from the 110v power cord to the power supply. These are always hot when the power supply is plugged in.
- *Black and white.* These wires carry the AC feed from the switch back to the power supply. These leads should be hot only when the power supply is plugged in and the switch is turned on.
- *Green or green with a yellow stripe.* This is the ground lead. It should be connected to the PC case and should help ground the power supply to the case.

On the switch, the tabs for the leads are usually color-coded; if not, you'll find that most switches have two parallel tabs and two angled tabs. If no color-coding is on the switch, plug the blue and brown wires onto the tabs that are parallel to each other and the black and white wires to the tabs that are angled away from each other. If none of the tabs are angled, simply make sure the blue and brown wires are plugged into the most closely spaced tabs on one side of the switch and the black and white wires on the most closely spaced tabs on the other side (see Figure 21.17).

Caution

Although these wire color-codings and parallel/angled tabs are used on most power supplies, they are not necessarily 100% universal. I have encountered power supplies that do not use the same coloring or tab placement scheme described here. One thing is sure: Two of the wires will be hot with AC wall current anytime the power supply is plugged in. No matter what, always disconnect the power supply from the wall socket before handling any of these wires. Be sure

to insulate the connections with electrical tape or heat shrink tubing so you won't be able to touch the wires when working inside the case in the future.

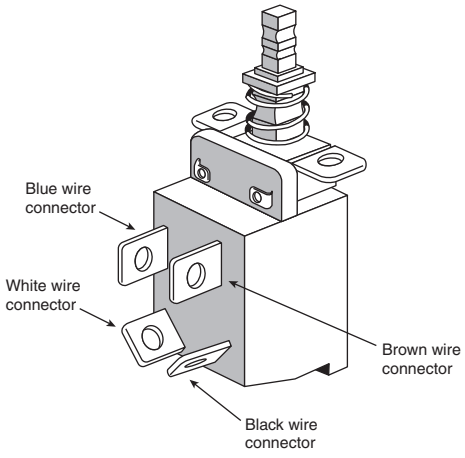

Figure 21.17 Power supply remote push button switch connections.

As long as the blue and brown wires are on the one set of tabs and the black and white leads are on the other, the switch and supply will work properly. If you incorrectly mix the leads, you will likely blow the circuit breaker for the wall socket because mixing them can create a direct short circuit.

All ATX and subsequent power supplies that employ the 20-pin motherboard connector use the PS_ON signal to power up the system. As a result, the remote switch does not physically control the power supply's access to the 110v AC power, as in the older-style power supplies. Instead, the power supply's on or off status is toggled by a PS_ON signal received on pin 14 of the ATX connector.

The PS_ON signal can be generated physically by the computer's power switch or electronically by the operating system. PS_ON is an active low signal, meaning that the power supply voltage outputs are disabled (the system is off) when the PS_ON is high (greater than or equal to 2.0v). This excludes the +5VSB (Standby) on pin 9, which is active whenever the power supply is connected to an AC power source. The power supply maintains the PS_ON signal at either 3.3v or 5v. This signal is then routed through the motherboard to the remote switch on the front of the case. When the switch is pressed, the PS_ON signal is grounded. When the power supply sees the PS_ON signal drop to 0.8v or less, the power supply (and system) is turned on. Thus, the remote switch in an ATX-style system (which includes NLX and SFX systems as well) carries up to only +5v of DC power, rather than the full 115v–230v AC current like that of the older AT/LPX form factors.

Caution

The continuous presence of the +5VSB signal on pin 9 of the ATX connector means that the motherboard is always receiving standby power from the power supply when connected to an AC source, even when the computer is turned off. As a result, it is even more crucial to unplug an ATX system from the power source before working inside the case than it is on an earlier model system.

Peripheral Power Connectors

In addition to the motherboard power connectors, power supplies include a variety of peripheral power connectors for everything from floppy and hard drives to internal case fans. The following sections discuss the various types of connectors you're likely to find in your PC.

Peripheral and Floppy Drive Power Connectors

The disk drive connectors on power supplies are fairly universal with regard to pin configuration and even wire color. Figure 21.18 shows the peripheral and floppy power connectors.

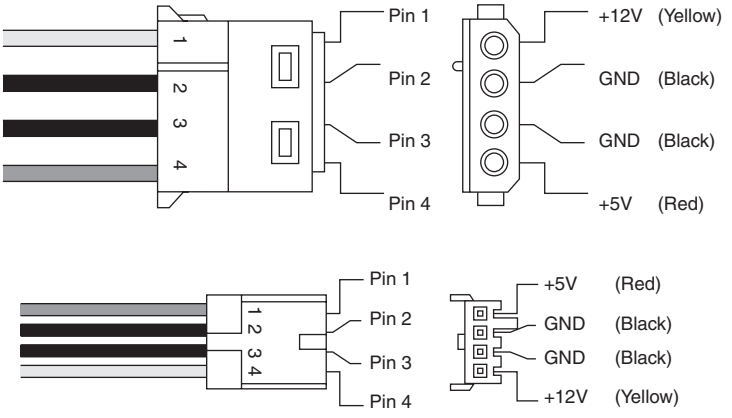

Figure 21.18 Peripheral and floppy power connectors.

Table 21.10 shows the standard disk drive power connector pinout and wire colors, whereas Table 21.11 shows the pinouts for the smaller floppy drive power connector.

Table 21.10 Peripheral Power Connector Pinout (Large Drive Power Connector)

Pin	Signal	Color	Pin	Signal	Color
1	+12v	Yellow	3	Gnd	Black
2	Gnd	Black	4	+5v	Red

Table 21.11 3 1/2" Floppy Power Connector Pinout (Small Drive Power Connector)

Pin	Signal	Color	Pin	Signal	Color
1	+5v	Red	3	Gnd	Black
2	Gnd	Black	4	+12v	Yellow

Note that the pin numbering and voltage designations are reversed on the two connectors. Be careful if you are making or using an adapter cable from one type of connector to another. Reversing the red and yellow wires will fry the drive or device you plug into.

To determine the location of pin 1, look at the connector carefully. It is usually embossed in the plastic connector body; however, it is often tiny and difficult to read. Fortunately, these connectors are keyed and therefore difficult to insert incorrectly. Figure 21.19 shows the keying with respect to pin numbers on the larger drive power connector.

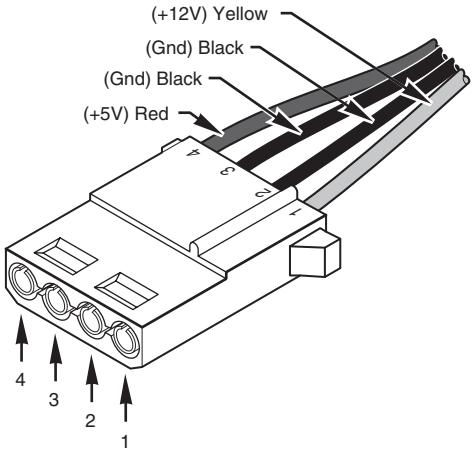

Figure 21.19 A peripheral female power supply connector.

Note

Some drive connectors might supply only two wires—usually the +5v and a single ground (pins 3 and 4)—because the floppy drives in most newer systems run only on +5v and do not use the +12v at all.

Early power supplies featured only two large style drive connectors, usually called peripheral connectors today. Later power supplies featured four or more of the larger peripheral (drive) connectors, and one or two of the smaller 3 1/2" floppy drive connectors. Depending on their power ratings and intended uses, some supplies have as many as eight peripheral/drive connectors.

If you are adding drives and need additional disk drive power connectors, Y splitter cables (see Figure 21.20) as well as large to small drive power connector adapters (see Figure 21.21) are available from many electronics supply houses (including RadioShack). These cables can adapt a single power connector to service two drives or enable you to convert the large peripheral power connector to a smaller floppy drive power connector. If you are using several Y-adapters, be sure that your total power supply output is capable of supplying the additional power.

Physical Connector Part Numbers

The physical connectors used in industry-standard PC power supplies were originally specified by IBM for the supplies used in the original PC/XT/AT systems. They used a specific type of connector between the power supply and the motherboard (the P8 and P9 connectors) and specific connectors for the disk drives. The motherboard connectors used in all the industry-standard power supplies were unchanged from 1981 (when the IBM PC appeared) until 1995 (when Intel released the ATX standard). The original PC's four-pin disk drive connector was augmented by a smaller (also four-pin) power connector when 3 1/2" floppy drives appeared in 1986. Table 21.12 lists the standard connectors used for motherboard and disk drive power.

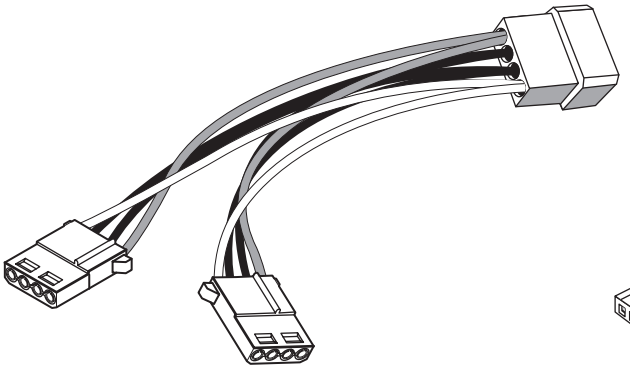

Figure 21.20 A common Y-adapter power cable.

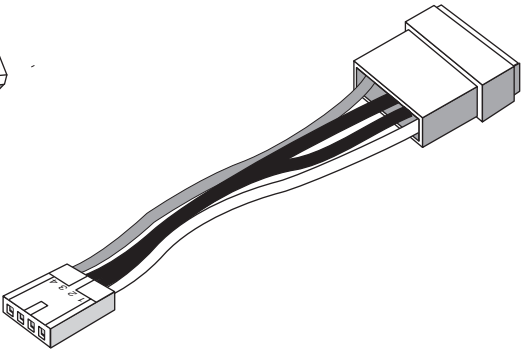

Figure 21.21 A peripheral–to–floppy drive power adapter cable.

Table 21.12 Physical Power Connectors

Connector Description	Female (on Power Cable)	Male (on Component)
ATX/NLX/SFX (20-pin)	Molex 39-01-2200	Molex 39-29-9202
ATX Optional (6-pin)	Molex 8993[1]	Molex 8619[2]
ATX12V Optional (4-pin)	Molex 39-01-2040	Molex 39-29-9042
PC/XT/AT/LPX P8/P9	Molex 8993[1]	Molex 8619[2]
Peripheral (large style)	AMP 1-480424-0	AMP 1-480426-0
Floppy drive (small style)	AMP 171822-4	AMP 171826-4

1. Can also use Burndy GTC6P-1

2. Can also use Burndy GTC6RI

You can get these raw connectors through the electronics supply houses (Allied, Newark, and Digi-Key, for example) found in the Vendor List on the DVD. You also can get complete cable assemblies, including drive adapters that convert the large connectors into small connectors, disk drive Y splitter cables, and motherboard power extension cables, from several of the cable and miscellaneous supply houses, such as Ci Design and Key Power, as well as PC Power and Cooling.

Caution

Before you install additional connectors to your power supply using Y splitters or any other type of connector, be sure your power supply is capable of delivering sufficient power for all your internal peripherals. Overloading the power supply can cause damage to electrical components and stored data.

▶▶ See "Power Supply Ratings," p. 1186.

Power Supply Specifications

Power supplies have several specifications that define their input and output capabilities as well as their operational characteristics. The following sections define and examine most of the common specifications related to power supplies.

Power Supply Loading

PC power supplies are of a *switching* rather than a *linear* design. The switching type of design uses a high-speed oscillator circuit to convert the higher wall-socket AC voltage to the much lower DC voltage used to power the PC and PC components. Switching-type power supplies are noted for being very efficient in size, weight, and energy in comparison to the linear design, which uses a large internal transformer to generate various outputs. This type of transformer-based design is inefficient in at least three ways. First, the output voltage of the transformer linearly follows the input voltage (hence the name *linear*), so any fluctuations in the AC power going into the system can cause problems with the output. Second, the high current-level (power) requirements of a PC system require the use of heavy wiring in the transformer. Third, the 60Hz frequency of the AC power supplied from your building is difficult to filter out inside the power supply, requiring large and expensive filter capacitors and rectifiers.

The switching supply, on the other hand, uses a switching circuit that chops up the incoming power at a relatively high frequency. This enables the use of high-frequency transformers that are much smaller and lighter. Also, the higher frequency is much easier and cheaper to filter out at the output, and the input voltage can vary widely. Input ranging from 90v to 135v still produces the proper output levels, and many switching supplies can automatically adjust to 220v input.

One characteristic of all switching-type power supplies is that they do not run without a *load*. Therefore, you must have something such as a motherboard and hard drive plugged in and drawing power for the supply to work. If you simply have the power supply on a bench with nothing plugged into it, either the supply burns up or its protection circuitry shuts it down. Most power supplies are protected from no-load operation and shut down automatically. Some of the cheapest supplies, however, lack the protection circuit and relay and can be destroyed after a few seconds of no-load operation. A few power supplies have their own built-in load resistors, so they can run even though there isn't a normal load (such as a motherboard or hard disk) plugged in.

Some power supplies have minimum load requirements for both the +5v and +12v sides. According to IBM specifications for the 192-watt power supply used in the original AT, a minimum load of 7.0 amps was required at +5v and a minimum of 2.5 amps was required at +12v for the supply to work properly. As long as a motherboard was plugged into the power supply, the motherboard would draw sufficient +5v at all times to keep those circuits in the supply happy. However, +12v is typically used only by motors (and not motherboards), and the floppy or CD/DVD drive motors are off most of the time. Because floppy or optical (CD/DVD) drives don't present any +12v load unless they are spinning, systems without a hard disk drive could have problems because there wouldn't be enough load on the +12v circuit in the supply.

To alleviate problems, when IBM used to ship the original AT systems without a hard disk, it plugged the hard disk drive power cable into a large 5-ohm, 50-watt sandbar resistor that was mounted in a small, metal cage assembly where the drive would have been. The AT case had screw holes on top of where the hard disk would go, specifically designed to mount this resistor cage.

Note

Several computer stores I knew of in the mid-1980s ordered the diskless AT and installed their own 20MB or 30MB drives, which they could get more cheaply from sources other than IBM. They were throwing away the load resistors by the hundreds! I managed to grab a couple at the time, which is how I know the type of resistor they used.

This resistor would be connected between pin 1 (+12v) and pin 2 (Ground) on the hard disk power connector. This placed a 2.4-amp load on the supply's +12v output, drawing 28.8 watts of power (it would get hot!) and thus enabling the supply to operate normally. Note that the cooling fan in most

power supplies draws approximately 0.1–0.25 amps, bringing the total load to 2.5 amps or more. If the load resistor were missing, the system would intermittently fail to start up.

Most of the power supplies in use today do not require as much of a load as the original IBM AT power supply. In most cases, a minimum load of 0–0.3 amps at +3.3v, 2.0–4.0 amps at +5v, and 0.5–1.0 amps at +12v is considered acceptable. Most motherboards easily draw the minimum +5v current by themselves. The standard power supply cooling fan draws only 0.1–0.25 amps, so the +12v minimum load might still be a problem for a diskless workstation. Generally, the higher the rating on the supply, the more minimum load required. However, exceptions do exist, so this is a specification you should check when evaluating power supplies.

Some switching power supplies have built-in load resistors and can run in a no-load situation. Most power supplies don't have internal load resistors but might require only a small load on the +5v line to operate properly. Some supplies, however, might require +3.3v, +5v, and +12v loads to work—the only way to know is by checking the documentation for the particular supply in question.

No matter what, if you want to properly and accurately bench test a power supply, be sure you place a load on at least one (or preferably all) of the positive voltage outputs. This is one reason it is best to test a supply while it is installed in the system, instead of testing it separately on the bench. For impromptu bench testing, you can use a spare motherboard and one or more hard disk drives to load the outputs.

Power Supply Ratings

A system manufacturer should be able to provide you the technical specifications of the power supplies it uses in its systems. This type of information can be found in the system's technical reference manual, as well as on stickers attached directly to the power supply. Power supply manufacturers can also supply this data, which is preferable if you can identify the manufacturer and contact them directly or via the Web.

The input specifications are listed as voltages, and the output specifications are listed as amps at several voltage levels. IBM reports output wattage level as "specified output wattage." If your manufacturer does not list the total wattage, you can convert amperage to wattage by using the following simple formula:

watts = volts×amps

For example, if a motherboard is listed as drawing 6 amps of +5v current, that equals 30 watts of power according to the formula.

By multiplying the voltage by the amperage available at each main output and then adding the results, you can calculate the total capable output wattage of the supply. Note that only positive voltage power signals are normally used in calculating outputs; the negative outputs, Standby, Power_Good, or other signals that are not used to power components are exempt.

Table 21.13 shows the standard power supply output levels available in industry-standard form factors. Most manufacturers offer supplies with ratings from 100 watts to 450 watts or more. Table 21.14 shows the rated outputs at each of the voltage levels for supplies with different manufacturer-specified output ratings. To compile the table, I referred to the specification sheets for supplies from Astec Power and PC Power and Cooling. Although most of the ratings are fairly accurate, there appears to be overly optimistic rounding going on in some of the ratings.

Table 21.13 Typical Non-ATX Power Supply Output Ratings

Rated Output (Watts)	100W	150W	200W	250W	300W	375W	450W
Output current (amps):							
+5v	10.0	15.0	20.0	25.0	32.0	35.0	45.0
+12v	3.5	5.5	8.0	10.0	10.0	13.0	15.0
–5v	0.3	0.3	0.3	0.5	0.5	0.5	1.0
–12v	0.3	0.3	0.3	0.5	0.5	0.5	1.0
Calc. output (watts)	92	141	196	245	280	331	405

Adding a +3.3v output to the power supply modifies the equation significantly. Table 21.14 contains data for various ATX/ATX12V power supplies from PC Power and Cooling.

Table 21.14 PC Power and Cooling ATX/ATX12V Power Supply Output Ratings

Model (Rated Output)	235W	250W	275W	300W	350W	400W	425W	475W
+3.3v	13	13	14	14	28	40	40	45
+5v	22	25	30	30	32	40	40	40
+12v	8	10	10	12	15	15	15	30
-5v	0.3	0.3	0.3	0.3	0.3	0.3	0.3	0.3
–12v	0.5	0.5	1.0	1.0	0.8	1.0	1.0	2.0
+5VSB	2.0	2.0	2.0	2.0	2.0	2.0	2.0	3.5
Total watts (3.3+5+12)*	249	288	316	340	432	512	512	709
+3.3v and +5v Max.	125	150	150	150	215	300	300	300

**Note the calculated maximum output is theoretical, assuming the maximum draw from the +3.3v, +5v, and +12v simultaneously. Virtually all power supplies place limits on the maximum combined draw for the +3.3v and +5v combined. This would make the true maximum rating somewhat less than the calculated maximum shown here.*

If you compute the total output using the formula described earlier, these power supplies seem to produce an output that is much higher than their ratings. The 300W model, for example, comes out at 340 watts. However, notice that the supply also has a maximum combined output for the +3.3v and +5v of 150 watts. This means you can't draw the maximum rating on both the +5v and +3.3v circuits simultaneously but must keep the total combined draw between them at 150W or less. This brings the total output to a more logical 294 watts.

Most PC power supplies have ratings between 150 and 300 watts. Although lesser ratings are not usually desirable, you can purchase heavy-duty power supplies for most systems that have outputs as high as 600 watts or more.

The 300-watt and larger units are recommended for fully optioned desktops or tower systems. These supplies run any combination of motherboard and expansion card, as well as a large number of disk drives and other peripherals. In most cases, you can't exceed the ratings on these power supplies—the system will run out of room for additional items first!

Most power supplies are considered to be universal, or worldwide. That is, they also can run on the 220v, 50-cycle current used in Europe and many other parts of the world. Many power supplies that can switch from 110v to 220v input do so automatically, but a few require you to set a switch on the back of the power supply to indicate which type of power you will access.

Caution

If your supply does not switch input voltages automatically, make sure the voltage setting is correct. If you plug the power supply into a 110v outlet while it's set in the 220v setting, no damage will result, but the supply won't operate properly until you correct the setting. On the other hand, if you plug into a 220v outlet and have the switch set for 110v, you can cause damage.

Other Power Supply Specifications

In addition to power output, many other specifications and features go into making a high-quality power supply. I have had many systems over the years. My experience has been that if a brownout occurs in a room with several systems running, the systems with higher-quality power supplies and higher output ratings are far more likely to make it through the power disturbances unscathed, whereas others choke.

High-quality power supplies also help protect your systems. A power supply from a vendor such as Astec or PC Power and Cooling will not be damaged if any of the following conditions occur:

- A 100% power outage of any duration
- A brownout of any kind
- A spike of up to 2,500v applied directly to the AC input (for example, a lightning strike or a lightning simulation test)

Decent power supplies have an extremely low current leakage to ground of less than 500 microamps. This safety feature is important if your outlet has a missing or an improperly wired ground line.

As you can see, these specifications are fairly tough and are certainly representative of a high-quality power supply. Make sure that your supply can meet these specifications.

You can also use many other criteria to evaluate a power supply. The power supply is a component many users ignore when shopping for a PC, and it is therefore one that some system vendors choose to skimp on. After all, a dealer is far more likely to be able to increase the price of a computer by spending money on additional memory or a larger hard drive than by installing a better power supply.

When buying a computer (or a replacement power supply), you always should learn as much as possible about the power supply. However, many consumers are intimidated by the vocabulary and statistics found in a typical power supply specification. Here are some of the most common parameters found on power supply specification sheets, along with their meanings:

- *Mean Time Between Failures (MTBF) or Mean Time To Failure (MTTF).* The (calculated) average interval, in hours, that the power supply is expected to operate before failing. Power supplies typically have MTBF ratings (such as 100,000 hours or more) that are clearly not the result of real-time empirical testing. In fact, manufacturers use published standards to calculate the results based on the failure rates of the power supply's individual components. MTBF figures for power supplies often include the load to which the power supply was subjected (in the form of a percentage) and the temperature of the environment in which the tests were performed.
- *Input Range (or Operating Range).* The range of voltages that the power supply is prepared to accept from the AC power source. For 110v AC current, an input range of 90v–135v is common; for 220v current, a 180v–270v range is typical.
- *Peak Inrush Current.* The greatest amount of current drawn by the power supply at a given moment immediately after it is turned on, expressed in terms of amps at a particular voltage. The lower the current, the less thermal shock the system experiences.

- *Hold-Up Time.* The amount of time (in milliseconds) that a power supply can maintain output within the specified voltage ranges after a loss of input power. This enables your PC to continue running without resetting or rebooting if a brief interruption in AC power occurs. Values of 15–30 milliseconds are common for today's power supplies, and the higher (longer), the better. The ATX12V specification calls for a minimum of 17ms hold-up time.
- *Transient Response.* The amount of time (in microseconds) a power supply takes to bring its output back to the specified voltage ranges after a steep change in the output current. In other words, the amount of time it takes for the output power levels to stabilize after a device in the system starts or stops drawing power. Power supplies sample the current being used by the computer at regular intervals. When a device stops drawing power during one of these intervals (such as when a floppy drive stops spinning), the power supply might supply too high a voltage to the output for a brief time. This excess voltage is called *overshoot*, and the transient response is the time that it takes for the voltage to return to the specified level. This is seen as a spike in voltage by the system and can cause glitches and lockups. Once a major problem that came with switching power supplies, overshoot has been greatly reduced in recent years. Transient response values are sometimes expressed in time intervals, and at other times they are expressed in terms of a particular output change, such as "power output levels stay within regulation during output changes of up to 20%."
- *Overvoltage Protection.* Defines the trip points for each output at which the power supply shuts down or squelches that output. Values can be expressed as a percentage (for example, 120% for +3.3 and +5v) or as raw voltages (for example, +4.6v for the +3.3v output and +7.0v for the +5v output).
- *Maximum Load Current.* The largest amount of current (in amps) that safely can be delivered through a particular output. Values are expressed as individual amperages for each output voltage. With these figures, you can calculate not only the total amount of power the power supply can supply, but also how many devices using those various voltages it can support.
- *Minimum Load Current.* The smallest amount of current (in amps) that must be drawn from a particular output for that output to function. If the current drawn from an output falls below the minimum, the power supply could be damaged or automatically shut down.
- *Load Regulation (or Voltage Load Regulation).* When the current drawn from a particular output increases or decreases, the voltage changes slightly as well—usually increasing as the current rises. Load regulation is the change in the voltage for a particular output as it transitions from its minimum load to its maximum load (or vice versa). Values, expressed in terms of a +/– percentage, typically range from +/–1% to +/–5% for the +3.3v, +5v, and +12v outputs.
- *Line Regulation.* The change in output voltage as the AC input voltage transitions from the lowest to the highest value of the input range. A power supply should be capable of handling any AC voltage in its input range with a change in its output of 1% or less.
- *Efficiency.* The ratio of power input to power output, expressed in terms of a percentage. Values of 65%–85% are common for power supplies today. The remaining 15%–35% of the power input is converted to heat during the AC/DC conversion process. Although greater efficiency means less heat inside the computer (always a good thing) and lower electric bills, it should not be emphasized at the expense of precision, stability, and durability, as evidenced in the supply's load regulation and other parameters.
- *Ripple (or Ripple and Noise, or AC Ripple, or PARD [Periodic and Random Deviation]).* The average voltage of all AC effects on the power supply outputs, usually measured in millivolts peak-to-peak or as a percentage of the nominal output voltage. The lower this figure, the better. Higher-quality units are typically rated at 1% ripple (or less), which if expressed in volts would be 1% of the output. Consequently, for +5v that would be 0.05v or 50mv (millivolts). Ripple

can be caused by internal switching transients, feed through of the rectified line frequency, and other random noise.

Power Factor Correction

Recently, the power line efficiency and harmonic distortion generation of PC power supplies has come under examination. This generally falls under the topic of the power factor of the supply. Interest in power factor is not only due to an improvement in power efficiency, but also because of a reduction in the generation of harmonics back on the power line. In particular, new standards are now mandatory in many European Union (EU) countries that require harmonics be reduced below a specific amount. The circuitry required to do this is called power factor correction (PFC).

The *power factor* measures how effectively electrical power is being used and is expressed as a number between 0 and 1. A high power factor means that electrical power is being used effectively, whereas a low power factor indicates poor utilization of electrical power. To understand the power factor, you must understand how power is used.

Generally, two types of loads are placed on AC power lines:

- *Resistive.* Power converted into heat, light, motion, or work
- *Inductive.* Sustains an electromagnetic field, such as in a transformer or motor

A resistive load is often called *working power* and is measured in kilowatts (KW). An inductive load, on the other hand, is often called *reactive power* and is measured in kilovolt-amperes-reactive (KVAR). Working power and reactive power together make up *apparent power*, which is measured in kilovolt-amperes (KVA). The power factor is measured as the ratio of working power to apparent power, or working power/apparent power (KW/KVA). The ideal power factor is 1, where the working power and apparent power are the same.

The concept of a resistive load or working power is fairly easy to understand. For example, a light bulb that consumes 100W of power generates 100W worth of heat and light. This is a pure resistive load. An inductive load, on the other hand, is a little harder to understand. Think about a transformer, which has coil windings to generate an electromagnetic field and then induce current in another set of windings. A certain amount of power is required to saturate the windings and generate the magnetic field, even though no work is being done. A power transformer that is not connected to anything is a perfect example of a pure inductive load. An apparent power draw exists to generate the fields, but no working power exists because no actual work is being done.

When the transformer is connected to a load, it uses both working power and reactive power. In other words, power is consumed to do work (for example, if the transformer is powering a light bulb), and apparent power is used to maintain the electromagnetic field in the transformer windings. In an AC circuit, these loads can become out of sync or phase, meaning they don't peak at the same time, which can generate harmonic distortions back down the power line. I've seen examples where electric motors have caused distortions in television sets plugged into the same power circuit.

PFC usually involves adding capacitance to the circuit to maintain the inductive load without drawing additional power from the line. This makes the working power and apparent power the same, which results in a power factor of 1. It usually isn't just as simple as adding some capacitors to a circuit, although that can be done and is called *passive* power factor correction. *Active* power factor correction involves a more intelligent circuit designed to match the resistive and inductive loads so they are seen as the same by the electrical outlet.

A power supply with active power factor correction draws low distortion current from the AC source and has a power factor rating of 0.9 or greater. A nonpower factor corrected supply draws highly

distorted current and is sometimes referred to as a *nonlinear* load. The power factor of a noncorrected supply is typically 0.6–0.8. Therefore, only 60% of the apparent power consumed is actually doing real work!

Having a power supply with active PFC might or might not lower your electric bill (it depends on how your power is measured), but it will definitely reduce the load on the building wiring. With PFC, all the power going into the supply is converted into actual work and the wiring is less overworked. For example, if you ran a number of computers on a single breaker-controlled circuit and found that you were blowing the breaker periodically, you could switch to systems with active PFC power supplies and reduce the load on the wiring by up to 40%, meaning you would be less likely to blow the breaker.

The International Electrical Committee (IEC) has released standards dealing with the low-frequency public supply system. The initial standards were 555.2 (Harmonics) and 555.3 (Flicker), but they have since been refined and are now available as IEC 1000-3-2 and IEC 1000-3-3, respectively. As governed by the EMC directive, most electrical devices sold within the member countries of the EU must meet the IEC standards. The IEC1000-3-2/3 standards became mandatory in 1997 and 1998.

Even if you don't live in a country where PFC is required, I highly recommend specifying PC power supplies with active PFC. The main benefits of PFC supplies is that they do not overheat building wiring or distort the AC source waveform, which causes less interference on the line for other devices.

Power Supply Safety Certifications

Many agencies around the world certify electric and electronic components for safety and quality. The most commonly known agency in the United States is Underwriters Laboratories, Inc. (UL). UL standard #1950—the *Standard for Safety of Information Technology Equipment, Including Electrical Business Equipment, Third Edition*—covers power supplies and other PC components. You should always purchase power supplies and other devices that are UL-certified. It has often been said that, although not every good product is UL-certified, no bad products are.

In Canada, electric and electronic products are certified by the Canadian Standards Agency (CSA). The German equivalents are TÜV Rheinland and VDE, and NEMKO operates in Norway. These agencies are responsible for certification of products throughout Europe. Power supply manufacturers that sell to an international market should have products that are certified at least by UL, the CSA, and TÜV—if not by all the agencies listed, and more.

Apart from UL-type certifications, many power supply manufacturers, even the most reputable ones, claim that their products have a Class B certification from the Federal Communications Commission, meaning that they meet FCC standards for electromagnetic and radio frequency interference (EMI/RFI). This is a contentious point, however, because the FCC does not certify power supplies as individual components. Title 47 of the Code of Federal Regulations, Part 15, Section 15.101(c) states as follows:

> "The FCC does NOT currently authorize motherboards, cases, and internal power supplies. Vendor claims that they are selling 'FCC-certified cases,' 'FCC-certified motherboards,' or 'FCC-certified internal power supplies' are false."

In fact, an FCC certification can be issued collectively only to a base unit consisting of a computer case, motherboard, and power supply. Thus, a power supply purported to be FCC-certified was actually certified along with a particular case and motherboard—not necessarily the same case and motherboard you are using in your system. This does not mean, however, that the manufacturer is being deceitful or that the power supply is inferior. If anything, this means that when evaluating power supplies, you should place less weight on the FCC certification than on other factors, such as UL certification.

Power-Use Calculations

When expanding or upgrading your PC, you should ensure that your power supply is capable of providing sufficient current to power all the system's internal devices. One way to see whether your system is capable of expansion is to calculate the levels of power drain in the various system components and deduct the total from the maximum power supplied by the power supply. This calculation can help you decide whether you must upgrade the power supply to a more capable unit. Unfortunately, these calculations can be difficult to make because many manufacturers do not publish power consumption data for their products.

In addition, getting power-consumption data for many +5v devices, including motherboards and adapter cards, can be difficult. Motherboards can consume different power levels, depending on numerous factors. Most motherboards consume about 5 amps or so, but try to get information on the one you are using. For adapter cards, if you can find the actual specifications for the card, use those figures. To be on the conservative side, however, I usually go by the maximum available power levels set forth in the respective bus standards.

For example, consider the power-consumption figures for components in a modern PC, such as a desktop or Slimline system with a 200-watt power supply rated for 20 amps at +5v and 8 amps at +12v. The ISA specification calls for a maximum of 2.0 amps of +5v power and 0.175 amps of +12v power for each slot in the system. Most systems have eight slots, and you can assume that four are filled for the purposes of calculating power draw. The calculation shown in Table 21.15 shows what happens when you subtract the amount of power necessary to run the various system components.

Table 21.15 Power Consumption Calculation

	Available 5v Power (Amps):	**20.0A**		**Available 12v Power (Amps):**	**8.0A**
Less:	Motherboard	–5.0A	Less:	4 slots filled at 0.175 each	–0.7A
	4 slots filled at 2.0 each	–8.0A		3 1/2'' hard disk drive motor	–1.0A
	3 1/2'' floppy drive logic	–0.5A		3 1/2'' floppy drive motor	–1.0A
	3 1/2'' hard disk drive logic	–0.5A		Cooling fan motor	–0.1A
	CD-ROM/DVD drive logic	–1.0A		CD-ROM/DVD drive motor	–1.0A
	Remaining Power (amps):	**5.0A**		**Remaining Power (amps):**	**4.2A**

In the preceding example, everything seems okay for now. With half the slots filled, a floppy drive, and one hard disk, the system still has room for more. Problems with the power supply could come up, however, if this system were expanded to the extreme. With every slot filled and two or more hard disks, problems with the +5v current definitely would occur. However, the +12v does seem to have room to spare. You could add a CD-ROM drive or a second hard disk without worrying too much about the +12v power, but the +5v power would be strained.

If you anticipate loading up a system to the extreme—as in a high-end multimedia system, for example—you might want to invest in the insurance of a higher-output power supply. For example, a 250-watt supply usually has 25 amps of +5v current and 10 amps of +12v current, whereas a 300-watt unit usually has 32 amps of +5v current available. These supplies enable you to fully load the system and are likely to be found in full-sized desktop or tower case configurations in which this type of expansion is expected.

Motherboards can draw anywhere from 4 to 15 amps or more of +5v power to run. In fact, a single Pentium 66MHz CPU draws up to 3.2 amps of +5v power all by itself. A 200MHz Pentium Pro CPU or 400MHz Pentium II consumes up to 15 amps. Considering that systems with two or more processors are now becoming common, you could have 30 amps or more drawn by the processors alone. A motherboard such as this—with two CPUs and 128MB or more of RAM for each CPU—might draw more than 40 amps all by itself. Very few "no-name" power supplies can supply this kind of current. For these applications, you should consider only high-quality, high-capacity power supplies from a reputable manufacturer, such as PC Power and Cooling.

In these calculations, bus slots are allotted maximum power in amps, as shown in Table 21.16.

Table 21.16 Maximum Power Consumption in Amps Per Bus Slot

Bus Type	+5v Power	+12v Power	+3.3v Power
ISA	2.0	0.175	n/a
EISA	4.5	1.5	n/a
VL-bus	2.0	n/a	n/a
16-bit MCA	1.6	0.175	n/a
32-bit MCA	2.0	0.175	n/a
PCI	5	0.5	7.6

As you can see from the table, ISA slots are allotted 2.0 amps of +5v and 0.175 amps of +12v power. Note that these are maximum figures; not all cards draw this much power. If the slot has a VL-bus extension connector, an additional 2.0 amps of +5v power are allowed for the VL-bus.

Floppy drives can vary in power consumption, but most of the newer 3 1/2" drives have motors that run on +5v current in addition to the logic circuits. These drives usually draw 1.0 amp of +5v power and use no +12v at all. 5 1/4" drives use standard +12v motors that draw about 1.0 amp. These drives also require about 0.5 amps of +5v for the logic circuits. Most cooling fans draw about 0.1 amps of +12v power, which is negligible.

Typical 3 1/2" hard disks today draw about 1 amp of +12v power to run the motors and only about 0.5 amps of +5v power for the logic. 5 1/4" hard disks, especially those that are full-height, draw much more power. A typical full-height hard drive draws 2.0 amps of +12v power and 1.0 amp of +5v power.

Another problem with hard disks is that they require much more power during the spin-up phase of operation than during normal operation. In most cases, the drive draws double the +12v power during spin-up, which can be 4.0 amps or more for the full-height drives. This tapers off to a normal level after the drive is spinning.

The figures that most manufacturers report for maximum power supply output are full duty-cycle figures. The power supply can supply these levels of power continuously. You usually can expect a unit that continuously supplies a given level of power to be capable of exceeding this level for some non-continuous amount of time. A supply normally can offer 50% greater output than the continuous figure indicates for as long as 1 minute. Systems often use this cushion to supply the necessary power to spin up a hard disk drive. After the drive has spun to full speed, the power draw drops to a value within the system's continuous supply capabilities. Drawing anything over the rated continuous figure for any extended length of time causes the power supply to run hot and fail early, and it can create nasty symptoms in the system.

Tip

If you are using internal SCSI hard drives, you can ease the startup load on your power supply. The key is to enable the SCSI drive's Remote Start option, which causes the drive to start spinning only when it receives a startup command over the SCSI bus. The effect is that the drive remains stationary (drawing very little power) until the very end of the POST and spins up right when the SCSI portion of the POST begins.

If you have multiple SCSI drives, they all spin up sequentially based on their SCSI ID settings. This is designed so that only one drive is spinning up at any one time and so that no drives start spinning until the rest of the system has had time to start. This greatly eases the load on the power supply when you first power the system on.

In most cases, you enable Remote Start through your SCSI host adapter's setup program. This program might be supplied with the adapter on separate media, or it might be integrated into the adapter's BIOS and activated with a specific key combination at boot time.

The biggest cause of power supply overload problems has historically been filling up the expansion slots and adding more drives. Multiple hard drives, CD-ROM drives, and floppy drives can create quite a drain on the system power supply. Be sure you have enough +12v power to run all the drives you plan to install. Tower systems can be especially problematic because they have so many drive bays. Just because the case has room for the devices doesn't mean the power supply can support them. Be sure you have enough +5v power to run all your expansion cards, especially PCI cards. It pays to be conservative, but remember that most cards draw less than the maximum allowed. Today's newest processors can have very high current requirements for the +5v or +3.3v supplies. When selecting a power supply for your system, be sure to take into account any future processor upgrades.

Many people wait until an existing component fails to replace it with an upgraded version. If you are on a tight budget, this "if it ain't broke, don't fix it" attitude might be necessary. Power supplies, however, often do not fail completely all at once; they can fail in an intermittent fashion or allow fluctuating power levels to reach the system, which results in unstable operation. You might be blaming system lockups on software bugs when the culprit is an overloaded power supply. In addition, an inadequate or failing supply causing lockups can result in file system corruption, which causes even further system instabilities (that could remain present even after replacing the power supply). If you have been running your original power supply for a long time and have upgraded your system in other ways, you should expect some problems, and you might want to consider reloading the operating system and applications from scratch.

Although there is certainly an appropriate place for the exacting power-consumption calculations you've read about in this section, a great many experienced PC users prefer the "don't worry about it" power calculation method. This technique consists of buying or building a system with a good-quality 300-watt or higher power supply (or upgrading to such a supply in an existing system) and then upgrading the system freely, without concern for power consumption.

Tip

My preference is the 425W supply from PC Power and Cooling, which is probably overkill for most people, but for those who keep a system for a long time and put it through several upgrades, it is an excellent choice.

Unless you plan to build a system with arrays of SCSI drives and a dozen other peripherals, you will probably not exceed the capabilities of the power supply, and this method certainly requires far less effort.

Power Cycling

Should you turn off a system when it is not in use? To answer this frequent question, you should understand some facts about electrical components and what makes them fail. Combine this knowledge with information on power consumption, cost, and safety to come to your own conclusion. Because circumstances can vary, the best answer for your own situation might be different from the answer for others, depending on your particular needs and applications.

Frequently powering a system on and off does cause deterioration and damage to the components. This seems logical, but the simple reason is not obvious to most people. Many believe that flipping system power on and off frequently is harmful because it electrically "shocks" the system. The real problem, however, is temperature or thermal shock. As the system warms up, the components expand; as it cools off, the components contract. In addition, various materials in the system have different thermal expansion coefficients, so they expand and contract at different rates. Over time, thermal shock causes deterioration in many areas of a system.

From a pure system-reliability viewpoint, you should insulate the system from thermal shock as much as possible. When a system is turned on, the components go from ambient (room) temperature to as high as 185°F (85°C) within 30 minutes or less. When you turn off the system, the same thing happens in reverse, and the components cool back to ambient temperature in a short period of time.

Thermal expansion and contraction remains the single largest cause of component failure. Chip cases can split, allowing moisture to enter and contaminate them. Delicate internal wires and contacts can break, and circuit boards can develop stress cracks. Surface-mounted components expand and contract at rates different from the circuit boards on which they are mounted, causing enormous stress at the solder joints. Solder joints can fail due to the metal hardening from the repeated stress, resulting in cracks in the joint. Components that use heatsinks, such as processors, transistors, or voltage regulators, can overheat and fail because the thermal cycling causes heatsink adhesives to deteriorate and break the thermally conductive bond between the device and the heatsink. Thermal cycling also causes socketed devices and connections to loosen, or *creep*, which can cause a variety of intermittent contact failures.

◀◀ See "SIMMs, DIMMs, and RIMMs," p. 435.

Thermal expansion and contraction affect not only chips and circuit boards, but also things such as hard disk drives. Most hard drives today have sophisticated thermal compensation routines that make adjustments in head position relative to the expanding and contracting platters. Most drives perform this thermal compensation routine once every 5 minutes for the first 30 minutes the drive is running and then every 30 minutes thereafter. In many drives, this procedure can be heard as a rapid "tick-tick-tick-tick" sound.

In essence, anything you can do to keep the system at a constant temperature prolongs the life of the system, and the best way to accomplish this is to leave the system either permanently on or permanently off. Of course, if the system is never turned on in the first place, it should last a long time indeed!

Now, I am not saying that you should leave all systems on 24 hours a day. A system powered on and left unattended can be a fire hazard (I have witnessed at least two monitors spontaneously catch fire—luckily, I was there at the time), is a data security risk (from cleaning crews and other nocturnal visitors), can be easily damaged if moved while running, and wastes electrical energy.

I currently pay 11 cents for a kilowatt-hour of electricity. A typical desktop-style PC with display consumes at least 300 watts (0.3 kilowatt) of electricity (and that is a conservative estimate). This means it would cost 3.3 cents to run my typical PC for an hour. Multiplying by 168 hours in a week means

that it would cost $5.54 per week to run this PC continuously. If the PC were turned on at 9 a.m. and off at 5 p.m., it would be on only 40 hours per week and would cost only $1.32—a savings of $4.22 per week! Multiply this savings by 100 systems, and you are saving $422 per week. Multiply this by 1,000 systems, and you are saving $4,220 per week! Using systems certified under the EPA Energy Star program (so-called green PCs) would account for an additional savings of around $1 per system per week—or $1,000 per week for 1,000 systems. The great thing about Energy Star systems is that the savings are even greater if the systems are left on for long periods of time because the power management routines are automatic.

Based on these facts, my recommendations are that you power on the systems at the beginning of the workday and off at the end of the workday. Do not power the systems off for lunch, breaks, or any other short periods of time. If you are a home user, leave your computer on if you are going to be using it later in the day or if instant access is important. I'd normally recommend home users turn off the system when leaving the house or when sleeping. Servers, of course, should be left on continuously. This seems to be the best compromise of system longevity with pure economics. No matter what, these are just guidelines; if it works better for you to leave your system on 24 hours a day, seven days a week, make it so.

Power Management

As the standard PC configuration has grown to include capabilities formerly considered options, the power requirements of the system have increased steadily. Larger displays, CD-ROM drives, and audio adapters all need more power to run, and the cost of operating a PC rises steadily. To address these concerns, several programs and standards are now being developed that are intended to reduce the power needed to run a PC as much as possible.

For standard desktop systems, power management is a matter of economy and convenience. By turning off specific components of the PC when they are not in use, you can reduce the electric bill and avoid having to power the computer up and down manually.

For portable systems, power management is far more important. Adding CD-ROMs, speakers, and other components to a laptop or notebook computer reduces even further what is in many cases a short battery life. By adding new power management technology, a portable system can supply power only to the components it actually needs to run, thus extending the life of the battery charge.

Energy Star Systems

The EPA has started a certification program for energy-efficient PCs and peripherals. To be a member of this program, the PC or display must drop to a power draw at the outlet of 30 watts or less during periods of inactivity. Systems that conform to this specification get to wear the Energy Star logo. This is a voluntary program; however, many PC manufacturers are finding that it helps them sell their systems if they can advertise these systems as energy efficient.

One problem with this type of system is that the motherboard and disk drives can go to sleep, which means they can enter a standby mode in which they draw very little power. This causes havoc with some of the older power supplies because the low power draw does not provide enough of a load for them to function properly. Most of the newer supplies on the market, which are designed to work with these systems, have a very low minimum-load specification. I suggest you ensure that the minimum load will be provided by the equipment in your system if you buy a power supply upgrade. Otherwise, when the PC goes to sleep, it might take a power switch cycle to wake it up again. This problem would be most noticeable if you invested in a very high-output supply and used it in a system that draws very little power to begin with.

Advanced Power Management

Advanced Power Management (APM) is a specification jointly developed by Intel and Microsoft that defines a series of interfaces between power management–capable hardware and a computer's operating system. When it is fully activated, APM can automatically switch a computer between five states, depending on the system's current activity. Each state represents a further reduction in power use, accomplished by placing unused components into a low-power mode. The five system states are as follows:

- *Full On.* The system is completely operational, with no power management occurring.
- *APM Enabled.* The system is operational, with some devices being power managed. Unused devices can be powered down and the CPU clock slowed or stopped.
- *APM Standby.* The system is not operational, with most devices in a low-power state. The CPU clock can be slowed or stopped, but operational parameters are retained in memory. When triggered by a specific user or system activity, the system can return to the APM Enabled state almost instantaneously.
- *APM Suspend.* The system is not operational, with most devices unpowered. The CPU clock is stopped, and operational parameters are saved to disk for later restoration. When triggered by a wake-up event, the system returns to the APM Enabled state relatively slowly.
- *Off.* The system is not operational. The power supply is off.

APM requires support from both hardware and software to function. In this chapter, you've already seen how ATX-style power supplies can be controlled by software commands using the Power_On signal and the six-pin optional power connector. Manufacturers are also integrating the same type of control features into other system components, such as motherboards, monitors, and disk drives.

Operating systems that support APM, such as Windows, trigger power management events by monitoring the activities performed by the computer user and the applications running on the system. However, the OS does not directly address the power management capabilities of the hardware.

A system can have many hardware devices and many software functions participating in APM functions, which makes communication difficult. To address this problem, both the operating system and the hardware have an abstraction layer that facilitates communication between the various elements of the APM architecture.

The operating system runs an APM driver that communicates with the various applications and software functions that trigger power management activities, while the system's APM-capable hardware devices all communicate with the system BIOS. The APM driver and the BIOS communicate directly, completing the link between the OS and the hardware.

Thus, for APM to function, support for the standard must be built into the system's individual hardware devices, the system BIOS, and the operating system (which includes the APM driver). Without all these components, APM activities can't occur.

Advanced Configuration and Power Interface

Advanced Configuration and Power Interface (ACPI) is a newer power management and system configuration standard supported by newer system BIOS software running Windows 98 and later operating systems. If your BIOS and operating system support ACPI, full power management control is now done by the operating system, rather than by the BIOS. ACPI is intended to offer a single place for power management and system configuration control; in the past, with APM you often could make power management settings in the BIOS setup as well as the operating system that overlapped or could have conflicting settings. ACPI is supported in newer systems in lieu of APM.

Tip

If, for any reason, you find that power management activities cause problems on your system, such as operating system freeze-ups or hardware malfunctions, the easiest way to disable APM is through the system BIOS. Most BIOSes that support APM include an option to disable it. This breaks the chain of communication between the operating system and the hardware, causing all power management activities to cease. Although you also can achieve the same end by removing the APM driver from the operating system, Windows 9x's Plug and Play (PnP) feature detects the system's APM capabilities whenever you restart the computer and attempts to reinstall the APM driver.

If you have a newer system with ACPI, you can disable the power management settings via the Power Management icon in the Windows Control Panel.

Power Supply Troubleshooting

Troubleshooting the power supply basically means isolating the supply as the cause of problems within a system and, if necessary, replacing it.

Caution

It is rarely recommended that an inexperienced user open a power supply to make repairs because of the dangerous high voltages present. Even when unplugged, power supplies can retain dangerous voltage and must be discharged (like a monitor) before service. Such internal repairs are beyond the scope of this book and are specifically not recommended unless the technician knows what she is doing.

Many symptoms lead me to suspect that the power supply in a system is failing. This can sometimes be difficult for an inexperienced technician to see because at times little connection seems to exist between the symptom and the cause—the power supply.

For example, in many cases a parity check error message can indicate a problem with the power supply. This might seem strange because the parity check message specifically refers to memory that has failed. The connection is that the power supply powers the memory, and memory with inadequate power fails.

It takes some experience to know when this type of failure is power related and not caused by the memory. One clue is the repeatability of the problem. If the parity check message (or other problem) appears frequently and identifies the same memory location each time, I would suspect that defective memory is the problem. However, if the problem seems random, or if the memory location the error message cites as having failed seems random, I would suspect improper power as the culprit. The following is a list of PC problems that often are related to the power supply:

- Any power-on or system startup failures or lockups
- Spontaneous rebooting or intermittent lockups during normal operation
- Intermittent parity check or other memory-type errors
- Hard disk and fan simultaneously failing to spin (no +12v)
- Overheating due to fan failure
- Small brownouts that cause the system to reset
- Electric shocks felt on the system case or connectors
- Slight static discharges that disrupt system operation

In fact, just about any intermittent system problem can be caused by the power supply. I always suspect the supply when flaky system operation is a symptom. Of course, the following fairly obvious symptoms point right to the power supply as a possible cause:

- System that is completely dead (no fan, no cursor)
- Smoke
- Blown circuit breakers

If you suspect a power supply problem, some of the simple measurements and the more sophisticated tests outlined in this section can help you determine whether the power supply is at fault. Because these measurements might not detect some intermittent failures, you might have to use a spare power supply for a long-term evaluation. If the symptoms and problems disappear when a known good spare unit is installed, you have found the source of your problem.

Following is a simple flowchart to help you zero in on common power supply–related problems:

1. Check the AC power input. Make sure the cord is firmly seated in the wall socket and in the power supply socket. Try a different cord.
2. Check the DC power connections. Make sure the motherboard and disk drive power connectors are firmly seated and making good contact. Check for loose screws.
3. Check the DC power output. Use a digital multimeter to check for proper voltages. If it's below spec, replace the power supply.
4. Check the installed peripherals. Remove all boards and drives and retest the system. If it works, add items back in one at a time until the system fails again. The last item added before the failure returns is likely defective.

Many types of symptoms can indicate problems with the power supply. Because the power supply literally powers everything else in the system, everything from disk drive problems to memory problems to motherboard problems can often be traced back to the power supply as the root cause.

Overloaded Power Supplies

A weak or inadequate power supply can put a damper on your ideas for system expansion. Some systems are designed with beefy power supplies, as if to anticipate a great deal of system add-ons and expansion components. Most desktop or tower systems are built in this manner. Some systems have inadequate power supplies from the start, however, and can't adequately service the power-hungry options you might want to add.

The wattage rating can sometimes be very misleading. Not all 300-watt supplies are created the same. People familiar with high-end audio systems know that some watts are better than others. This is true for power supplies, too. Cheap power supplies might in fact put out the rated power, but what about noise and distortion? Some of the supplies are under-engineered to just barely meet their specifications, whereas others might greatly exceed their specifications. Many of the cheaper supplies provide noisy or unstable power, which can cause numerous problems with the system. Another problem with under-engineered power supplies is that they can run hot and force the system to do so as well. The repeated heating and cooling of solid-state components eventually causes a computer system to fail, and engineering principles dictate that the hotter a PC's temperature, the shorter its life. Many people recommend replacing the original supply in a system with a heavier-duty model, which solves the problem. Because power supplies come in common form factors, finding a heavy-duty replacement for most systems is easy, as is the installation process.

Inadequate Cooling

Some of the available replacement power supplies have higher-capacity cooling fans than the originals, which can greatly prolong system life and minimize overheating problems—especially for the newer, hotter-running processors. If system noise is a problem, models with special fans can run more quietly than the standard models. These power supplies often use larger-diameter fans that spin more slowly, so they run more quietly but move the same amount of air as the smaller fans. PC Power and Cooling specializes in heavy-duty and quiet supplies; Astec has several heavy-duty models as well.

Ventilation in a system is also important. You must ensure adequate airflow to cool the hotter items in the system. Many systems today (especially those from larger vendors such as Dell, Gateway, MicronPC, and so on) still use passive heatsinks that require a steady stream of air to cool the chip. If the processor heatsink has its own fan, this is not much of a concern. If you have free expansion slots, you should space out the boards in your system to permit airflow between them. Place the hottest running boards nearest the fan or the ventilation holes in the system. Make sure that adequate airflow exists around the hard disk drive, especially for those that spin at high rates of speed. Some hard disks can generate quite a bit of heat during operation. If the hard disks overheat, data can be lost.

Always be sure you run your computer with the case cover on, especially if you have a loaded system using passive heatsinks. Removing the cover in that situation can actually cause the system to overheat. With the cover off, the power supply and chassis fans no longer draw air through the system. Instead, the fans end up cooling only the supply, and the rest of the system must be cooled by simple convection. Systems that use an active heatsink on the processor aren't as prone to this type of problem; in fact, the cooler air from outside the normally closed chassis can help them to run cooler.

In addition, be sure that any empty slot positions have the filler brackets installed. If you leave these brackets off after removing a card, the resultant hole in the case disrupts the internal airflow and can cause higher internal temperatures.

If you experience intermittent problems that you suspect are related to overheating, a higher-capacity replacement power supply is usually the best cure. Specially designed supplies with additional cooling fan capacity also can help. At least one company sells a device called a fan card, but I am not convinced these are a good idea. Unless the fan is positioned to draw air to or from outside the case, all it does is blow hot air around inside the system and provide a spot cooling effect for anything it is blowing on. In fact, adding fans in this manner contributes to the overall heat inside the system because the fan consumes power and generates heat.

CPU-mounted fans are an exception because they are designed only for spot cooling of the CPU. Most newer processors run so much hotter than the other components in the system that a conventional, passive heatsink can't do the job. In this case, a small fan placed directly over the processor provides a spot cooling effect that keeps the processor temperatures down. One drawback to these active processor cooling fans is that the processor overheats instantly and can be damaged if they fail. Newer Intel processors have built-in safeguards that prevent damage. The Pentium III, for example, automatically shuts down if overheated, and the Pentium 4 automatically throttles the speed down, which allows it to continue to run even if the heatsink is completely removed! Still, it is best not to depend on these safeguards because not all processors have them. Whenever possible, try to use a high-quality heatsink that is designed to properly cool your processor.

Using Digital Multimeters

One simple test you can perform on a power supply is to check the output voltages. This shows whether a power supply is operating correctly and whether the output voltages are within the correct tolerance range. Note that you must measure all voltages with the power supply connected to a

proper load, which usually means testing while the power supply is still installed in the system and connected to the motherboard and peripheral devices.

Selecting a Meter

You need a simple digital multimeter (DMM) or digital volt-ohm meter (DVOM) to perform voltage and resistance checks on electronic circuits (see Figure 21.22). You should use only a DMM instead of the older needle-type multimeters because the older meters work by injecting 9v into the circuit when measuring resistance, which damages most computer circuits.

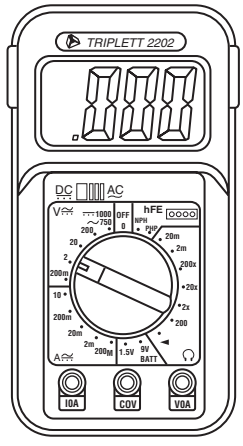

Figure 21.22 A typical DMM.

A DMM uses a much smaller voltage (usually 1.5v) when making resistance measurements, which is safe for electronic equipment. You can get a good DMM with many features from several sources. I prefer the small, pocket-size meters for computer work because they are easy to carry around.

Some features to look for in a good DMM are as follows:

- *Pocket size.* This is self-explanatory, but small meters are available that have many, if not all, of the features of larger ones. The elaborate features found on some of the larger meters are not really necessary for computer work.
- *Overload protection.* If you plug the meter into a voltage or current beyond the meter's capability to measure, the meter protects itself from damage. Cheaper meters lack this protection and can be easily damaged by reading current or voltage values that are too high.
- *Autoranging.* The meter automatically selects the proper voltage or resistance range when making measurements. This is preferable to the manual range selection; however, really good meters offer both autoranging capability and a manual range override.
- *Detachable probe leads.* The leads easily can be damaged, and sometimes a variety of differently shaped probes are required for different tests. Cheaper meters have the leads permanently attached, which means you can't easily replace them. Look for a meter with detachable leads that plug into the meter.
- *Audible continuity test.* Although you can use the ohm scale for testing continuity (0 ohms indicates continuity), a continuity test function causes the meter to produce a beep noise when

continuity exists between the meter test leads. By using the sound, you quickly can test cable assemblies and other items for continuity. After you use this feature, you will never want to use the ohms display for this purpose again.

- *Automatic power off.* These meters run on batteries, and the batteries can easily be worn down if the meter is accidentally left on. Good meters have an automatic shutoff that turns off the unit when it senses no readings for a predetermined period of time.
- *Automatic display hold.* This feature enables you to hold the last stable reading on the display even after the reading is taken. This is especially useful if you are trying to work in a difficult-to-reach area single-handedly.
- *Minimum and maximum trap.* This feature enables the meter to trap the lowest and highest readings in memory and hold them for later display, which is especially useful if you have readings that are fluctuating too quickly to see on the display.

Although you can get a basic pocket DMM for as little as $20, one with all these features is priced in the $100–$200 range. RadioShack carries some nice inexpensive units, and you can purchase the high-end models from electronics supply houses, such as Newark or Digi-Key.

Measuring Voltage

To measure voltages on a system that is operating, you must use a technique called *back probing* on the connectors (see Figure 21.23). You can't disconnect any of the connectors while the system is running, so you must measure with everything connected. Nearly all the connectors you need to probe have openings in the back where the wires enter the connector. The meter probes are narrow enough to fit into the connector alongside the wire and make contact with the metal terminal inside. The technique is called back probing because you are probing the connector from the back. You must use this back-probing technique to perform virtually all the following measurements.

To test a power supply for proper output, check the voltage at the Power_Good pin (P8-1 on AT, Baby-AT, and LPX supplies; pin 8 on the ATX-type connector) for +3v to +6v of power. If the measurement is not within this range, the system never sees the Power_Good signal and therefore does not start or run properly. In most cases, the power supply is bad and must be replaced.

Continue by measuring the voltage ranges of the pins on the motherboard and drive power connectors. If you are measuring voltages for testing purposes, any reading within 10% of the specified voltage is considered acceptable, although most manufacturers of high-quality power supplies specify a tighter 5% tolerance. For ATX power supplies, the specification requires that voltages must be within 5% of the rating, except for the 3.3v current, which must be within 4%. The following table shows the voltage ranges within these tolerances.

	Loose Tolerance		Tight Tolerance	
Desired Voltage	**Min. (–10%)**	**Max. (+8%)**	**Min. (–5%)**	**Max. (+5%)**
+3.3v	2.97v	3.63v	3.135	3.465
+/–5.0v	4.5v	5.4v	4.75	5.25
+/–12.0v	10.8v	12.9v	11.4	12.6

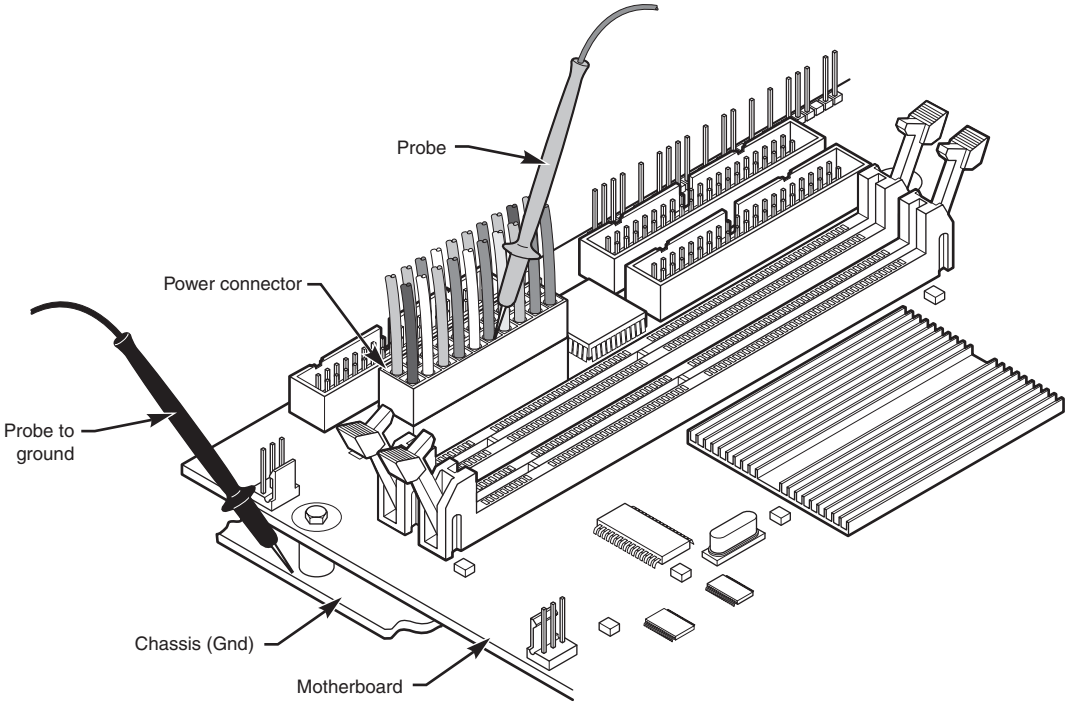

Figure 21.23 Back probing the power supply connectors.

The Power_Good signal has tolerances that are different from the other voltages, although it is nominally +5v in most systems. The trigger point for Power_Good is about +2.4v, but most systems require the signal voltage to be within the tolerances listed here:

Signal	Minimum	Maximum
Power_Good (+5v)	3.0v	6.0v

Replace the power supply if the voltages you measure are out of these ranges. Again, it is worth noting that any and all power supply tests and measurements must be made with the power supply properly loaded, which usually means it must be installed in a system and the system must be running.

Specialized Test Equipment

You can use several types of specialized test gear to test power supplies more effectively. Because the power supply is one of the most failure-prone items in PCs today, you should have these specialized items if you service many PC systems.

Digital Infrared Thermometer

One of the greatest additions to my toolbox is a digital infrared thermometer. They also are called noncontact thermometers because they measure by sensing infrared energy without having to touch the item they are reading. This enables me to make instant spot checks of the temperature of a chip, a board, or the system chassis. They are available from companies such as Raytek (`http://www.raytek.com`) for under $100. To use these handheld items, you point at an object and then pull

the trigger. Within seconds, the display shows a temperature readout accurate to +/–3°F (2°C). These devices are invaluable in checking to ensure the components in your system are adequately cooled.

Variable Voltage Transformer

When testing power supplies, it is sometimes desirable to simulate different AC voltage conditions at the wall socket to observe how the supply reacts. A variable voltage transformer is a useful test device for checking power supplies because it enables you to exercise control over the AC line voltage used as input for the power supply (see Figure 21.24). This device consists of a large transformer mounted in a housing with a dial indicator that controls the output voltage. You plug the line cord from the transformer into the wall socket and plug the PC power cord into the socket provided on the transformer. The knob on the transformer can be used to adjust the AC line voltage the PC receives.

Most variable transformers can adjust their AC outputs from 0v to 140v no matter what the AC input (wall socket) voltage is. Some can cover a range from 0v to 280v, as well. You can use the transformer to simulate brownout conditions, enabling you to observe the PC's response. Thus, you can check a power supply for proper Power_Good signal operation, among other things.

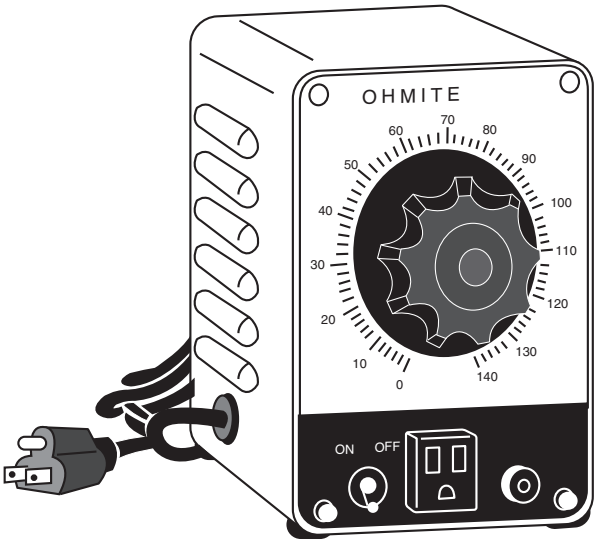

Figure 21.24 A variable voltage transformer.

By running the PC and dropping the voltage until the PC shuts down, you can see how much reserve is in the power supply for handling a brownout or other voltage fluctuations. If your transformer can output voltages in the 200v range, you can test the capability of the power supply to run on foreign voltage levels. A properly functioning supply should operate between 90v and 135v but should shut down cleanly if the voltage is outside that range.

One indication of a problem is seeing parity check-type error messages when you drop the voltage to 80v. This indicates that the Power_Good signal is not being withdrawn before the power supply output to the PC fails. The PC should simply stop operating as the Power_Good signal is withdrawn, causing the system to enter a continuous reset loop.

Variable voltage transformers are sold by a number of electronic parts supply houses, such as Newark and Digi-Key. You should expect to pay anywhere from $100 to $300 for this device.

Repairing the Power Supply

Hardly anyone actually repairs power supplies anymore, primarily because simply replacing the supply with a new one is usually cheaper. Even high-quality power supplies are not that expensive when compared to the labor required to repair them.

A defective power supply is typically discarded unless it happens to be one of the higher-quality or more expensive units. In that case, it is usually wise to send the supply to a company that specializes in repairing power supplies and other components. These companies normally provide what is called depot repair, which means you send the supply to them and they repair it and return it to you. If time is of the essence, most of the depot repair companies immediately send you a functional equivalent to your defective supply and take yours in as a core charge. Depot repair is the recommended way to service many PC components, such as power supplies, monitors, and printers. If you take your PC to a conventional service outlet, they often determine which component has the problem and send it to be depot repaired. You can do that yourself and save the markup the repair shop usually charges in such cases.

For those with experience around high voltages, you might be able to repair a failing supply with two relatively simple operations (replacing the internal fuse or the fan); however, these require opening the supply—something I do not normally recommend. I mention it only as an alternative to replacement in some cases. Besides, in all cases where I've seen the internal fuse blown, there were more serious problems and just replacing the fuse only caused it to immediately blow again. On the other hand, if the only problem with the supply is that the fan has failed (motor or bearing failure), you might be able to save the supply from the trash by simply replacing the internal fan.

Most manufacturers try to prevent you from entering the supply by sealing it with special tamperproof Torx screws. These screws use the familiar Torx star driver but also have a tamper-prevention pin in the center that prevents a standard driver from working. Most tool companies, such as Jensen or Specialized, sell sets of TT (tamperproof Torx) bits that remove the tamper-resistant screws. Other manufacturers rivet the power supply case shut, which means you must drill out the rivets to gain access.

Caution

The manufacturers place these obstacles there for a reason—to prevent entry by those who are inexperienced with high voltage. Consider yourself warned!

Obtaining Replacement Units

Most of the time, it is simply easier, safer, or less expensive (considering the time and materials involved) to replace the power supply than to repair it. As mentioned earlier, replacement power supplies are available from many manufacturers. Before you can shop for a supplier, however, you should consider other purchasing factors.

Deciding on a Power Supply

When you are shopping for a new power supply, you should take several factors into account. First, consider the power supply's shape, or form factor. ATX supplies are consistent in size, so any ATX supply should fit any ATX chassis. Some systems use the smaller SFX supplies, and those are available from third-party suppliers as well.

Apart from electrical considerations, power supply form factors can differ physically in their sizes, shapes, screw-hole positions, connector types, number of connectors, fan locations, and switch

positions. However, systems that use the same form factor can easily interchange power supplies. When ordering a replacement supply, you need to know which form factor your system requires.

Some systems use proprietary power supply designs, which makes replacement more difficult. If a system uses one of the common form factor power supplies, replacement units are available from hundreds of vendors. An unfortunate user of a system with a nonstandard form factor supply does not have this kind of choice and must get a replacement from the original manufacturer of the system—and usually must pay through the nose for the unit. Although you can find standard form factor supplies for under $100, the proprietary units from some manufacturers cost as much as $400 or more. PC buyers often overlook this and discover too late the consequences of having nonstandard components in a system.

◀◀ See "Power Supply Form Factors," p. 1159.

Cheaper retail-store systems are notorious for using proprietary form factor power supplies. Even Dell has been using proprietary supplies in many of its systems. Be sure you consider this if you intend to own these types of systems out of warranty. Personally, I always insist on systems that use industry-standard power supplies, such as the ATX form factor supply found in many systems today.

Sources for Replacement Power Supplies

Because one of the most failure-prone items in PC systems is the power supply, I am often asked to recommend a replacement. Literally hundreds of companies manufacture PC power supplies, and I certainly have not tested them all. I can, however, recommend some companies whose products I have come to know and trust.

Although other high-quality manufacturers exist, at this time I recommend power supplies from either Astec Power or PC Power and Cooling.

Astec makes the power supplies used in most of the high-end systems by IBM, Hewlett-Packard, Apple, and many other name-brand systems. Its power supplies are available in several standard form factors (AT/Tower, Baby-AT, LPX, and ATX) and a variety of output levels. Astec offers power supplies with ratings of up to 450 watts as well as power supplies designed especially for Green PCs, which meet the EPA Energy Star requirements for low-power consumption. Astec's Green power supplies are specifically designed to achieve high efficiency at low-load conditions. Be aware, however, that high-output supplies from other manufacturers might have problems with very low loads. Astec also makes a number of power supplies for laptop and notebook PC systems and has numerous non-PC-type supplies.

PC Power and Cooling has a complete line of power supplies for PC systems. It makes supplies in all the standard PC form factors used today. Versions are available in a variety of quality and output levels, from inexpensive replacements to very high-quality, high-output models with ratings of up to 600–850 watts. It even makes versions with built-in battery backup and redundant power systems, as well as a series of special models with high-volume, low-speed (quiet) fan assemblies. Its quiet models are especially welcome to people who work in quiet homes or offices and are annoyed by the fan noise some power supplies emanate. My favorite models are PC Power and Cooling's top-of-the-line 400W Silencer and the 475W Turbo-Cool ATX supplies, which have specs that put most others to shame.

PC Power and Cooling also has units available that fit some of Dell's proprietary designs. This can be a real boon if you have to service or repair Dell systems purchased between 1996 and 2000 because the PC Power and Cooling units are available in higher output ratings than Dell's. These units cost much less than Dell's and bolt in as direct replacements.

Tip

PC Power and Cooling also has SFX-style supplies that can be used to upgrade systems with Flex-ATX boards and chassis, including E-machines and other low-cost systems. If you have one of these systems and need a high-quality replacement supply to support your upgrades, PC Power and Cooling can help.

The support offered by PC Power and Cooling is excellent as well, and the company has been in business a long time—which is rare in this industry. Besides power supplies, it also offers an excellent line of cases.

A high-quality power supply from either of these vendors can be one of the best cures for intermittent system problems and can go a long way toward ensuring trouble-free operation in the future.

Chassis/Case

The components of a PC system are mounted within a chassis or case. The main feature you must first decide on is which form factor the case needs to be. Several somewhat standardized form factors are available for PC chassis, including

- Slimline Desktop
- Desktop
- Mini-Tower
- Mid-Tower
- Full Tower (Server)
- Large Server
- Rackmount

The Slimline chassis are typically used with NLX form factor boards that are a riser card design. Recently, an addendum to the ATX form factor was created that enables riser cards to be used, allowing ATX boards to be used even in Slimline systems.

In addition to the case form factor, the following are several other things you should consider before purchasing your case:

- *Motherboard form factor supported.* A given chassis usually accepts one or more standard motherboard form factors. Most of the chassis accept ATX (or Micro-ATX or Flex-ATX) form factor motherboards, whereas some accept Baby-AT form factor motherboards as well.
- *Motherboard mounting mechanism.* Some chassis include removable plates or trays that allow the board to be mounted outside the chassis. This enables the board to be more easily installed and facilitates easier servicing later.
- *Power supply form factor supported.* Most modern chassis support ATX or SFX form factor power supplies.
- *Power supply included or separate.* Many include the power supply as standard, but others do not. Usually, I prefer cases in which the supply is separate because that enables me to choose the specific power supply myself.
- *Number of 3 1/2'' drive bays (internal and external).* Hard drives are typically installed in the internal 3 1/2" drive bays, whereas floppy, LS-120, Zip, and some tape drives are installed in external 3 1/2" bays.

- *Number of 5 1/4" drive bays (external).* CD and DVD drives as well as some tape drives install in 5 1/4" drive bays, which are almost always external.
- *Number and size of cooling fans supported.* Most modern cases have mounting provisions for several additional cooling fans of different sizes. Be sure the case you choose has sufficient fan mounting provisions to provide the cooling your system will require.
- *Ease of disassembly (tool-free or not).* Some cases are easily disassembled without the use of tools, whereas others require simple hand tools.
- *Front panel USB supported.* Many newer cases feature front-mounted USB connectors, which are a major convenience.

These are just some of the criteria you should use when selecting the case for your next system.

Custom Cases

Sometimes the standard cases don't fit the bill; in those situations you might want to investigate using a more specialized or custom case. Several companies make specialized cases for unique systems. These cases offer features such as multiple drive bays, unique appearances, and specialized cooling.

Perhaps the most unique cases on the market are those by Kryotech (`www.kryotech.com`) or Chip-Con (`www.chip-con.com`). These companies market cases with built-in refrigeration units in the base, which are connected directly to a thermal plate that mounts on the CPU. The plate runs at temperatures as low as –40°F (–40°C) and can maintain a CPU temperature in the –18°F (–28°C) range with processors generating up to 150W. These cases also feature an LCD temperature display on the front for monitoring the temperature, and a safety system shutdown is designed to trip if the processor overheats. They have models available for Socket A through Socket 478 processors.

The only drawback to these cases is the expense; they cost about $500 each. They also do not include a power supply, which would cost another $100–$200 for something 300W or greater to go with it.

Another company offering special cases is PC Power and Cooling. It offers a line of heavy-duty, solid steel cases with multiple drive bays for serious expansion and server use. For those who want something that's different and sure to evoke stares from all who see it, PC Power and Cooling also offers a tower case with a chrome-plated front bezel and black cover.

Power-Protection Systems

Power-protection systems do just what the name implies: They protect your equipment from the effects of power surges and power failures. In particular, power surges and spikes can damage computer equipment, and a loss of power can result in lost data. In this section, you learn about the four primary types of power-protection devices available and when you should use them.

Before considering any further levels of power protection, you should know that a quality power supply already affords you a substantial amount of protection. High-end power supplies from the vendors I recommend are designed to provide protection from higher-than-normal voltages and currents, and they provide a limited amount of power-line noise filtering. Some of the inexpensive aftermarket power supplies probably do not have this sort of protection. If you have an inexpensive computer, further protecting your system might be wise.

Caution

All the power-protection features in this chapter and the protection features in the power supply inside your computer require that the computer's AC power cable be connected to a ground.

Many older homes do not have three-prong (grounded) outlets to accommodate grounded devices.

Do not use a three-pronged adapter (that bypasses the three-prong requirement and enables you to connect to a two-prong socket) to plug a surge suppressor, computer, or UPS into a two-pronged outlet. They often don't provide a good ground and can inhibit the capabilities of your power-protection devices.

You also should test your power sockets to ensure they are grounded. Sometimes outlets, despite having three-prong sockets, are not connected to a ground wire; an inexpensive socket tester (available at most hardware stores) can detect this condition.

Of course, the easiest form of protection is to turn off and unplug your computer equipment (including your modem) when a thunderstorm is imminent. However, when this is not possible, other alternatives are available.

Power supplies should stay within operating specifications and continue to run a system even if any of these power line disturbances occur:

- Voltage drop to 80v for up to 2 seconds
- Voltage drop to 70v for up to .5 seconds
- Voltage surge of up to 143v for up to 1 second

Most high-quality power supplies (or the attached systems) will not be damaged by the following occurrences:

- Full power outage
- Any voltage drop (brownout)
- A spike of up to 2,500v

Because of their internal protection, many computer manufacturers that use high-quality power supplies state in their documentation that external surge suppressors are not necessary with their systems.

To verify the levels of protection built into the existing power supply in a computer system, an independent laboratory subjected several unprotected PC systems to various spikes and surges of up to 6,000v—considered the maximum level of surge that can be transmitted to a system through an electrical outlet. Any higher voltage would cause the power to arc to the ground within the outlet. None of the systems sustained permanent damage in these tests. The worst thing that happened was that some of the systems rebooted or shut down when the surge was more than 2,000v. Each system restarted when the power switch was toggled after a shutdown.

I do not use any real form of power protection on my systems, and they have survived near-direct lightning strikes and powerful surges. The most recent incident, only 50 feet from my office, was a direct lightning strike to a brick chimney that blew the top of the chimney apart. None of my systems (which were running at the time) were damaged in any way from this incident; they just shut themselves down. I was able to restart each system by toggling the power switches. An alarm system located in the same office, however, was destroyed by this strike. I am not saying that lightning strikes or even much milder spikes and surges can't damage computer systems—another nearby lightning strike did destroy a modem and serial adapter installed in one of my systems. I was just lucky that the destruction did not include the motherboard.

This discussion points out an important oversight in some power-protection strategies: Do not forget to provide protection from spikes and surges on the phone line.

The automatic shutdown of a computer during power disturbances is a built-in function of most high-quality power supplies. You can reset the power supply by flipping the power switch from on to off and back on again. Some power supplies even have an auto-restart function. This type of power supply acts the same as others in a massive surge or spike situation: It shuts down the system. The difference is that after normal power resumes, the power supply waits for a specified delay of 3–6 seconds and then resets itself and powers the system back up. Because no manual switch resetting is required, this feature might be desirable in systems functioning as network servers or in those found in other unattended locations.

The first time I witnessed a large surge cause an immediate shutdown of all my systems, I was extremely surprised. All the systems were silent, but the monitor and modem lights were still on. My first thought was that everything was blown, but a simple toggle of each system-unit power switch caused the power supplies to reset, and the units powered up with no problem. Since that first time, this type of shutdown has happened to me several times, always without further problems.

The following types of power-protection devices are explained in the sections that follow:

- Surge suppressors
- Phone-line surge protectors
- Line conditioners
- Standby power supplies (SPS)
- Uninterruptible power supplies (UPS)

Surge Suppressors (Protectors)

The simplest form of power protection is any one of the commercially available surge protectors—that is, devices inserted between the system and the power line. These devices, which cost between $20 and $200, can absorb the high-voltage transients produced by nearby lightning strikes and power equipment. Some surge protectors can be effective for certain types of power problems, but they offer only very limited protection.

Surge protectors use several devices, usually metal-oxide varistors (MOVs), that can clamp and shunt away all voltages above a certain level. MOVs are designed to accept voltages as high as 6,000v and divert any power above 200v to ground. MOVs can handle normal surges, but powerful surges such as direct lightning strikes can blow right through them. MOVs are not designed to handle a very high level of power and self-destruct while shunting a large surge. These devices therefore cease to function after either a single large surge or a series of smaller ones. The real problem is that you can't easily tell when they no longer are functional. The only way to test them is to subject the MOVs to a surge, which destroys them. Therefore, you never really know whether your so-called surge protector is protecting your system.

Some surge protectors have status lights that let you know when a surge large enough to blow the MOVs has occurred. A surge suppressor without this status indicator light is useless because you never know when it has stopped protecting.

Underwriters Laboratories has produced an excellent standard that governs surge suppressors, called UL 1449. Any surge suppressor that meets this standard is a very good one and definitely offers a line of protection beyond what the power supply in your PC already offers. The only types of surge suppressors worth buying, therefore, should have two features:

- Conformance to the UL 1449 standard
- A status light indicating when the MOVs are blown

Units that meet the UL 1449 specification say so on the packaging or directly on the unit. If this standard is not mentioned, it does not conform. Therefore, you should avoid it.

Another good feature to have in a surge suppressor is a built-in circuit breaker that can be manually reset rather than a fuse. The breaker protects your system if it or a peripheral develops a short. These better surge suppressors usually cost about $40.

Phone Line Surge Protectors

In addition to protecting the power lines, it is critical to provide protection to your systems from any connected phone lines. If you are using a modem or fax board that is plugged into the phone system, any surges or spikes that travel through the phone line can damage your system. In many areas, the phone lines are especially susceptible to lightning strikes, which are the leading cause of fried modems and damage to the computer equipment attached to them.

Several companies manufacture or sell simple surge protectors that plug in between your modem and the phone line. These inexpensive devices can be purchased from most electronics supply houses. Most of the cable and communication product vendors listed in the Vendor List (on the DVD that accompanies this book) sell these phone line surge protectors. Some of the standard power line surge protectors include connectors for phone line protection as well.

Line Conditioners

In addition to high-voltage and current conditions, other problems can occur with incoming power. The voltage might dip below the level needed to run the system, resulting in a brownout. Forms of electrical noise other than simple voltage surges or spikes might travel through the power line, such as radio-frequency interference or electrical noise caused by motors or other inductive loads.

Remember two things when you wire together digital devices (such as computers and their peripherals):

- Any wire can act as an antenna and have voltage induced in it by nearby electromagnetic fields, which can come from other wires, telephones, CRTs, motors, fluorescent fixtures, static discharge, and, of course, radio transmitters.
- Digital circuitry responds with surprising efficiency to noise of even a volt or two, making those induced voltages particularly troublesome. The electrical wiring in your building can act as an antenna, picking up all kinds of noise and disturbances.

A line conditioner can handle many of these types of problems. A line conditioner is designed to remedy a variety of problems. It filters the power, bridges brownouts, suppresses high-voltage and current conditions, and generally acts as a buffer between the power line and the system. A line conditioner does the job of a surge suppressor, and much more. It is more of an active device, functioning continuously, rather than a passive device that activates only when a surge is present. A line conditioner provides true power conditioning and can handle myriad problems. It contains transformers, capacitors, and other circuitry that can temporarily bridge a brownout or low-voltage situation. These units usually cost $100–$300, depending on the power-handling capacity of the unit.

Backup Power

The next level of power protection includes backup power-protection devices. These units can provide power in case of a complete blackout, thereby providing the time necessary for an orderly system shutdown. Two types are available: the standby power supply (SPS) and the uninterruptible power supply (UPS). The UPS is a special device because it does much more than just provide backup power—it is also the best kind of line conditioner you can buy.

Standby Power Supplies

A standby power supply is known as an offline device: It functions only when normal power is disrupted. An SPS system uses a special circuit that can sense the AC line current. If the sensor detects a loss of power on the line, the system quickly switches over to a standby battery and power inverter. The power inverter converts the battery power to 110v AC power, which is then supplied to the system.

SPS systems do work, but sometimes a problem occurs during the switch to battery power. If the switch is not fast enough, the computer system shuts down or reboots anyway, which defeats the purpose of having the backup power supply. A truly outstanding SPS adds to the circuit a ferroresonant transformer, which is a large transformer with the capability to store a small amount of power and deliver it during the switch time. This device functions as a buffer on the power line, giving the SPS almost uninterruptible capability.

SPS units also might have internal line conditioning of their own. Under normal circumstances, most cheaper units place your system directly on the regular power line and offer no conditioning. The addition of a ferroresonant transformer to an SPS gives it extra regulation and protection capabilities because of the buffer effect of the transformer. SPS devices without the ferroresonant transformer still require the use of a line conditioner for full protection. SPS systems usually cost between a couple hundred and several thousand dollars, depending on the quality and power-output capacity.

Uninterruptible Power Supplies

Perhaps the best overall solution to any power problem is to provide a power source that is conditioned and that can't be interrupted—which is the definition of an uninterruptible power supply. UPSes are known as online systems because they continuously function and supply power to your computer systems. Because some companies advertise ferroresonant SPS devices as though they were UPS devices, many now use the term *true UPS* to describe a truly online system. A true UPS system is constructed in much the same way as an SPS system; however, because the computer is always operating from the battery, there is no switching circuit.

In a true UPS, your system always operates from the battery. A voltage inverter converts from 12v DC to 110v AC. You essentially have your own private power system that generates power independently of the AC line. A battery charger connected to the line or wall current keeps the battery charged at a rate equal to or greater than the rate at which power is consumed.

When the AC current supplying the battery charger fails, a true UPS continues functioning undisturbed because the battery-charging function is all that is lost. Because the computer was already running off the battery, no switch takes place and no power disruption is possible. The battery begins discharging at a rate dictated by the amount of load your system places on the unit, which (based on the size of the battery) gives you plenty of time to execute an orderly system shutdown. Based on an appropriately scaled storage battery, the UPS functions continuously, generating power and preventing unpleasant surprises. When the line power returns, the battery charger begins recharging the battery, again with no interruption.

Note

Occasionally, a UPS can accumulate too much storage and not enough discharge. When this occurs, the UPS emits a loud alarm, alerting you that it's full. Simply unplugging the unit from the AC power source for a while can discharge the excess storage (as it powers your computer) and drain the UPS of the excess.

Many SPS systems are advertised as though they are true UPS systems. The giveaway is the unit's switch time. If a specification for switch time exists, the unit can't be a true UPS because UPS units

never switch. However, a good SPS with a ferroresonant transformer can virtually equal the performance of a true UPS at a lower cost.

Note

Many UPSes today come equipped with a cable and software that enables the protected computer to shut down in an orderly manner on receipt of a signal from the UPS. This way, the system can shut down properly even if the computer is unattended. Some operating systems designed for server environments, such as Windows NT/2000/XP, contain their own UPS software components.

UPS cost is a direct function of both the length of time it can continue to provide power after a line current failure and how much power it can provide. You therefore should purchase a UPS that provides enough power to run your system and peripherals and enough time to close files and provide an orderly shutdown. Remember, however, to manually perform a system shutdown procedure during a power outage. You will probably need your monitor plugged into the UPS and the computer. Be sure the UPS you purchase can provide sufficient power for all the devices you must connect to it.

Because of a true UPS's almost total isolation from the line current, it is unmatched as a line conditioner and surge suppressor. The best UPS systems add a ferroresonant transformer for even greater power conditioning and protection capability. This type of UPS is the best form of power protection available. The price, however, can be high. To find out just how much power your computer system requires, look at the UL sticker on the back of the unit. This sticker lists the maximum power draw in watts, or sometimes in just volts and amperes. If only voltage and amperage are listed, multiply the two figures to calculate the wattage.

As an example, if the documentation for a system indicates that the computer can require as much as 110v at a maximum current draw of 5 amps, the maximum power the system can draw is about 550 watts. This wattage is for a system with every slot full, two hard disks, and one floppy—in other words, a system at the maximum possible level of expansion. The system should never draw any more power than that; if it does, a 5-amp fuse in the power supply will blow. This type of system usually draws an average of 300 watts. However, to be safe when you make calculations for UPS capacity, be conservative; use the 550-watt figure. Adding a monitor that draws 100 watts brings the total to 650 watts or more. Therefore, to run two fully loaded systems, you'd need a 1,100-watt UPS. And don't forget two monitors, each drawing 100 watts. Therefore, the total is 1,300 watts. A UPS of that capacity or greater costs approximately $500–$700. Unfortunately, that is what the best level of protection costs. Most companies can justify this type of expense only for critical-use PCs, such as network servers.

Note

The highest-capacity UPS sold for use with a conventional 15-amp outlet is about 1,400 watts. If it's any higher, you risk tripping a 15-amp circuit when the battery is charging heavily and the inverter is drawing maximum current.

In addition to the total available output power (wattage), several other factors can distinguish one UPS from another. The addition of a ferroresonant transformer improves a unit's power conditioning and buffering capabilities. Good units also have an inverter that produces a true sine wave output; the cheaper ones might generate a square wave. A square wave is an approximation of a sine wave with abrupt up-and-down voltage transitions. The abrupt transitions of a square wave are not compatible with some computer equipment power supplies. Be sure that the UPS you purchase produces power that is compatible with your computer equipment. Every unit has a specification for how long it can sustain output at the rated level. If your systems draw less than the rated level, you have some additional time.

Caution

Be careful! Most UPS systems are not designed for you to sit and compute for hours through an electrical blackout. They are designed to provide power only to essential components and to remain operating long enough to allow for an orderly shutdown. You pay a large amount for units that provide power for more than 15 minutes or so. At some point, it becomes more cost-effective to buy a generator than to keep investing in extended life for a UPS.

Some of the many sources of power protection equipment include American Power Conversion (APC), Tripp Lite, and Best Power. These companies sell a variety of UPS, SPS, line, and surge protector products.

Caution

Don't connect a laser printer to a backed-up socket in any SPS or UPS unit. Such printers are electrically noisy and have widely varying current draws. This can be hard on the inverter in an SPS or a UPS and frequently cause the inverter to fail or detect an overload and shut down. Either case means that your system will lose power, too.

Printers are normally noncritical because whatever is being printed can be reprinted. Don't connect them to a UPS unless there's a good business need to do so.

Some UPSes and SPSes have sockets that are conditioned but not backed up—that is, they do not draw power from the battery. In cases such as this, you can safely plug printers and other peripherals into these sockets.

RTC/NVRAM (CMOS RAM) Batteries

All 16-bit and higher systems have a special type of chip in them that combines a real-time clock (RTC) with at least 64 bytes (including the clock data) of nonvolatile RAM (NVRAM) memory. This chip is officially called the RTC/NVRAM chip, but it is often referred to as the CMOS or CMOS RAM chip because the type of chip used is produced using a CMOS (complementary metal-oxide semiconductor) process. CMOS design chips are known for very low power consumption. This special RTC/NVRAM chip is designed to run off a battery for several years.

The original chip of this type used in the IBM AT was the Motorola MC146818 chip. Although the chips used today have different manufacturers and part numbers, they all are designed to be compatible with this original Motorola part. Most modern motherboards have the RTC/NVRAM built into the motherboard chipset South Bridge or I/O Controller Hub (ICH) component.

The function of the real-time clock should be obvious: The clock enables software to read the date and time and preserves the date and time data even when the system is powered off or unplugged.

The NVRAM portion of the chip has another function. It is designed to store basic system configuration, including the amount of memory installed, types of floppy and hard disk drives, and other information. Some of the more modern motherboards use extended NVRAM chips with as much as 4KB or more of space to hold this configuration information. This is especially true for plug-and-play systems, which store the motherboard configuration as well as the configuration of adapter cards. The system can then read this information every time you power it on.

These chips typically are powered by some type of battery while the system is off. This battery preserves the information in the NVRAM and powers the clock. Most systems use a lithium-type battery because they have a very long life, especially at the low power draw from the typical RTC/NVRAM chip.

Some systems have a chip that has the battery embedded within it. These are made by several companies—including Dallas Semiconductor and Benchmarq. These chips are notable for their long lives. Under normal conditions, the integral battery lasts for 10 years—which is, of course, longer than the useful life of the system. If your system uses one of the Dallas or Benchmarq modules, the battery and chip must be replaced as a unit because they are integrated. Most of the time, these chip/battery combinations are installed in a socket on the motherboard just in case a problem requires an early replacement. You can get new modules direct from the manufacturers for $18 or less, which is often less than the cost of the older separate battery alone.

Some systems do not use a battery at all. Hewlett-Packard, for example, includes a special capacitor in some of its systems that is automatically recharged anytime the system is plugged in. Note that the system does not have to be running for the capacitor to charge; it only has to be plugged in. If the system is unplugged, the capacitor powers the RTC/NVRAM chip for up to a week or more. If the system remains unplugged for a duration longer than that, the NVRAM information is lost. In that case, these systems can reload the NVRAM from a backup kept in a special flash ROM chip contained on the motherboard. The only pieces of information that will actually be missing when you repower the system are the date and time, which will have to be reentered. By using the capacitor combined with an NVRAM backup in flash ROM, these systems have a very reliable solution that lasts indefinitely.

Many systems use a separate battery, which can be either directly soldered into the motherboard (mostly older obsolete systems) or plugged in via a battery connector. For those older systems with the battery soldered in, a spare battery connector exists on the motherboard where you can insert a conventional plug-in battery, should the original ever fail.

Motherboard NVRAM (CMOS RAM) batteries come in many forms. The best are of a lithium design because they last 2–5 years or more. I have seen systems with conventional alkaline batteries mounted in a holder; these are much less desirable because they fail more frequently and do not last as long. Also, they are prone to leak, and if a battery leaks on the motherboard, the motherboard can be severely damaged. By far, the most commonly used battery for motherboards today is the type 2032 lithium coin cell battery, which is about the size of a quarter and is readily available at electronics supply stores, camera shops, and even drugstores.

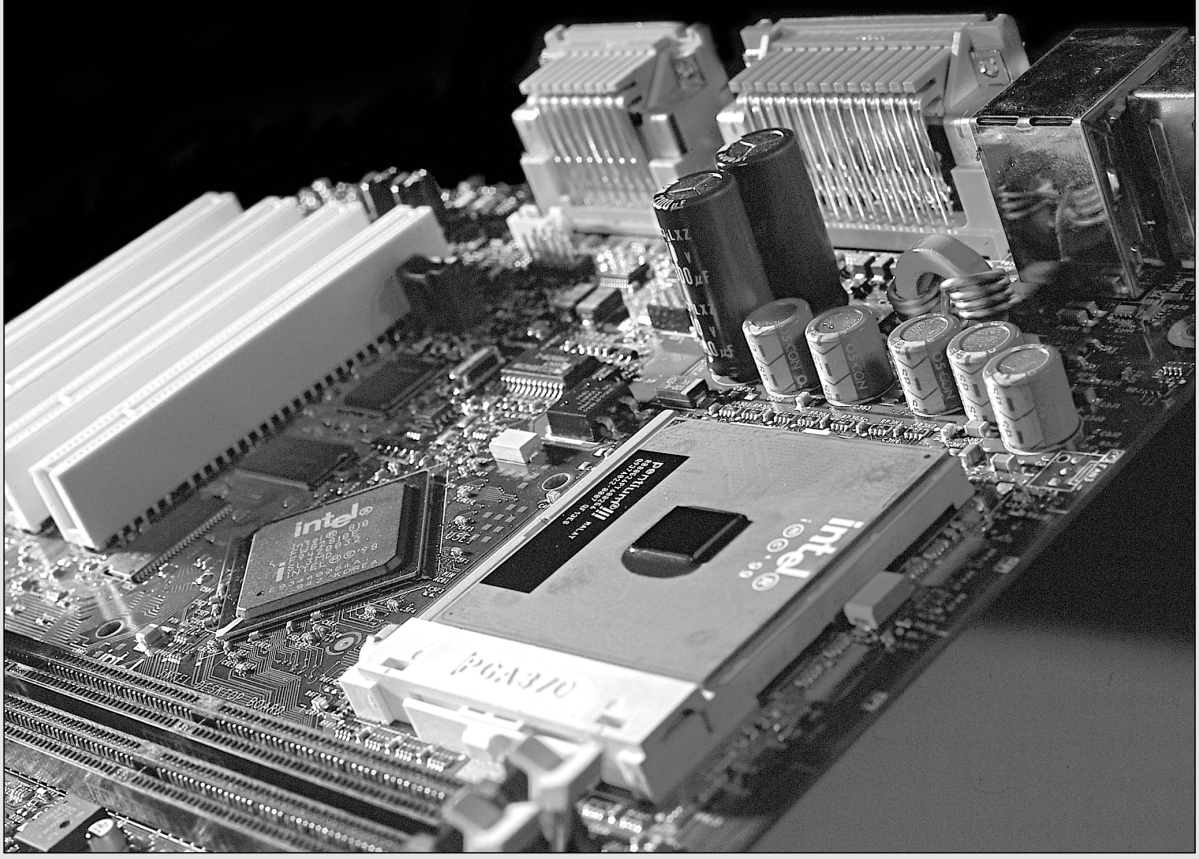
Besides the various battery types, the chip can require any one of several voltages. The batteries in PCs are usually 3.0v, but some systems have used 3.6v, 4.5v, or 6v types as well. If you are replacing the battery, be sure your replacement is the same voltage as the one you removed from the system. Some motherboards can use batteries of several voltages, and you use a jumper or switch to select the various settings. If you suspect your motherboard has this capability, consult the documentation for instructions on changing the settings. Of course, the easiest thing to do is to replace the existing battery with another of the same type.

Symptoms that indicate that the battery is about to fail include having to reset the clock on your PC every time you shut down the system (especially after moving it) and problems during the system's POST, such as drive-detection difficulties. If you experience problems such as these, you should make note of your system's CMOS settings and replace the battery as soon as possible.

Caution

When you replace a PC battery, be sure you get the polarity correct; otherwise, you will damage the RTC/NVRAM (CMOS) chip. Because the chip is soldered onto most motherboards, this can be an expensive mistake! The battery connector on the motherboard and the battery are usually keyed to prevent a backward connection. The pinout of this connector is on the DVD, but it should also be listed in your system documentation.

When you replace a battery, in most cases the existing data stored in the NVRAM is lost. Sometimes, however, the data remains intact for several minutes (I have observed NVRAM retain information with no power for an hour or more), so if you make the battery swap quickly, the information in the NVRAM might be retained. Just to be sure, I recommend that you record all the system configuration settings stored in the NVRAM by your system Setup program. In most cases, you should run the BIOS Setup program and copy or print out all the screens showing the various settings. Some Setup programs offer the capability to save the NVRAM data to a file for later restoration if necessary.



Tip

If your system BIOS is password-protected and you forget the password, one possible way to bypass the block is to remove the battery for a few minutes and then replace it. This resets the BIOS to its default settings, removing the password protection.

After replacing a battery, power up the system and use the Setup program to check the date and time setting and any other data that was stored in the NVRAM.

CHAPTER 22

Building or Upgrading Systems

System Components

In these days of commodity parts and component pricing, building your own system from scratch is no longer the daunting process it once was. Every component necessary to build a PC system is available off the shelf at competitive pricing. In many cases, the system you build can use the same or even better components than the top name-brand systems.

There are, however, some cautions to heed. The main thing to note is that you rarely save money when building your own system; purchasing a complete system from a mail-order vendor or mass merchandiser is almost always less expensive. The reason for this is simple: Most system vendors who build systems to order use many, if not all, of the same components you can use when building your own system. The difference is that they buy these components in quantity and receive a much larger discount than you can by purchasing only one of a particular item.

In addition, you pay only one shipping and handling charge when you purchase a complete system instead of the multiple shipping charges you pay when you purchase separate components. In fact, the shipping, handling, and phone charges from ordering all the separate parts needed to build a PC through the mail often add up to $100 or more. This cost rises if you encounter problems with any of the components and have to make additional calls or send improper or malfunctioning parts back for replacement. Many companies charge restocking fees if you purchase something and then determine you don't need it or can't use it.

If you purchase parts locally, you typically must pay the additional state sales tax, as well as the higher prices usually associated with retail store sales.

Then there is the included software. Although I can sometimes come close in price to a commercial system when building my own from scratch, the bundled software really adds value to the commercial system. An upgrade copy of Windows XP costs $100 or more, and most commercial systems also include Microsoft Office or other applications as well. Many commercial systems come with $250–$500 or more worth of software, depending on what they include.

It is clear that the reasons for building a system from scratch often have less to do with saving money and more to do with the experience you gain and the results you achieve. In the end, you have a custom system that contains the exact components and features you have selected. Most of the time when you buy a preconfigured system, you have to compromise in some way. For example, you might get the video adapter you want, but you would prefer a different make or model of motherboard. By building your own system, you can select the exact components you want and build the ultimate system for your needs. The experience is also very rewarding. You know exactly how your system is constructed and configured because you have done it yourself. This makes future support and installation of additional accessories much easier.

Another benefit of building your own system is that you are guaranteed a nonproprietary system that will be easily upgradable in the future. Of course, if you have been reading the book up to this point, you already know everything you need to ensure any preassembled systems you purchase would be nonproprietary and, therefore, upgradable and repairable in the future.

You might be able to save some money using components from your current system when building your new system. You might have recently upgraded your hard drive and optical drive in an attempt to extend the life of your current computer. In most cases, you can take those components with you to the new system. For example, if you bought a 120GB hard drive and a DVD+RW drive for your old system, you can move them to a newer system.

The good news is that your monitor, keyboard, mouse, and storage devices—as well as most AGP video cards and all PCI-based add-on cards—from your old system will work in your new system. The

bad news is that most newer systems require a memory type different from an older system and some AGP cards might not work in newer motherboards.

So, if you are interested in a rewarding experience, want a customized and fully upgradable system that is not exactly the same as that offered by any vendor, are able to take on all system repair and troubleshooting tasks, want to save some money by reusing some of the components from your current system, and are not in a hurry, building your own PC might be the way to go. On the other hand, if you are interested in getting a PC with the most value for the best price, want one-stop support for in-warranty repairs and technical problems, and need an operational system quickly, building your own system should definitely be avoided.

This chapter details the components necessary to assemble your own system, explains the assembly procedures, and lists some recommendations for components and their sources.

The components used in building a typical PC are

- Case and power supply
- Motherboard
- Processor with heatsink
- Memory
- Floppy drive
- Hard disk drive
- Optical drives (CD and/or DVD)
- Keyboard and pointing device (mouse)
- Video card and display
- Sound card and speakers
- Modem or LAN card (Internet/email access)
- Cooling fans and heatsinks
- Cables
- Hardware (nuts, bolts, screws, and brackets)
- Operating system software (on CD-ROM)

Each of these components is discussed in the following sections.

Case and Power Supply

The case and power supply are typically sold as a unit, although some vendors do sell them separately. There are a multitude of designs from which to choose, usually dependent on the motherboard form factor you want to use, the number of drive bays available, and whether the system is desktop or floor mounted. There are cases with extra fans for cooling (recommended), air filters on the air inlets to keep out the dust, removable side panels, or motherboard trays; cases that require no tools for assembly, rack-mounted versions, and more. For most custom-built systems, an ATX mid-tower case and power supply is the recommended choice. Cases designed for the older Baby-AT motherboard form factor are still available, but the ATX architecture offers considerable improvements. The size and shape of the case, power supply, and even the motherboard are called the *form factor*. The most popular case form factors are

- Full-tower
- Mini-tower
- Desktop
- Low-profile (also called Slimline)

Cases that take ATX boards are found mostly in the full-tower, mini-tower, and desktop form factors. When deciding which type of case to purchase, you should consider where you will place your computer. Will it be on a desk? Or is it more feasible to put the system on the floor and just have the monitor, keyboard, and mouse on the desk? The amount of space you have available for the computer can affect other purchasing decisions, such as the length of the monitor, keyboard, and mouse cables.

Of the choices listed, it is recommended that you avoid the low-profile systems. Designed primarily for use in business environments, these Slimline systems have a smaller footprint, meaning that they take up less space on your desk than the typical desktop computer and usually are not designed with expansion in mind. These cases require a special type of motherboard called a Low Profile or LPX board. The low-profile version of the ATX form factor is called the NLX. LPX and NLX motherboards often have virtually everything built in, including video, sound, and even network adapters.

LPX and NLX motherboards do not have any normal adapter slots. Instead, all the expansion slots are mounted on an adapter board called a *riser card*, which plugs into a special slot on the motherboard. Standard PCI or ISA adapter cards then plug sideways into the riser card (parallel to the motherboard), making expansion difficult and somewhat limited. In addition, the small size of the case makes working inside the machine difficult. Some designs force you to remove some components to gain access to others, making system maintenance inconvenient.

◀◀ See "Motherboard Form Factors," p. 202.

Most newer cases accept ATX-style boards, which have become the standard for Athlon and Pentium III/4–based systems. If you are interested in the most flexible type of case and power supply that will support the widest variety of future upgrades, I recommend sticking with the ATX-style cases and power supplies.

Note

Generally, any ATX case, motherboard, and power supply of sufficient wattage for your equipment can be put together to form the basis of a new system. However, there are two major exceptions you need to know about:

- *Dell motherboards and power supplies built from 1996 through 2000 use the standard ATX power supply physical connector but have changed the pinout and voltage levels.* If you mix a Dell motherboard and a standard power supply, or a standard motherboard and a Dell power supply, you will destroy the power supply and possibly your motherboard as well! If you want to upgrade newer Dell systems, you must either buy Dell-compatible power supplies for use with the Dell motherboard or replace both Dell components with standard ATX components. See Chapter 21, "Power Supply and Chassis/Case," for more details.
- *Intel's Pentium 4 CPU requires a heavy heatsink and fan for cooling.* To prevent motherboard damage, Intel specifies a modified ATX case design that uses the case, rather than the motherboard, to support the weight of the heatsink and fan. Some Pentium 4 motherboards come with a special baseplate designed to support the heatsink in standard ATX cases. The Pentium 4 also requires a different type of auxiliary power connector to supply the additional power needed by the CPU. Pentium 4–ready power supplies are available, or you can add an adapter to your existing high-output power supplies to provide adequate power for the Pentium 4.

Whether you choose a desktop or one of the tower cases is really a matter of personal preference and system location. Most people feel that the tower systems are roomier and easier to work on, and the full-sized tower cases have lots of bays for various storage devices. Tower cases typically have enough bays to hold floppy drives, multiple hard disk drives, CD-ROM drives, tape drives, and anything else you might want to install. However, some of the desktop cases can have as much room as the towers, particularly the mini- or mid-tower models. In fact, a tower case is sometimes considered a desktop case turned sideways or vice versa. Some cases are convertible—that is, they can be used in either a desktop or tower orientation.

Tip

Mini-tower or micro-tower systems are an exception to the roomy tower case rule. These systems normally use the Micro-ATX motherboard and might have only two or three drive bays. These systems are almost as difficult to work on as a Slimline system.

When it comes to the power supply, the most important consideration is how many devices you plan to install in the system and how much power they require. Chapter 21 describes the process for calculating the power your system hardware requires and selecting an appropriate power supply for your needs.

◀◀ See "Power-Use Calculations," p. 1192.

When you build your own system, you should always keep upgradability in mind. A properly designed custom PC should last you far longer than an off-the-shelf model because you can more easily add and substitute new components. When choosing a case and power supply, leave yourself some room for expansion, on the assumption that you will eventually need another hard drive or that some new device will appear on the market that you won't be able to live without. To be specific, be sure you have at least two empty drive bays for internal drives and choose a larger power supply than you need for your current onboard equipment.

Motherboard

Several compatible form factors are used for motherboards. The form factor refers to the physical dimensions and size of the board and dictates into which type of case the board will fit. The types of compatible industry-standard motherboard form factors generally available for system builders are as follows:

Obsolete form factors

- Baby-AT
- Full-size AT
- LPX (semiproprietary)

Modern form factors

- ATX
- Micro-ATX
- Flex-ATX
- NLX

All others

- Proprietary designs (some Compaq, Dell Optiplex, Hewlett-Packard, notebook/portable systems, and so on); Dell Dimension from 1996 through 2000 use ATX form factors, but with different electrical pinouts

The ATX motherboard design is far and away the most popular and best motherboard design for most people building their own systems today. ATX is an open architecture that improves on the older Baby-AT design in many ways that affect other components of the computer, such as the case and power supply. An ATX motherboard has the same basic dimensions as a Baby-AT; however, it is rotated 90° in the case from the standard Baby-AT orientation. This places the expansion slots parallel to the short side of the board, allowing more space for other components without interfering with expansion boards.

Components that produce large amounts of heat, such as the CPU and memory, are located next to the power supply for better cooling and easier access to the processor and memory sockets. ATX motherboards feature a high degree of port integration, but unlike Baby-AT motherboards, all ATX external ports are built into the motherboard and are mounted to one side of the expansion slots. You won't need to use the clumsy and easily damaged or disconnected ribbon cables used by Baby-AT motherboards to carry mouse, serial, parallel, or USB ports to the rear of the system.

The ATX-style power supply features a redesigned, single-keyed (foolproof!) connector that can't be plugged in backward or off-center. Plugging power supply connectors backward or off-center by a pin is easy to do in the Baby-AT design, and the result is catastrophic: The motherboard is destroyed the moment the power is turned on. This is impossible with the shrouded and keyed ATX power connector. This power supply provides the motherboard with the 3.3v current used by many of the newer CPUs and other components. ATX power supplies are also designed to support the advanced power-management features now found in system BIOSes and operating systems.

The micro-ATX form factor is a further development of the ATX design, intended for use in lower-cost systems. The micro-ATX architecture is backward-compatible with ATX and specifies a motherboard that is physically smaller, as the name implies. These smaller motherboards can be installed in standard ATX cases or in smaller cases specifically designed for the micro-ATX boards.

Other form factors used in motherboards today are the LPX and NLX form factors. These form factors require the use of a low-profile case and usually are not recommended when building your own system. This is because of the number of variations on case and riser-card designs, the limited expandability imposed by the motherboard and case architecture, and the difficulty of working in such a small space. Some LPX motherboards use a vertical riser card to mount expansion slots parallel to the motherboard, whereas others use a T-shaped riser card that lifts the expansion slots above the motherboard.

Because of the differences among systems with LPX motherboards, upgrading the motherboard on a system that uses an LPX motherboard is very difficult. The NLX form factor is another open standard Intel developed, with features comparable to the ATX but defining a Slimline-style case and motherboard arrangement. Systems based on the NLX standard should not experience the compatibility problems of LPX-based systems, but the inherent problems of the Low-Profile design remain. These types of form factors are popular with corporate clients and novice consumers because of the systems' small footprint and the "everything-on-the-motherboard" design. However, replacement NLX motherboards are relatively scarce compared to the abundance of ATX and micro-ATX motherboards on the market.

Note

For more information on all the motherboard form factors, see Chapter 4, "Motherboards and Buses." You can also find the reference standard documents detailing the modern form factors at the Desktop Form Factors Web site: `http://www.formfactors.org`.

In addition to the form factor, you should consider several other features when selecting a motherboard. The following sections examine each feature.

Processor

In some cases, your motherboard comes with the processor already installed. Some of the motherboard vendors like to install the processor and warranty the board and processor as a unit. This is not always the case, especially with slot-type processors because they are easier to ship with the processor removed. Most companies that sell motherboards like to sell you the processor at the same time and will give you some type of discount when you buy both. In some cases, you will get an extended warranty on the CPU and motherboard only if they are assembled and tested by the vendor. Even so, you can purchase the motherboard and processor separately if you want.

The motherboards you consider should have one of the following processor sockets or slots:

- *Socket A*. Supports the AMD Athlon and Duron processors
- *Socket 478*. Supports the second-generation Intel Pentium 4 processors
- *Socket 603*. Supports the Intel Xeon (Pentium 4–based) processors (typically used in servers)

The following slot and socket types also can be purchased but are not being supported by the latest CPU models and will limit your future processor upgrade options:

- *Slot 1 (also called SC-242)*. Supports the slot versions of the Intel Pentium III, Celeron, and Pentium II processors.
- *Slot 2 (also called SC-330)*. Supports the Intel Pentium III Xeon and Pentium II Xeon processors
- *Socket 7 (also called Super7 if faster than 66MHz)*. Supports the Intel Pentium; Pentium MMX; AMD K5, K6, K6-2, and K6-3; Cyrix 6x86 and 6x86MX; and MII processors
- *Slot A*. Supports the original AMD Athlon processors
- *Socket 370 (also called PGA370)*. Supports the socketed versions of the Intel Pentium III and Celeron processors
- *Socket 423*. Supports the initial versions of the Intel Pentium 4 processor

Because the motherboard you choose dictates or limits your choice in processor, you should choose your processor first. These days the choice in processors runs the gamut from the AMD Duron and Intel Celeron on the low end to the AMD Athlon and Intel Pentium 4 on the high end. For more information on these and all other processors, see Chapter 3, "Microprocessor Types and Specifications."

◀◀ See "Processor Socket and Slot Types," p. 89.

Depending on the type of motherboard you select, there might be jumpers on the motherboard to set. It also might have jumpers to control the voltage supplied to the processor. Typically, Socket 7 or Super7 boards have jumpers for motherboard bus speed, CPU multiplier, and CPU voltage settings. If you purchase this type of board, be sure you get these settings correct; otherwise, the system won't

run properly. In a worst-case situation, you can damage the processor with too high a voltage setting, for example.

All modern processor sockets handle these settings automatically, so there is little danger of incorrect settings. Even so, several boards have overrides for the automatic settings, which can be useful for those intending on hotrodding or overclocking their processors. Most of these boards use the BIOS Setup to control these overrides, so no jumpers or switches need to be set.

Chipsets

Aside from the processor, the main component on a motherboard is called the *chipset*. This usually is a set of one to five chips that contains the main motherboard circuits. These chipsets replace the 150 or more distinct components that were used in the original IBM AT systems and enable a motherboard designer to easily create a functional system from just a few parts. The chipset contains all the motherboard circuitry except the processor and memory in most systems.

Because the chipset really *is* the motherboard, the chipset used in a given motherboard has a profound effect on the performance of the board. It dictates all the performance parameters and limitations of the board, such as memory size and speed, processor types and speeds, supported buses and their speeds, and more. If you plan to incorporate technologies such as the Accelerated Graphics Port (AGP) or the Universal Serial Bus (USB) into your system, you must ensure that your motherboard has a chipset that supports these features.

Because chipsets are constantly being introduced and improved over time, I can't list all of them and their functions; however, you will find a detailed description of many of them in Chapter 4. Several popular high-performance chipsets are on the market today. The best of these offer support for synchronous DRAM (SDRAM), double data rate SDRAM (DDR SDRAM), or Rambus DRAM (RDRAM) memory; PCI and AGP 4x or faster buses; Advanced Configuration and Power Interface (ACPI); and Ultra-DMA ATA (IDE) support.

◀◀ See "Chipsets," p. 232.

◀◀ See "Motherboard Selection Criteria (Knowing What to Look For)," p. 349.

Clearly, the selection of a chipset must be based largely on the processor you choose and the additional components you intend to install in the computer.

However, no matter which chipset you look for, I recommend checking for the following supported features:

- 133MHz or faster CPU bus support
- DDR SDRAM or RDRAM (main memory) support
- Error Correcting Code (ECC) memory support
- Advanced Configuration and Power Interface (ACPI) energy-saving functions
- AGP 4x or faster
- Dual Ultra-ATA/100 or Serial ATA interfaces
- USB 2.0 (high-speed USB) support

Most of the better chipsets on the market today should have these features and more. If you are intent on building the ultimate PC (at least by this week's standards), you also should consider the fastest processors available. Be sure not to waste your investment on the most capable processor by using a chipset that doesn't fully exploit its capabilities.

When you are designing your system, carefully consider the number and type of expansion cards you intend to install. Then, ensure that the motherboard you select has the correct number of slots and that they are of the correct bus type for your peripherals (ISA, PCI, and AGP). Because many newer boards don't have ISA slots, it might be time to get rid of any ISA boards you have and replace them with more capable PCI versions.

When you buy a motherboard, I highly recommend you contact the chipset manufacturer and obtain the documentation (usually called the *data book*) for your particular chipset. This explains how the memory and cache controllers, as well as many other devices in the system, operate. This documentation should also describe the Advanced Chipset Setup functions in your system's Setup program. With this information, you might be able to fine-tune the motherboard configuration by altering the chipset features. Because chipsets are frequently discontinued and replaced with newer models, don't wait too long to get the chipset documentation because most manufacturers make it available only for chips currently in production.

Note

One interesting fact about chipsets is that in the volume that the motherboard manufacturers purchase them, the chipsets usually cost about $40 each. If you have an older motherboard that needs repair, you usually can't purchase the chipsets because they aren't stocked by the manufacturer after they are discontinued. Not to mention that most chipsets feature surface mounting with ball grid array (BGA) packages that are extremely difficult to manually remove and replace. The low-cost chipset is one of the reasons motherboards have become disposable items that are rarely, if ever, repaired.

BIOS

Another important feature on the motherboard is the basic input/output system (BIOS). This is also called the ROM BIOS because the code is stored in a read-only memory (ROM) chip. There are several things to look for here. One is that the BIOS is supplied by one of the major BIOS manufacturers, such as AMI (American Megatrends International), Phoenix, Award, or Microid Research. Also, be sure that the BIOS is contained in a special type of reprogrammable chip called a Flash ROM or EEPROM (electrically erasable programmable read-only memory). This enables you to download BIOS updates from the manufacturer and, using a program it supplies, easily update the code in your BIOS. If you do not have the Flash ROM or EEPROM type, you must physically replace the chip if an update is required.

◀◀ See "Upgrading the BIOS," p. 373.

Virtually all motherboards built in the last few years include a BIOS with support for the Plug and Play (PnP) specification. This makes installing new cards, especially PnP cards, much easier. PnP automates the installation and uses special software built into the BIOS and the operating system (such as Windows 9x/Me and Windows 2000/XP) to automatically configure adapter cards and resolve adapter resource conflicts.

Note

For more information on PnP, see "Plug and Play BIOS" in Chapter 5, "BIOS." Also, an exhaustive listing of PnP device IDs can be found in the Technical Reference section of the DVD included with this book.

Memory

Older systems had L2 cache memory on the motherboard, but for almost all newer systems, this cache is now a part of the processor. The few remaining Socket 7 or Super7 motherboards do still include cache onboard, and it is normally soldered in and not removable or upgradable.

◀◀ See "Cache Memory: SRAM," p. 420.

Most Super7 motherboards support at least 1MB–2MB of cache memory.

For Pentium II/III/4, Celeron systems, and AMD's Athlon and Duron systems, no additional L2 memory is necessary because the processors have the cache memory integrated into the processor package, although some Athlon motherboards also have additional cache onboard, which is called L3.

Main memory typically is installed in the form of single inline memory modules (SIMMs), dual inline memory modules (DIMMs), or Rambus inline memory modules (RIMMs). Four physical types of main memory modules are used in PC systems today, with several variations of each. The four main types are as follows:

- 72-pin SIMMs (EDO RAM)
- 168-pin DIMMs (SDRAM)
- 184-pin DIMMs (DDR SDRAM)
- 184-pin or 232-pin RIMMs (RDRAM)

The 168-pin SDRAM DIMMs are common in lower-end systems today; however, just a few years ago, most systems came with 72-pin EDO SIMMs. Most systems use the DIMMs because they are 64 bits wide and can be used as a single bank on a Pentium or higher-class processor that has a 64-bit external data bus. Some of the newest and fastest systems using the Pentium 4 processor use the RDRAM RIMMs, which offer significant performance gains over standard SDRAM.

Double data rate (DDR) SDRAM memory is a new design of standard SDRAM in which data is transferred twice as quickly. DDR support is found in Athlon/Duron and Pentium 4/Celeron systems. Note that although both DDR SDRAM DIMMs and RDRAM RIMMs can use 184-pin connectors, their memory architectures are completely different and the memory is *not* interchangeable.

◀◀ See "Physical RAM Capacity and Organization," p. 449.

◀◀ See "DDR SDRAM," p. 430.

A 64-bit Pentium class system requires two 72-pin SIMMs (32 bits wide each) or a single 168-pin DIMM (64 bits wide) to make a single bank.

Memory modules can include an extra bit for each 8 for parity checking or ECC use. If ECC is important to you, be sure your chipset (and motherboard) supports ECC before purchasing the more expensive ECC modules.

◀◀ See "Parity and ECC," p. 457.

Another thing to watch out for is the type of metal on the memory module contacts, especially on motherboards using SIMMs. They are available with either tin- or gold-plated contacts. Although it might seem that gold-plated contacts are better (they are), you should not use them in all systems. You should instead always match the type of plating on the module contacts to what is also used on the socket contacts. In other words, if the motherboard SIMM, DIMM, or RIMM sockets have tin-plated contacts, you must use modules with tin-plated contacts. Most motherboards with SIMM sockets used tin-plated ones, requiring tin-plated SIMMs, whereas most DIMM and RIMM sockets are gold-plated, requiring gold-plated DIMMs and RIMMs.

If you mix dissimilar metals (tin with gold), corrosion on the tin side is rapidly accelerated and tiny electrical currents are generated. The combination of the corrosion and tiny currents causes havoc, and several types of memory problems and errors can occur. In some systems, I have observed that everything seems fine for about a year, during which the corrosion develops. After that, random

memory errors result. Removing and cleaning the memory module and socket contacts postpones the problem for another year, and then the problems return. How would you like this problem if you have 100 or more systems to support? Of course, you can avoid these problems if you insist on using SIMMs with contacts whose metal matches the metal found in the sockets in which they will be installed.

◀◀ See "Gold Versus Tin," p. 454.

For more information on PC memory of all types, see Chapter 6, "Memory."

I/O Ports

Most motherboards today have built-in I/O ports. If these ports are not built in, they must be supplied via a plug-in expansion board that, unfortunately, wastes an expansion slot. The following ports might be included in any new system you assemble:

- Keyboard connector (mini-DIN type)
- Mouse port (mini-DIN type)
- One or two serial ports (16550A buffered UART type)
- Parallel port (EPP/ECP type)
- Four or more USB ports
- Optional display connector (integrated video)
- Optional audio/game connectors (MIDI/joystick, speaker, and microphone)
- Two local bus enhanced IDE ports (primary and secondary); UDMA 66 or faster preferred
- Floppy controller

Some motherboards lack the serial, parallel, keyboard, and mouse ports (referred to as legacy ports), instead relying on USB for those connections. You might want to avoid "legacy-free" motherboards if you still use peripherals with those types of connections. Many motherboards feature the optional integrated video and sound interfaces, especially micro-ATX motherboards.

All the integrated ports are supported either directly by the motherboard chipset or by an additional Super I/O chip and additional interface components. Adding the optional video and sound interfaces directly to the motherboard saves both money and the use of an expansion slot, especially important in the less expensive systems sold today.

If these devices are not present on the motherboard, various Super I/O or multi-I/O boards that implement all these ports are available. Again, most of the newer versions of these boards use a single-chip implementation because it is cheaper and more reliable.

◀◀ See "Super I/O Chips," p. 290.

It has become an increasingly popular practice in recent years (especially in Slimline-style systems) to integrate other standard computer functions into the motherboard design, such as video, sound, and even network adapters. The advantages of this practice include freeing up expansion slots that would normally be occupied by separate adapter cards and saving money. The price difference between a motherboard with integrated video and sound and one without would be far less than the cost of good-quality sound and video cards.

The drawback, of course, is that you have little or no choice about the features or quality of the integrated adapters. Integrated components such as these are nearly always of serviceable quality, but they certainly do not push the performance envelope of higher-end expansion cards. Most people who

decide to build a system themselves do so because they want optimum performance from every component, which you do not get from integrated video and sound.

Buying a motherboard with integrated adapters, however, does not preclude you from adding expansion devices of the same type. You usually can install a video or sound card into a system with an integrated sound adapter without major problems, except that the additional cost of the integrated component is wasted. You also might encounter difficulties with the automated hardware detection routines in operating systems such as Windows 9x/Me/2000/XP detecting the wrong adapter in your system, but you can remedy this by manually identifying the expansion card to the OS.

If four or more USB ports exist, they often are split among two buses, with one set of connections on the back of the board and another set as a pin-header connector on the motherboard. A cable then plugs into this connector, enabling you to route the second USB bus port to the front of the PC case. Most newer cases have provisions for front-mounted USB ports in this manner, which makes temporarily connecting devices such as digital cameras or MP3 players for transferring files easier.

Note that if your motherboard has integrated devices such as video and sound, you must go into the BIOS Setup to disable these devices if you want to add a card-based replacement device. Check your BIOS Setup menus for an Enable/Disable setting for any integrated devices.

A trend with some newer low-cost systems is the complete elimination of the Super I/O chip and all the integrated ports contained within. These are called legacy-free PCs and lack any serial ports, parallel ports, and standard keyboard and mouse connections. All external expansion must be done via the USB ports. This means your keyboard, mouse, printer, external modem, and so on must be of the USB type.

Floppy Disk and Removable Drives

Since the advent of the CD-RW, the floppy disk drive has largely been relegated to a minor role as an alternative system boot device. Usually, today's systems are equipped with a 1.44MB 3 1/2" drive. All systems today are capable of booting from CD, making CD-R (or especially CD-RW discs) a useful high-capacity replacement for floppy or Zip drives.

For additional removable storage, I recommend a CD-RW (CD-rewritable) drive over the Zip or even LS-120 formats. These are now relatively inexpensive, and the media is low priced as well. A CD-RW drive can also write on even more inexpensive CD-R media. This provides an easy way to back up or archive up to 700MB of data (74-minute CDs hold 682MB, whereas 80-minute CDs hold 737MB).

Hard Disk Drives

Your system also needs at least one hard disk drive. In most cases, a drive with a minimum capacity of 20GB is recommended, although in some cases you can get away with less for a low-end configuration. High-end systems should have drives of 40GB or higher. One of the cardinal rules of computer shopping is that you can never have too much storage. Buy as much as you can afford, and you'll almost certainly end up filling it anyway.

Tip

If you are an Internet user, one informal method of estimating how much disk space you will need is to go by the speed of your Internet connection. If you have a high-speed link, such as that provided by a DSL connection, a cable modem, or a LAN, you will find that the ease of downloading large amounts of data fills disk drives amazingly quickly. I would recommend at least a 40GB hard drive in these cases. In addition, a removable storage system with a large capacity, such as a CD-RW drive, is also a good idea.

Note that Windows 95 does not support any drives larger than 32GB. You should upgrade to Windows 98, Windows Me, Windows 2000, or Windows XP before installing a hard drive larger than 32GB.

The most popular hard drive interface for desktop systems is ATA (IDE), although SCSI is preferable for use with multitasking OSes. ATA generally offers greater performance for single-drive installations, but SCSI is better for use with two or more drives or with multitasking operating systems, such as Windows 95/98/Me and NT/2000/XP. This is because of the greater intelligence in the SCSI interface, which removes some of the I/O processing burden from the system's CPU. This is especially important if you are using Windows NT or Windows 2000 in a server role, where it supports multiple users and much heavier file access. The SCSI interface is also more versatile than ATA; it can handle either 7 or 15 devices, including scanners, tape drives, optical drives, hard drives, and removable-media drives.

Some of the newest motherboards now feature RAID-compatible ATA interfaces. These enable you to install two identical IDE drives (a pair of 30GB drives, for example) and treat them as a single very large and very fast 60GB hard drive.

◀◀ See "ATA RAID," p. 534.

Note

In most cases, a system's ATA adapter is integrated into the motherboard. With SCSI, this is much less common. Although you sometimes can purchase a motherboard with an integrated SCSI adapter, you are more likely to have to purchase a separate SCSI host adapter and install it into one of your system's expansion slots. It is recommended that you select an SCSI adapter that uses the fastest expansion bus your system supports, which in most cases today is PCI. Good-quality SCSI host adapters are considerably more complex than are ATA adapters and are therefore more expensive. Be sure to consider this additional expense and the need for an additional slot when deciding on a hard drive interface for your system.

◀◀ See "How to Reliably Record CDs," p. 788.

◀◀ See "SCSI Versus IDE," p. 565.

Several brands of high-quality hard disk drives are available from which to choose, and most offer similar performance within their price and capacity categories. In fact, you might notice that the capacities and specifications of the various ATA and SCSI drives certain manufacturers offer are remarkably similar. This is because a single drive assembly is manufactured for use with both interfaces. The same ATA drive, for example, with the addition of a SCSI interface chip on the logic board, becomes a SCSI drive, often at a substantially higher price.

Serial ATA is rapidly replacing the standard parallel ATA in newer systems, so that is something you might want to look for as well. See Chapter 7, "The IDE Interface," to learn more about Serial ATA.

Optical Drives

An optical drive should be considered a mandatory item in any PC you construct these days. This is because virtually all software is now distributed on CD-ROM, and many newer titles are on DVD. DVD drives can read CD-ROMs as well as DVD-ROMs, so they are more flexible. Systems can now even boot from CD-ROM drives as long as the system BIOS provides the proper support.

DVD-ROM is a high-density data storage format that uses a CD-size disc to store a great deal more data than a CD-ROM—from 4.7GB to 17GB, depending on the format. These drives can read standard CD-ROMs and audio CDs, as well as the higher-capacity DVD data and video discs.

◀◀ See "DVD," p. 748.

Several types of CD-ROM or DVD drives are available these days, but I generally recommend a minimum of a 32x CD-ROM or an 8x DVD-ROM drive connected using the integrated ATA interface found on all modern motherboards. This results in the best possible performance with the minimum amount of hassle. If you plan on using SCSI for your hard drives, however, you might want to select a SCSI CD-ROM or DVD-ROM drive; you'll improve your multitasking performance.

You also might consider purchasing a rewritable CD-ROM drive, generally known as a CD-RW drive (as discussed in the following). If you do, I recommend you get this in addition to your existing CD-ROM or DVD-ROM drive—that way you easily can copy existing data and music CDs. This is also a good idea because the recordable drives are typically slower than the ROM-only versions. Another reason to install both a CD-RW and a CD-ROM/DVD drive is to enable the easy backup of an existing CD-ROM without copying the contents to the hard drive first.

Burning your own CDs can be a convenient and relatively inexpensive data storage method. Drives advertised as CD-RW handle both CD-RW (rewritable) and CD-R (record once) media. Note, though, that many older CD-ROM drives can't read CD-RW media (drives labeled as MultiRead can read CD-RW media), whereas virtually all drives can read CD-R discs.

Tip

For the highest reliability when using CD-RW drives, be sure your drive incorporates one of the forms of buffer underrun protection, such as BURN-proof, JustLink, or Waste-Proof. This prevents you from making coasters (unusable discs) when burning CDs.

Input Devices

Obviously, your system needs a keyboard and some type of pointing device, such as a mouse. Different people prefer different types of keyboards, and the "feel" of one type can vary considerably from other types. If possible, I suggest you try a variety of keyboards until you find the type that suits you best. I prefer a stiff action with tactile feedback myself, but others prefer a lighter, quieter touch.

Because two types of keyboard connectors are found in systems today, be sure that the keyboard you purchase matches the connector on your motherboard. The original 5-pin DIN and newer 6-pin mini-DIN keyboard connectors are electrically compatible, enabling you to adapt either type of keyboard connector to either type of keyboard. The newest keyboard interface is USB, driven by the widespread availability of the USB connector and the rise of legacy-free PCs that have only USB ports.

As with any USB device, you must have support in the operating system for USB, and in the case of USB keyboards, your system BIOS must support a function called Legacy USB or USB Keyboard and Mouse if you want to use the USB keyboard outside the Windows graphical user interface. Most recent BIOSes have this feature. However, to enable you to use your USB keyboard on both new and older systems, I recommend you look for a model that also supports the traditional keyboard ports.

◀◀ See "Keyboards," p. 996.

◀◀ See "Keyboard Technology," p. 1004.

The same selection concept also applies to mice or other pointing devices; a number of choices are available that suit different individuals. Try several before deciding on the type you want. If your motherboard includes a built-in mouse port, be sure you get a mouse designed for that interface. This mouse is often called a PS/2 type mouse because the IBM PS/2 systems introduced this type of mouse port. Many older systems use a serial mouse connected to a serial port, but a motherboard-integrated

mouse port is preferable because it leaves both serial ports free for other devices. Some USB mice work with the PS/2 port, but others are made strictly for the USB port. I recommend dual-mode mice that work with either type of system. In addition, you can even choose from cordless versions.

Tip

You might be tempted to skimp on your keyboard and mouse to save a few dollars. Don't! You do all your interacting with your new PC through these devices, and cheap ones make their presence known every time you use your system. I insist on high-quality mechanical switch–type keyboards on all my systems.

The Universal Serial Bus (USB) promises to render the standard I/O ports on the PC obsolete. Essentially, USB brings PnP support to external peripherals by enabling you to plug up to 127 devices into a single port supporting data transfer rates up to 60MB/sec. Typically, you plug a USB hub into a port integrated into the motherboard and then plug other devices into that. Virtually all current motherboards support USB.

◀◀ See "USB and IEEE-1394 (i.Link or FireWire)," p. 962.

There are virtually no limits to the types of devices available for USB. Modems, keyboards, mice, CD-ROM drives, speakers, joysticks, tape and floppy drives, scanners, cameras, MP3 players, and printers are just some of the devices available. However, before you start buying all USB peripherals for your new system, be aware that performance problems can occur with some devices if used on a single bus, and sometimes compatibility problems can occur as well. USB 2.0 (also called high-speed USB) solves these problems, so you should be sure that any new systems you buy or build include USB 2.0 ports.

◀◀ See "USB Keyboards," p. 1001.

Video Card and Display

You need a video adapter and a monitor or display to complete your system. Numerous choices are available in this area, but the most important piece of advice I have to give is to choose a good monitor. The display is your main interface to the system and can be the cause of many hours of either pain or pleasure, depending on which monitor you choose.

I usually recommend a minimum of a 17" display these days. Anything smaller can't acceptably display a 1,024×768 pixel resolution. If you opt for a 15" or smaller display, you might find that the maximum tolerable resolution is 800×600. This might be confusing because many 15" monitors are capable of displaying 1,024×768 resolution or even higher, but the characters and features are so small onscreen at that resolution that excessive eyestrain and headaches are often the result; the display often is blurry when a monitor is run at its maximum resolution. If you spend a lot of time in front of your system and want to work in the higher screen resolutions, a 17" display should be considered mandatory. If you can afford it, I recommend a 19" display; they work even better at the higher resolutions and have come down in price considerably from previous years. Look for CRT displays with lower dot-pitch (0.28dpi or less), which indicates the size and spacing of dots in the CRT mask. Lower means higher resolution and a clearer picture.

If your desk space is limited and you can afford it, consider the wide variety of flat-screen LCD panels now available (a 15" LCD panel is about equal in viewable area to a 17" CRT). In most cases, they attach to the normal VGA analog port, but the most current models work with the DVI connector available on some of the newest video cards. LCD panels are an excellent choice if you always use the native resolution (typically 1024×768), but if you need to change resolutions (for previewing Web page designs or game playing), CRTs are better.

Your video card and monitor should be compatible in terms of refresh rate. The minimum refresh rate for a solid, nonflickering display is 70Hz–72Hz (the higher, the better). If your new video card can display 16 million colors at a resolution of 1,024×768 and a refresh rate of 76Hz, but your monitor's maximum refresh rate at 1,024×768 is 56Hz, you can't use the video card to its maximum potential. Configuring a video adapter to deliver signals the monitor can't support is one of the few software configuration processes that can physically damage the system hardware. Pushing a monitor beyond its capabilities can cause it irreparable harm.

Video adapters in recent years have become standardized on the accelerated graphics port (AGP) interface, although many older systems used PCI-based video cards. You might need to use a PCI video card if you are adding a secondary video adapter to your system to run a second monitor. Windows 98, Me, and 2000 support this feature, and it can be very useful for some applications. To save a slot in your system, you can also use a dual-display card in your AGP slot, although their 3D performance isn't as high as the best 3D accelerators now on the market.

If you are into gaming, you will want one of the high-performance 3D video cards currently available. Modern games are very video-intensive, so be sure to check with the game software companies as to which cards they recommend. Although early 3D cards connected to the standard 2D graphics card, this design is now obsolete. High-performance 3D cards from NVIDIA and ATI provide both fast 2D graphics and excellent 3D performance.

◀◀ See "Accelerated Graphics Port," p. 322.

◀◀ See "3D Graphics Accelerators," p. 896.

If you are adding a video card to a newly constructed system, the video card should be inserted into the AGP slot. Most current motherboards support AGP 4x, AGP Pro, or AGP 8x.

If you are installing a newer AGP video card as an upgrade to your current system, you can remove the current video card and replace it with any video card that supports the motherboard's AGP standard. You can also replace an existing PCI video card with another PCI video card if there is no AGP slot, but you should consider a motherboard upgrade instead to provide an AGP slot for faster video.

Many motherboards with onboard video still have an AGP slot; if your motherboard has one, you can insert an AGP card into this slot. The onboard video should be automatically disabled in most cases. If the motherboard has only PCI slots, you might want to consider upgrading to a motherboard that has an AGP slot instead.

If you are replacing an existing video card, be sure to check the chipset on the video card against the list of video card chipsets provided in the section "3D Chipsets" in Chapter 15, "Video Hardware." You should avoid chipsets marked as OLD if you are looking for acceptable performance and support for the latest versions of Windows.

Sound Card and Speakers

You need a sound card and a set of external speakers for any system that you want to be multimedia capable. Although the sound card should be compatible with the Creative Labs Sound Blaster cards, which set the early standards for DOS audio, it is now more important to purchase a sound card that is compatible with Windows-based sound APIs, such as DirectX. For best performance, I recommend you get a PCI-based sound card instead of an older ISA bus design. There can be some problems with support for older DOS-based games with some of the new cards, but most of these issues have been addressed by special drivers for the newer cards.

Speakers designed for use with PCs range from tiny, underpowered devices to large audiophile systems. Many of the top manufacturers of stereo speakers now produce speaker systems for PCs. Some include subwoofers or even a full Dolby 5.1 surround sound implementation.

Accessories

Apart from the major components, you need several other accessories to complete your system. These are the small parts that can make the assembly process a pleasure or a chore. If you are purchasing your system components from mail-order sources, you should make a complete list of all the parts you need, right down to the last cable and screw, and be sure you have everything before you begin the assembly process. It is excruciating to have to wait several days with a half-assembled system for the delivery of a forgotten part.

Heatsinks/Cooling Fans

Most of today's faster processors produce a lot of heat, and this heat has to be dissipated so your system doesn't operate intermittently or even fail completely. Heatsinks are available in two main types: passive and active.

Passive heatsinks are simply finned chunks of metal (usually aluminum) that are clipped or glued to the top of the processor. They act as a radiator and, in effect, give the processor more surface area to dissipate the heat. *Active* heatsinks are required by many processors today because of their higher capacity and smaller space requirements. Often you have no control over which heatsink you use because it comes already attached to the processor. If you have to attach it yourself, you should use a thermal transfer grease or sticky tape to fill any air gaps between the heatsink and the processor. This allows for maximum heat transfer and the best efficiency.

An active heatsink includes a built-in fan. These can offer greater cooling capacity than the passive types, and some processors—especially "boxed" processors from Intel and AMD—are sold with the heatsink and fan included. OEM processors don't include a heatsink from the processor manufacturer, but most vendors who sell them add an aftermarket heatsink and fan to the package. Note that all modern heatsinks require a thermal interface material (usually grease or paste) be applied to the base of the heatsink before installation.

Note

The ATX form factor motherboards and chassis are designed to improve system cooling. These systems move the processor and memory near the power supply for better cooling. They often feature secondary case-mounted cooling fans for extra insurance. Note that many processors today come with the heatsink integrated as a part of the unit, often an active type with a high-quality ball-bearing cooling fan built in.

Another consideration for cooling is with the case. The fan in the power supply and optionally one on the CPU heatsink often are not enough for a modern high-performance system. I recommend you get a case that includes at least one additional cooling fan. This is typically mounted in the front of the chassis, taking air in from the front and directing it over the motherboard; it often is hidden behind the card support slots used for full-length expansion cards. Some cases include extra fans near the drive bays for cooling the drives as well.

If you are upgrading an existing system, several companies make fan assemblies that insert into a drive bay for additional cooling. They take the place of a 5 1/4" drive and take air in through the front bezel, directing it back into the case. Bay-mounted fans are an especially good idea if you are using the 10,000rpm or faster SCSI drives on the market because they run extremely hot. There are even fan assemblies mounted on cards that blow air out the rear of the case. Keep in mind that it is best to keep the interior of the PC below 100°F; anything over 110° dramatically reduces component life and leads to stability problems.

Cables

PC systems need many different cables to hook up everything. These can include power cables or adapters, disk drive cables, internal or external CD-ROM cables, and many others. Frequently, the motherboard includes the cables for any of the internal ports, such as floppy or hard drives. Other external devices you purchase come with included cables, but in some cases, they aren't supplied. The Vendor List on the DVD contains contact information for several cable and small parts suppliers that can get you the cables or other parts you need to complete your system.

Another advantage of the ATX motherboard form factor is that these boards feature externally accessible I/O connectors directly mounted to the rear of the board. This eliminates the rat's nest of cables found in the common Baby-AT form factor systems and also makes the ATX system a little cheaper and more reliable.

If you build your system using all OEM (what the industry calls *white box*) components, be aware that these sometimes don't include the accessories, such as cables and additional documentation, that you would get with a boxed-retail version of the same component.

Hardware

You will need screws, standoffs, mounting rails (if your case requires them), and other miscellaneous hardware to assemble your system. Most of these parts are included with the case or your other system components. This is especially true of any card or disk drive brackets or screws. When you purchase a component such as a hard drive, some vendors offer you the option of purchasing the bare drive or a kit containing the required cables and mounting hardware for the device. Most of the time bare drives don't include any additional hardware, but you might not need it anyway if the mounting hardware comes with your case. Even so, spending the few additional dollars for the complete drive kit is rarely a waste of money. Even if you're left with some extra bits and pieces after assembling your system, they will probably come in handy someday.

In situations in which you need other hardware not included with your system components, you can consult the Vendor List for suppliers of small parts and hardware necessary to get your system operational.

Hardware and Software Resources

When you are planning to build a system, it is important to consider how all your selected components will work together and how the software you run must support them. It is not enough to be sure that you have sufficient slots on the motherboard for all your expansion cards and enough bays in the case for all your drives. You must also consider the resources required for all the components.

If you are planning to use ISA cards, for example, you need to know whether your new motherboard has any ISA slots and whether it has enough slots for your cards. Interrupt (IRQ) conflicts used to be a major problem, but if you use Windows 95 OSR 2.x (95B/95C) or newer versions with any recent chipset and have PCI cards, IRQ routing and sharing minimizes this concern. You should still be aware of IRQ use if you will be installing one or more ISA cards in your system because ISA cards can't share IRQs. Essentially, you should completely configure the system before you begin ordering any parts. Planning a system to this level of detail can be a lot of work, which is one reason the vast majority of PCs are prebuilt.

Another consideration is the operating system and other software you will need. Prebuilt systems nearly always arrive with the operating system installed, but when you build your own, you must be prepared with a copy of your selected operating system—including a system disk so you can boot the system the first time. Because nearly any operating system in use today is distributed on CD-ROM,

you must get your computer to recognize the CD-ROM drive before you can install an operating system. To make this process simpler, you should create a bootable CD. Note that the OEM versions of Windows 98 and later are bootable, but the retail upgrade versions aren't.

◀◀ See "Making a Bootable CD for Emergencies," p. 807.

The operating system you select for your new computer is another important decision. You must be certain that the OS supports all the hardware you've selected, which can occasionally be a difficult task. For example, you will need Windows 98 or later to properly support USB devices in your system.

Windows 98 and later come on bootable CD-ROMs if you get what is called the OEM version of the operating system. The so-called retail or upgrade editions often are restricted, aren't bootable, and might also search for preexisting files or operating systems before they will load. Because Microsoft doesn't allow OEM versions of its operating systems to be sold separately, be sure you get an OEM edition of whatever operating system you will be running with your motherboard or hard disk. The terms of the Microsoft dealer (or system builder) agreement allow dealers to sell the OS only with a PC, and the terms of the agreement state that a motherboard or hard disk qualifies as enough of a PC to allow an operating system bundle. No matter what, be sure you get the original OEM version on CD-ROM.

Tip

If you don't have the OEM version of your OS, or the system you are assembling does not support booting from CD (called El Torito support after the Phoenix-created standard), you must create a boot floppy with CD-ROM drivers. Windows 98 and later include a disk with a set of universal CD-ROM drivers that work for most systems; for Windows 95 and older operating systems, you must either borrow a Windows 98 or later startup disk or create your own bootable floppy with the correct drivers.

I'll cover this in more detail when we get to the OS load section of the building process.

Drivers for specific hardware components might also be a problem. It is a good idea to gather all the latest driver revisions for your hardware, as well as BIOS flashes, firmware updates, and other software components, and have them available when you begin the assembly process. Floppy disks are preferable for this because your CD-ROM drive and connectivity hardware might not yet be operative.

System Assembly and Disassembly

Actually assembling the system is easy after you have lined up all the components. In fact, you will find the parts procurement phase the most lengthy and trying of the entire experience. Completing the system is basically a matter of screwing everything together, plugging in all the cables and connectors, and configuring everything to operate properly together.

In short order, you will find out whether your system operates as you had planned or whether some incompatibilities exist between some of the components. Be careful and pay attention to how you install all your components. It is rare that a newly assembled system operates perfectly the first time, even for people who are somewhat experienced. It is very easy to forget a jumper, switch, or cable connection that later causes problems in system operation. Most people's first reaction when problems occur is to blame defective hardware, but that is usually not the source. Usually, the problem can be traced to some missed step or error made in the assembly process.

Above all, the most crucial rule of assembling your own system is to save every piece of documentation and software that comes with every component in your system. This material can be indispensable in troubleshooting problems you encounter during the assembly process or later. You should also

retain all the packing materials used to ship mail-order components to you until you are certain they will not have to be returned.

Assembly Preparation

The process of physically assembling a PC requires only a few basic tools: a 1/4" nut driver or Phillips-head screwdriver for the external screws that hold the cover in place and a 3/16" nut driver or Phillips-head screwdriver for all the other screws. Needle-nose pliers can also help in removing motherboard standoffs, jumpers, and stubborn cable connectors. Because of marketplace standardization, only a couple types and sizes of screws (with a few exceptions) are used to hold a system together. Also, the physical arrangement of the major components is similar even among different manufacturers. Figure 22.1 shows the components that go into a typical system, and Figure 22.2 shows the system with those components assembled. Note that the components shown here are for a standard PC. Your final component list might vary.

You'll find more information on tools used to work on PCs in Chapter 23, "PC Diagnostics, Testing, and Maintenance."

Other tools you'll need are software related. You'll need the master operating system CD-ROM, and if your particular CD-ROM version isn't bootable or your system is older and doesn't support booting from CD, you'll also need an operating system startup floppy disk with CD-ROM drivers installed. This way, your system will recognize the CD-ROM drive and enable you to install the operating system from it. Newer operating systems often come on bootable CDs, but normally only the OEM (and not retail) versions of the OS are configured that way.

The Windows 98 and later versions' startup floppies include generic ATAPI and SCSI CD-ROM drivers on them, enabling virtually all CD-ROMs to be recognized after booting from them. If you are installing Windows 95 or some other operating system that does not include a startup disk with CD-ROM drivers already installed, you can either use a Win98 or later startup disk or take your existing startup disk and install the CD-ROM drivers that came with your drive. That procedure is covered later in this chapter.

The following sections cover the assembly and disassembly procedure:

- Case or cover assembly
- Power supply
- Adapter boards
- Motherboard
- Disk drives

Later, you learn how to install and remove these components for several types of systems. With regard to assembly and disassembly, it is best to consider each system by the type of case it uses. All systems that have AT-type cases, for example, are assembled and disassembled in much the same manner. Tower cases are basically AT-type cases turned sideways, so the same basic instructions apply. Most Slimline and XT-style cases are similar; these systems are assembled and disassembled in much the same way.

The following section lists assembly and disassembly instructions for several case types.

ESD Protection

One issue you must be aware of is electrostatic discharge (ESD) protection. Another is recording the configuration of the system with regard to the physical aspects of the system (such as jumper or switch settings and cable orientations) and the logical configuration of the system (especially in terms of elements such as CMOS settings).

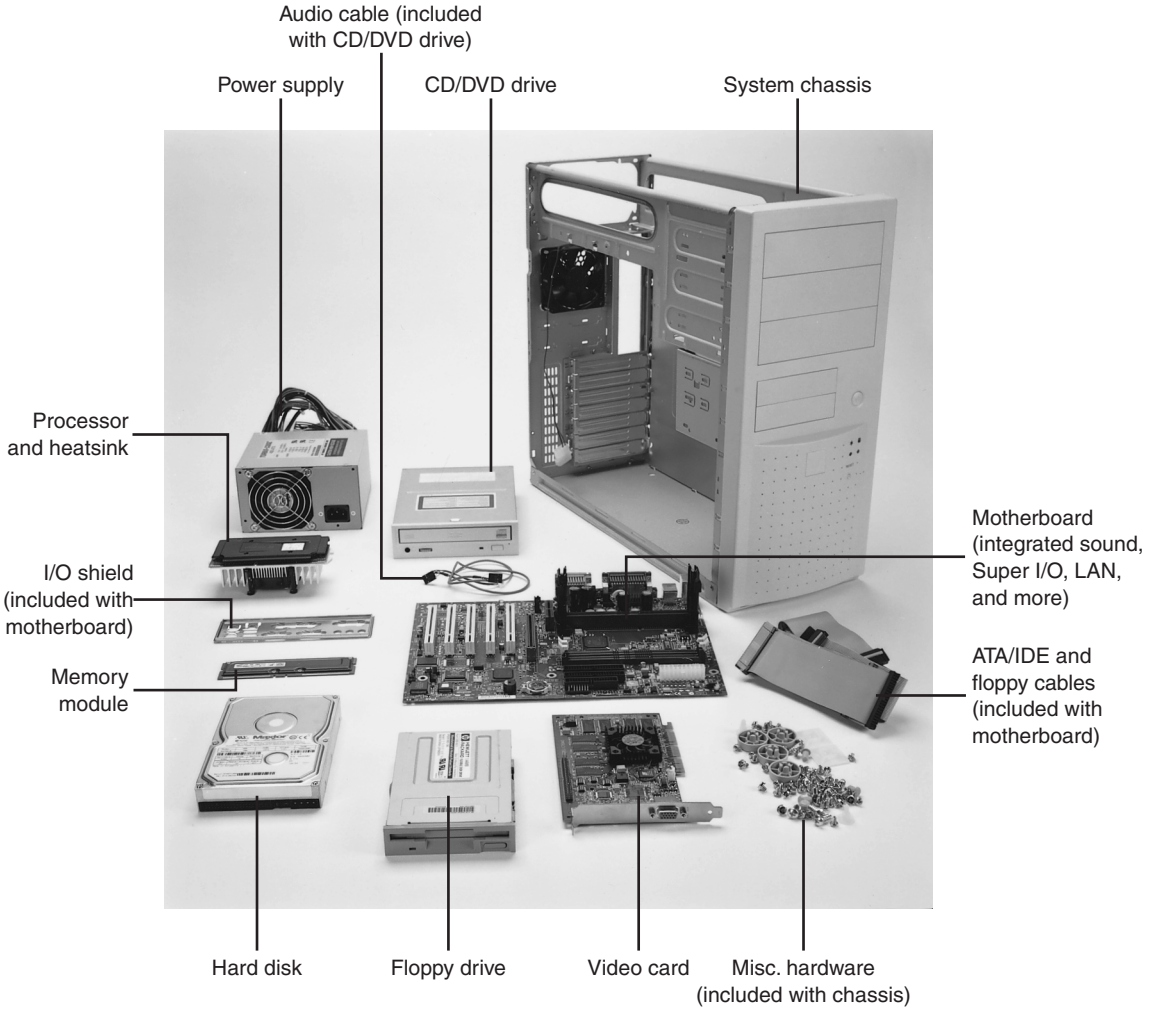


Figure 22.1 Components used in building a typical PC. *Case and power supply courtesy of PC Power & Cooling, Inc. Motherboard and processor courtesy of Intel Corporation. Other components supplied by Micro X-Press (www.microx-press.com) and Creative Labs, Inc.*

When you are working on the internal components of a computer, you must take the necessary precautions to prevent accidental static discharges to the components. At any time, your body can hold a large static voltage charge that can easily damage components of your system. Before I ever put my hands into an open system, I first touch a grounded portion of the chassis, such as the power supply case. This action serves to equalize the electrical charges the device and my body might be carrying. Be sure the power supply is unplugged during all phases of the assembly process. Some will claim that you should leave the system plugged in to provide an earth ground through the power cord and outlet, but that is unnecessary. If you leave the system plugged in, you open yourself up to other problems, such as accidentally turning it on or leaving it on when installing a board or device, which can damage the motherboard or other devices.

Figure 22.2 The completed system using all components shown in Figure 22.1. *Case and power supply courtesy of PC Power & Cooling, Inc. Motherboard and processor courtesy of Intel Corporation. Other components supplied by Micro X-Press (www.microx-press.com).*

Caution

Also note that ATX power supplies used in many systems today deliver a +5v current to the motherboard continuously—that is, whenever they are plugged in. Bottom line: Be sure any system you are working on is completely unplugged from the wall outlet.

High-end workbenches at repair facilities have the entire bench grounded, so it's not as big of a problem; however, you need something to be a good ground source to prevent a current from building up in you.

A more sophisticated way to equalize the charges between you and any of the system components is to use an ESD protection kit. These kits consist of a wrist strap and mat, with ground wires for attachment to the system chassis. When you are going to work on a system, you place the mat next to or partially below the system unit. Next, you clip the ground wire to both the mat and the system's chassis, tying the grounds together. You then put on the wrist strap and attach that wire to a ground. Because the mat and system chassis are already wired together, you can attach the wrist-strap wire to the system chassis or to the mat. If you are using a wrist strap without a mat, clip the wrist-strap wire to the system chassis. When clipping these wires to the chassis, be sure to use an area that is free of paint so a good ground contact can be achieved. This setup ensures that any electrical charges are

carried equally by you and any of the components in the system, preventing the sudden flow of static electricity that can damage the circuits.

As you install or remove disk drives; adapter cards; and especially delicate items such as the entire motherboard, SIMMs, or processors, you should place these components on the static mat. Sometimes people put the system unit on top of the mat, but the unit should be alongside the mat so you have room to lay out all the components as you work with them. If you are going to remove the motherboard from a system, be sure you leave enough room for it on the mat.

If you do not have such a mat, place the removed circuits and devices on a clean desk or table. Always pick up a loose adapter card by the metal bracket used to secure the card to the system. This bracket is tied into the ground circuitry of the card, so by touching the bracket first, you prevent a discharge from damaging the components of the card. If the circuit board has no metal bracket (a motherboard, for example), handle the board carefully by the edges, and try not to touch any of the connectors or components. If you don't have proper ESD equipment such as a wrist strap or mat, be sure to periodically touch the chassis while working inside the system to equalize any charge you might have built up.

Caution

Some people recommend placing loose circuit boards and chips on sheets of aluminum foil. I absolutely *do not recommend* this procedure because it can actually result in an explosion! Many motherboards, adapter cards, and other circuit boards today have built-in lithium or NiCad batteries. These batteries react violently when they are shorted out, which is exactly what you would be doing by placing such a board on a piece of aluminum foil. The batteries will quickly overheat and possibly explode like a large firecracker (with dangerous shrapnel). Because you will not always be able to tell whether a board has a battery built into it somewhere, the safest practice is to never place any board on any conductive metal surface.

Recording Physical Configuration

While you are assembling a system, you should record all the physical settings and configurations of each component, including jumper and switch settings, cable orientations and placement, ground wire locations, and even adapter board placement. Keep a notebook handy for recording these items, and write down all the settings. See Chapter 4 for more information on motherboard connector, jumper, and other component locations. Figure 22.3 shows a typical motherboard jumper.

It is especially important to record all the jumper and switch settings on the motherboard, as well as those on any card you install in the system (cards seldom use jumpers or switches today, but many motherboards still do). If you accidentally disturb these jumpers or switches, you will know how they were originally set. This knowledge is very important if you do not have all the documentation for the system handy. Even if you do, undocumented jumpers and switches often do not appear in the manuals but must be set a certain way for the item to function. Also, record all cable orientations. Most name-brand systems use cables and connectors that are keyed so that they can't be plugged in backward, but some generic PCs do not have this added feature. In addition, you can mix up hard disk and floppy cables. You should mark or record what each cable was plugged into and its proper orientation. Ribbon cables usually have an odd-colored (red, green, blue, or black) wire at one end that indicates pin 1. There might also be a mark on the connector, such as a triangle or even the number 1. The devices the cables are plugged into are also marked in some way to indicate the orientation of pin 1. Often, a dot appears next to the pin 1 side of the connector, or a 1 or other mark might appear.

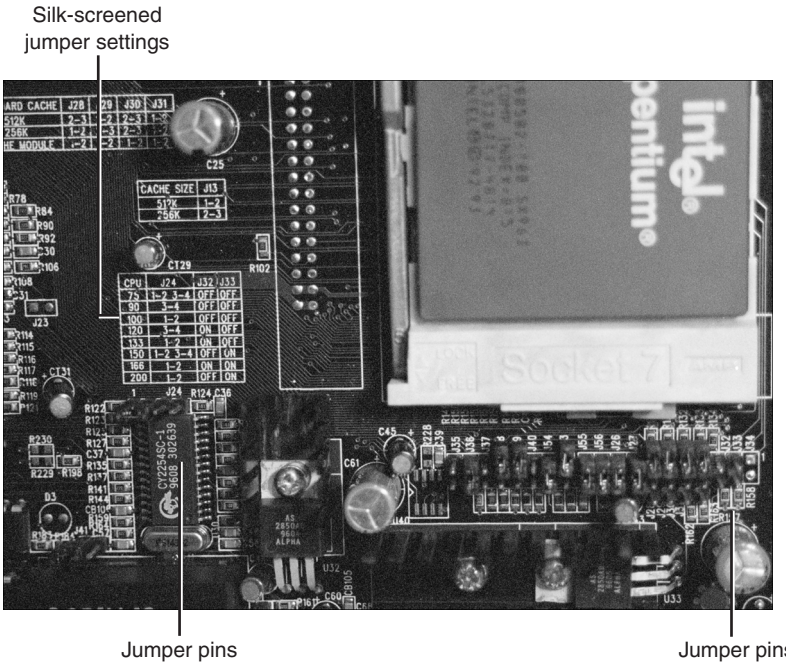

Figure 22.3 Motherboard jumpers often are silk-screened on the motherboard, as shown here; the jumper position shown here is used to configure the motherboard for a Pentium processor.

Although cable orientation and placement seem to be very simple, we rarely get through the entire course of my PC troubleshooting seminars without at least one group of people having cable-connection problems. Fortunately, in most cases (except power cables), plugging any of the ribbon cables inside the system backward doesn't cause any permanent damage.

Power and battery connections on pre-ATX systems are exceptions; plugging them in backward in most cases causes damage. In fact, plugging the motherboard power connectors in backward or in the wrong plug location puts 12v where only 5v should be—a situation that can cause components of the board to violently explode. I know of several people who have facial scars caused by shrapnel from components that exploded because of improper power supply connections! As a precaution, I always turn my face away from the system when I power it on for the first time. If you are using an ATX board and power supply, there is little chance of this happening because of the superior type of power connector used *unless* you mix a September 1998 or newer Dell power supply or motherboard with a standard motherboard or power supply.

Plugging in the CMOS battery backward can damage the CMOS chip, which usually is soldered into the motherboard; in such a case, the motherboard must be replaced.

Finally, you should record miscellaneous items such as the placement of any ground wires, adapter cards, and anything else that you might have difficulty remembering later. Some configurations and setups might be particular about the slots in which the adapter cards are located, so you should put everything back exactly the way it was originally.

Motherboard Installation

When you are installing your system's motherboard, unpack the motherboard and check to ensure you have everything that should be included. If you purchase a new board, you typically get at least the motherboard, some I/O cables, and a manual. If you order the motherboard with a processor or memory, it is usually installed on the board for you but might also be included separately. Some board kits include an antistatic wrist strap to help prevent damage due to static electricity when installing the board.

Installing the CPU and Heatsink

Before your new motherboard is installed, you should install the processor and memory. This usually is much easier to do before the board is installed in the chassis. Some motherboards have jumpers that control both the CPU speed and the voltage supplied to it. If these are set incorrectly, the system might not operate at all, might operate erratically, or might possibly even damage the CPU. If you have any questions about the proper settings, contact the vendor who sold you the board before making any jumper changes.

◀◀ See "CPU Operating Voltages," p. 105.

Most processors today run hot enough to require some form of heatsink to dissipate heat from the processor. To install the processor and heatsink, use the following procedure:

1. Take the new motherboard out of the antistatic bag it was supplied in and set it on the bag or the antistatic mat, if you have one.
2. Install the processor. There are two procedures—one for socketed processors and the other for slot-based processors. Follow the appropriate instructions for the type you are installing:
   - *For socketed processors, the procedure is as follows:* Find pin 1 on the processor; it usually is denoted by a corner of the chip that is marked by a dot or bevel. Next, find the corresponding pin 1 of the ZIF socket for the CPU on the motherboard; it also is usually marked on the board or with a bevel in one corner of the socket. Be sure the pins on the processor are straight and not bent; if they are bent, the chip won't insert properly into the socket. If necessary, use small needle-nose pliers or a hemostat to carefully straighten any pins. Don't bend them too much—they might break off, ruining the chip. Insert the CPU into the ZIF socket by lifting the release lever until it is vertical. Then, align the pins on the processor with the holes in the socket and drop it down into place. If the processor does not seem to want to drop in all the way, remove it to check for proper alignment and any possibly bent pins. When the processor is fully seated in the socket, push the locking lever on the socket down until it latches to secure the processor (see Figure 22.4).
   - *For slot-based processors, the procedure is different.* You need the processor, the universal retention mechanism brackets with included fasteners, and the heatsink supports. Most slot-based processors come with either an active or a passive heatsink already installed. Start by positioning the two universal retention mechanism brackets on either side of the processor slot so that the holes in the brackets line up with the holes in the motherboard (see Figure 22.5). Push the included fasteners through the mounting holes in the retention bracket and the motherboard until you feel them snap into place. Insert the fastener retainer pins through the holes in the fastener to lock them into place. Then, slide the processor/heatsink down between the brackets until it is firmly seated in the slot. The latches on the top sides of the processor lock into place when the processor is fully seated. Install the heatsink supports into the holes provided in the motherboard and processor.

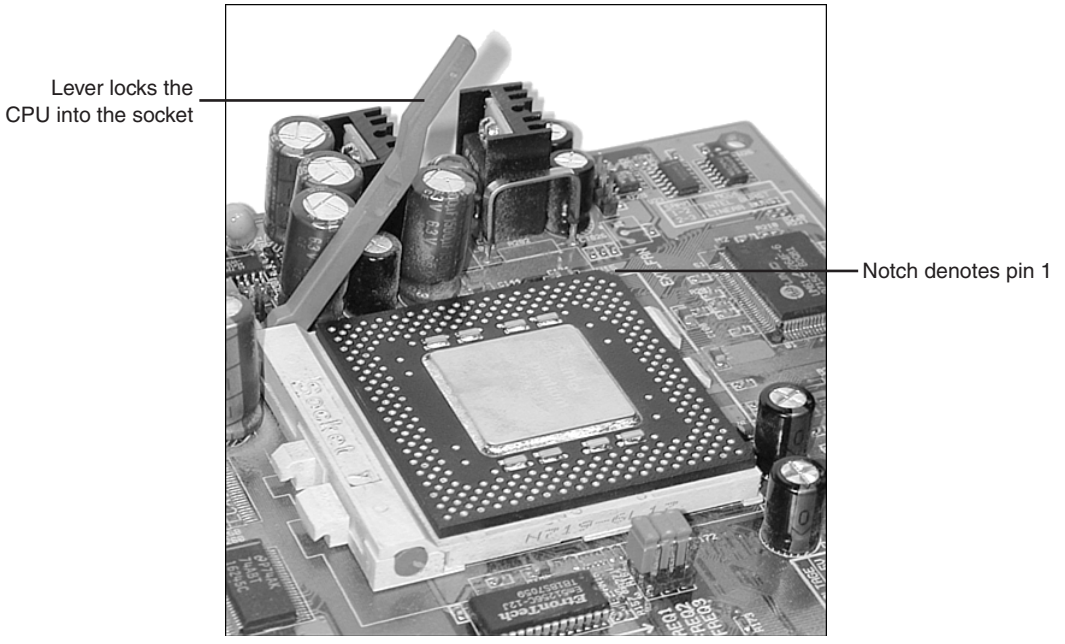

Figure 22.4 The lever on a ZIF socket locks the processor into the socket when lowered. Note the notch on the corner of the processor, denoting pin 1.

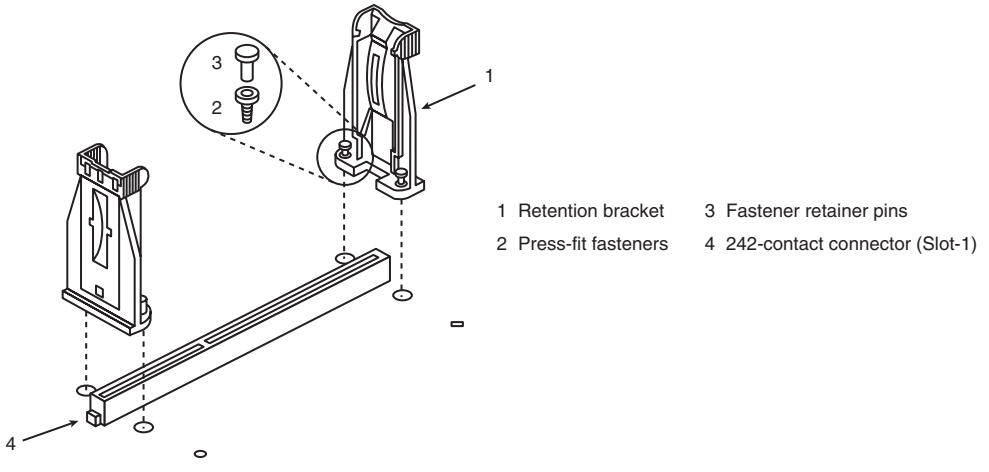

Figure 22.5 Universal retention mechanism for slot-based processors. *Illustration used by permission of Intel Corporation.*

If the CPU does not already have a heatsink attached to it, attach it now. Most heatsinks clip either to the CPU or to the socket with one or more retainer clips (see Figure 22.6). Be careful

when attaching the clip to the socket; you don't want it to scrape against the motherboard, which can damage circuit traces or components. In most cases, you should put a dab of heatsink thermal transfer compound (normally a white-colored grease) on the CPU before installing the heatsink. This prevents any air gaps and enables the heatsink to work more efficiently. If the CPU has an active heatsink (with a fan), plug the fan power connector into one of the fan connectors supplied on the motherboard (see Figure 22.7). Optionally, some heatsinks use a disk drive power connector for fan power.

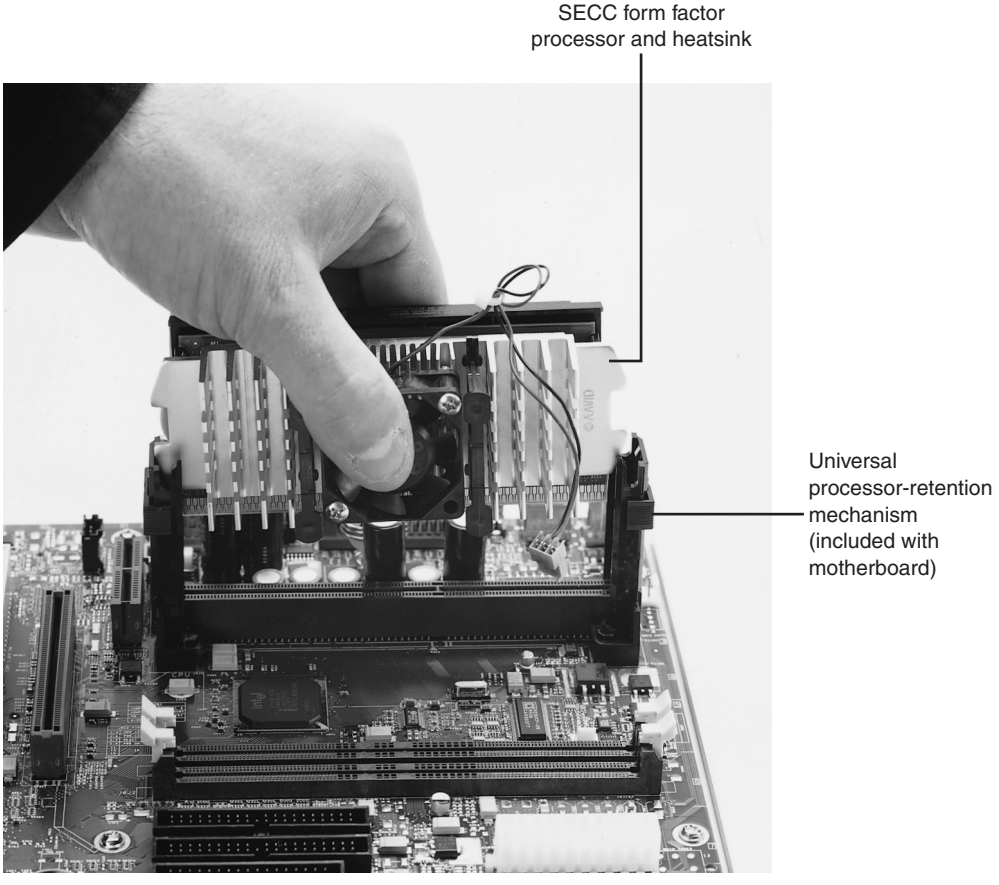

Figure 22.6 Installing a slot-based (single edge contact cartridge, or SECC) processor and attaching the heatsink fan power connector. *Motherboard and processor courtesy of Intel Corporation.*

3. Refer to the motherboard manufacturer's manual to set the jumpers, if any, to match the CPU you are going to install. Look for the diagram of the motherboard to find the jumper location, and look for the tables for the correct settings for your CPU. If the CPU was supplied already installed on the motherboard, the jumpers should already be correctly set for you, but it is still a good idea to check them.

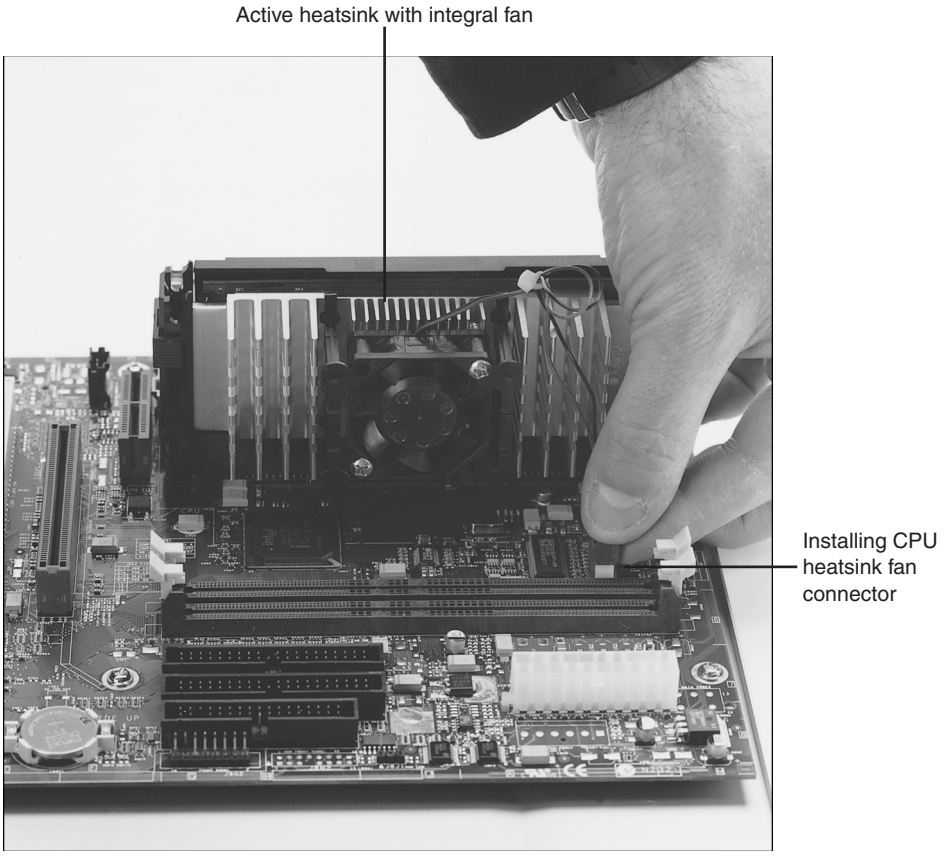

Figure 22.7 Attaching the heatsink fan power connector. *Motherboard and processor courtesy of Intel Corporation.*

Install Memory Modules

To function, the motherboard must have memory installed on it. Modern motherboards use either DIMMs or RIMMs. Depending on the module type, it will have a specific method of sliding into and clipping to the sockets. Usually, you install modules in the lowest-numbered sockets or banks first. Note that some boards require modules to be installed in pairs; this is most common with boards that use dual-channel RDRAM. Consult the motherboard documentation for more information on which sockets to use first and in what order and how to install the specific modules the board uses.

◀◀ See "Memory Basics," p. 416.

Memory modules frequently are keyed to the sockets by a notch on the side or bottom, so they can go in only one way. Figure 22.8 shows how to install a DIMM or RIMM; Figure 22.9 shows how to install a SIMM. More detailed instructions for installing DIMMs, RIMMs, and SIMMs can be found in Chapter 6.

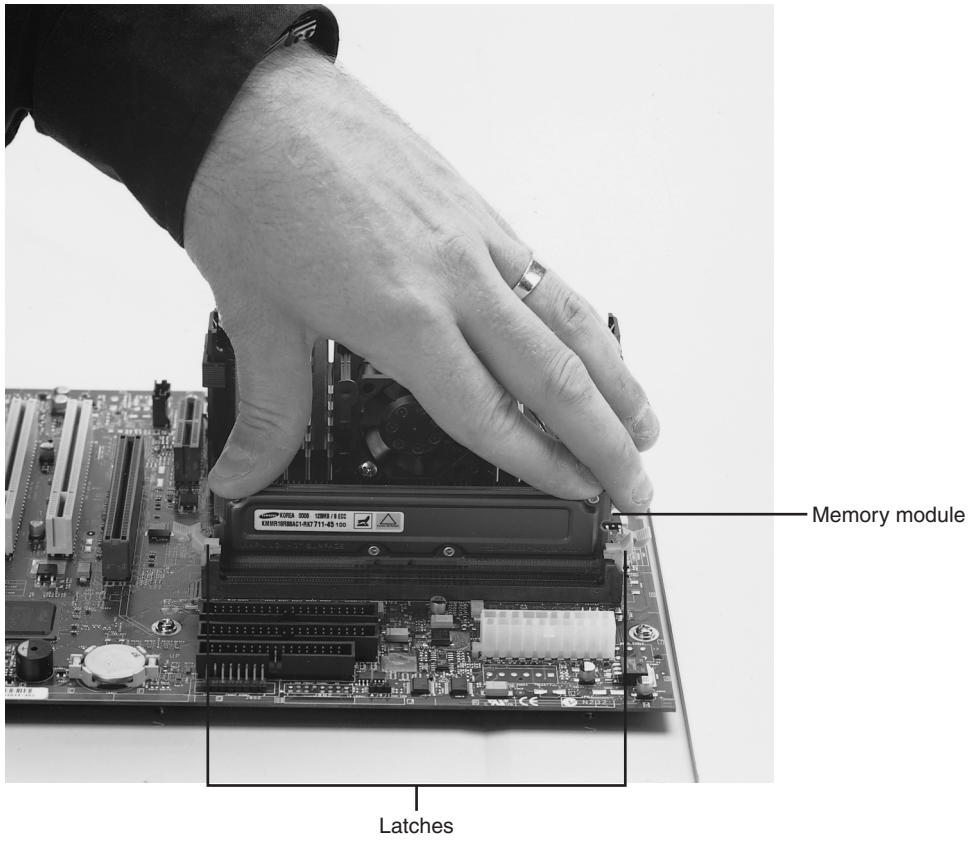

Figure 22.8 Installing the memory modules. *Motherboard courtesy of Intel Corporation.*

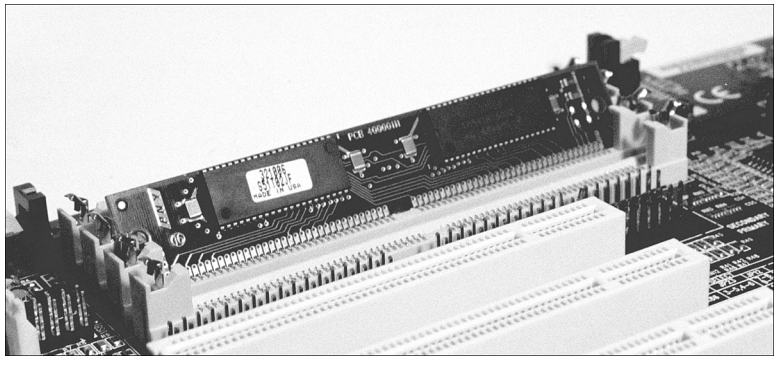

Figure 22.9 Insert SIMMs into the socket at an angle; then press forward to engage the retaining clips.

Caution

Be careful not to damage the connector. If you damage the motherboard memory connector, you could be facing an expensive repair. Never force the module; it should come out easily. If it doesn't, you are doing something wrong.

Mount the New Motherboard in the Case

The motherboard attaches to the case with one or more screws and often several plastic standoffs. If you are using a new case, you might have to attach one or more metal spacers or plastic standoffs in the proper holes before you can install the motherboard. Use the following procedure to install the new motherboard in the case:

1. Find the holes in the new motherboard for the metal spacers and plastic standoffs. You should use metal spacers wherever there is a ring of solder around the hole. Use plastic standoffs where there is no ring of solder (see Figure 22.10). Screw any metal spacers into the new case in the proper positions to align with the screw holes in the motherboard.

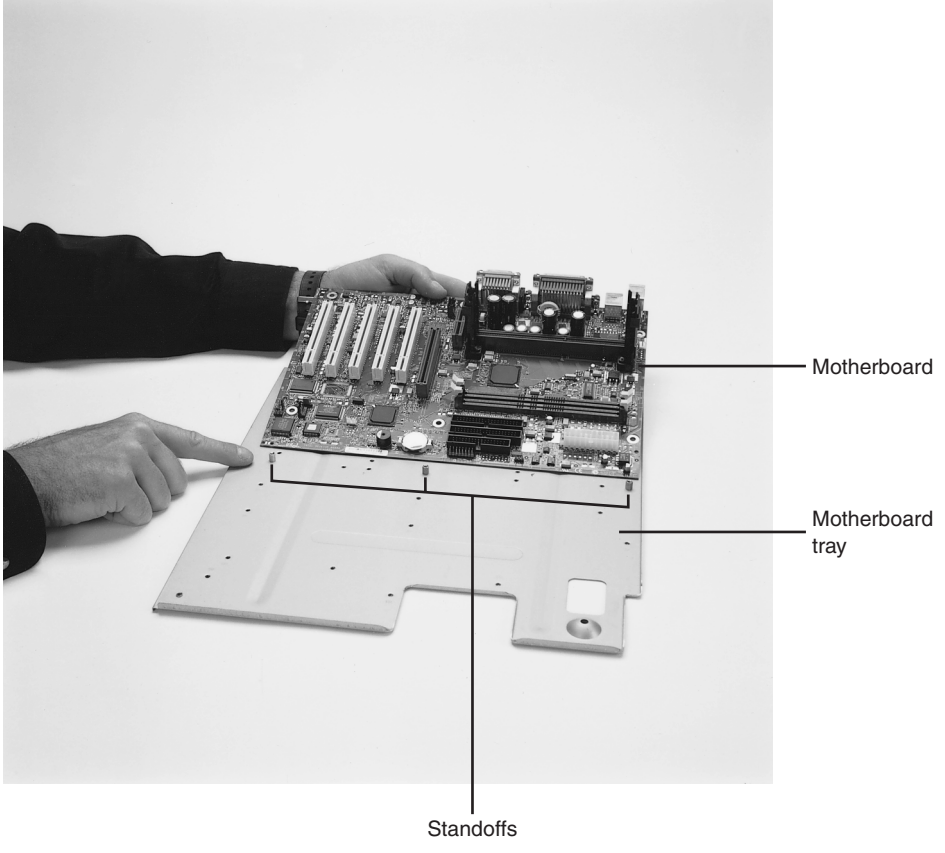

Figure 22.10 Make sure the standoffs align with the holes in the motherboard. *Motherboard courtesy of Intel Corporation.*

2. Most motherboards today attach directly to the chassis or to a removable motherboard tray with screws that thread into brass standoffs attached to the chassis or tray. Figure 22.11 shows three types of standoffs, including two brass types and one plastic. One screws directly to the chassis or tray, whereas the others attach to the motherboard and then slide into notches in the case or tray.

Figure 22.11 Various types of motherboard standoffs, used to support the board when installed in the chassis or motherboard tray.

   If the board uses the type of standoff that fits into slots in the chassis or tray, rather than screwing directly in, insert the standoffs directly into the new motherboard from underneath until they snap into place (see Figure 22.12). Or attach them to the board with a screw if necessary. Figure 22.13 shows a typical ATX-style motherboard with arrows indicating the typical location of the screw holes for mounting the motherboard to the case (see your motherboard manual for the exact location of these screw holes).

   After you have inserted the standoffs and lined them up with the screw holes on the motherboard, carefully attach the screws to secure the motherboard to the motherboard tray or case, depending on your chassis design (see Figure 22.14). Note the use of the thumb and forefinger to stabilize the screwdriver tip. This prevents accidental slippage of the screwdriver tip off of the screw, which is one of the biggest causes of new board failures.

3. Install the I/O shield (if used) into the chassis by snapping it into place (see Figure 22.15).

4. Install the new motherboard into the case or motherboard tray. Either screw it directly to the standoffs or slide the standoffs already attached to the board by sliding the entire board into position. Be sure you align the I/O shield with the case or the ports on the back of the board with the I/O shield already in the case. Often, you will have to set the board into the case and slide it sideways to engage the standoffs into the slots in the case. When the board is in the proper position, the screw holes in the board should be aligned with all the metal spacers or screw holes in the case. Figure 22.16 shows a motherboard attached to a motherboard tray being installed in the chassis.

   Some cases and boards, particularly ATX types, don't use any plastic spacers. Instead they use up to seven screws into metal standoffs that are installed in the case (refer to Figure 22.10). These are somewhat easier to install because the board drops into place and doesn't require that it be moved to the side to engage any standoffs.

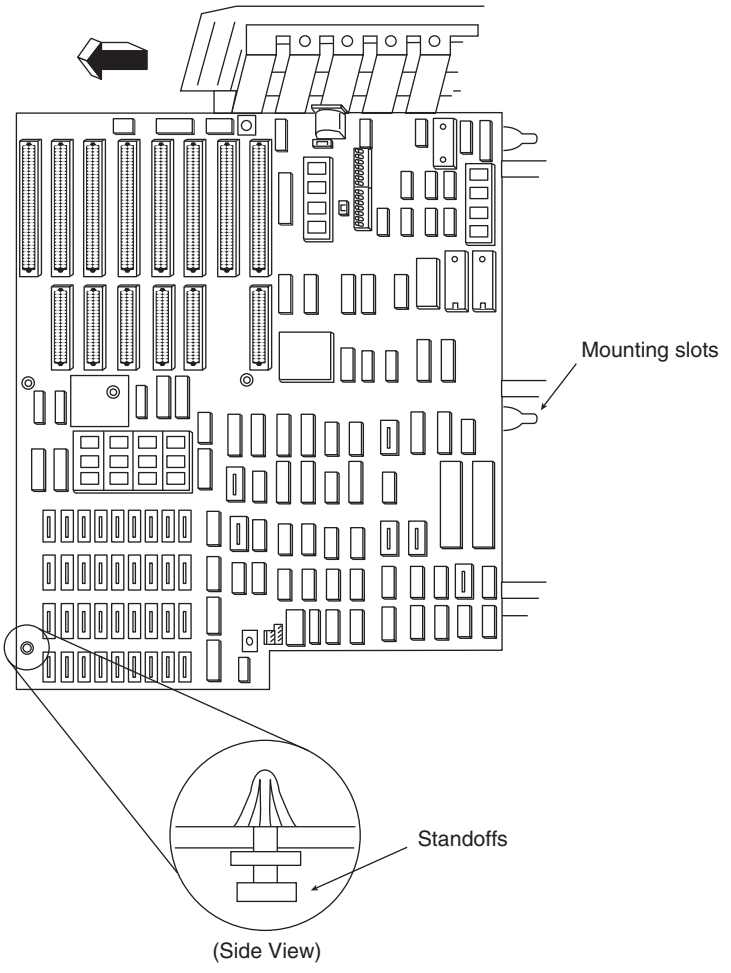

Figure 22.12 Insert standoffs into their mounting slots.

5. Take the screws and any plastic washers that were supplied with the new motherboard and screw the board into the case (see Figure 22.17).

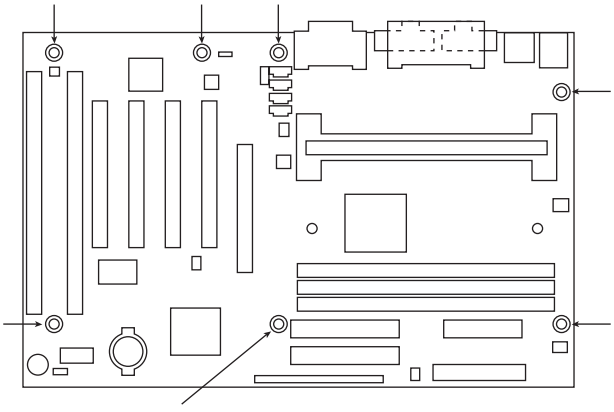

Figure 22.13 Mounting screw holes in a typical ATX motherboard. The arrows mark the screw holes for mounting the motherboard to the case.

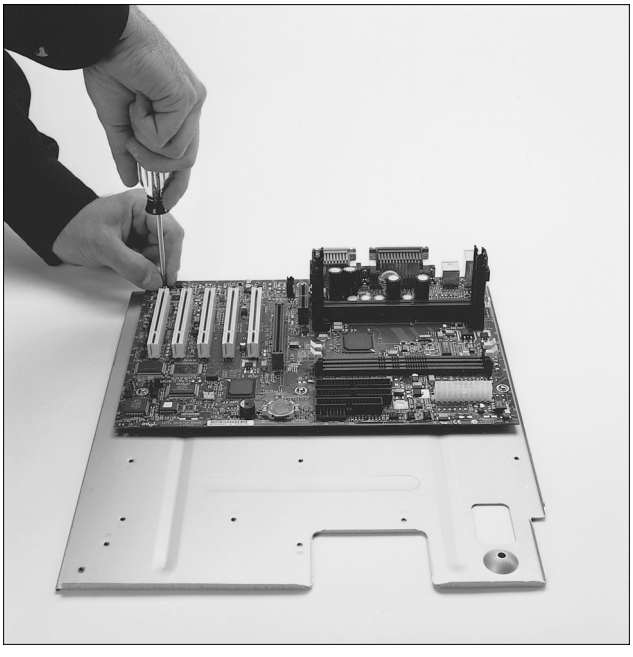

Figure 22.14 Attaching the motherboard to the motherboard tray. *Motherboard courtesy of Intel Corporation.*

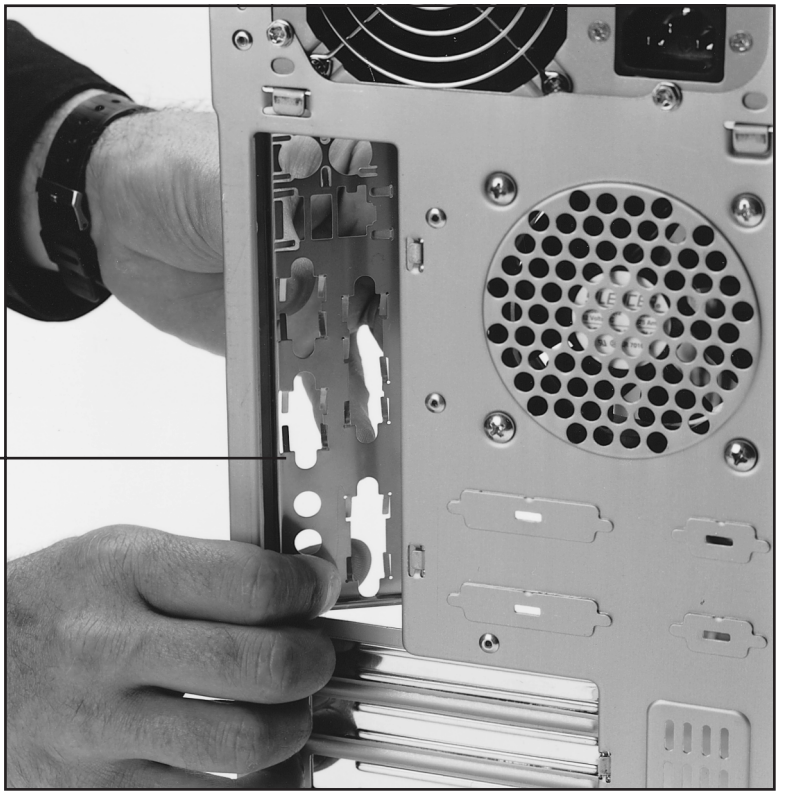

Figure 22.15 Snapping the I/O shield into place in the chassis. *Case courtesy of PC Power & Cooling, Inc.*

Figure 22.16 Installing the motherboard and tray into the chassis. *Case courtesy of PC Power & Cooling, Inc. Motherboard courtesy of Intel Corporation.*

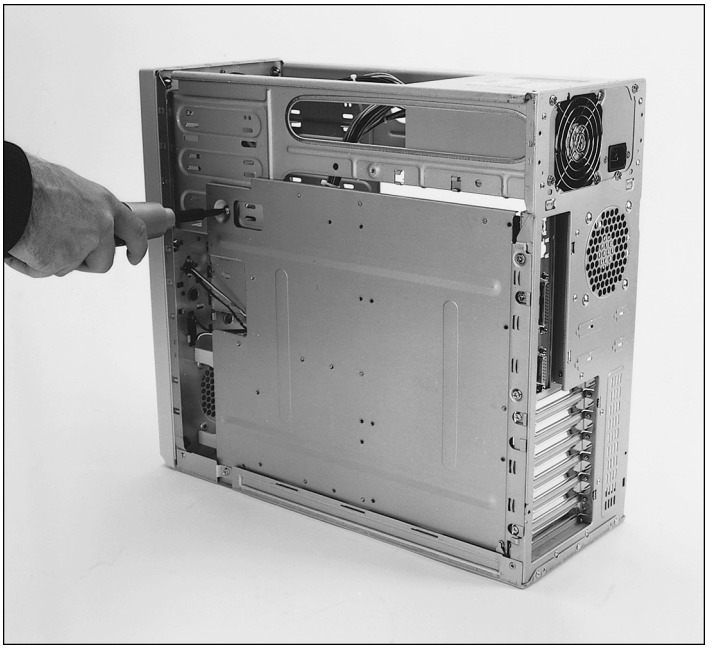

Figure 22.17 Installing the screws that hold the motherboard tray to the chassis. *Case courtesy of PC Power & Cooling, Inc.*

Connect the Power Supply

The power supply is very easy to install, and it usually attaches to the chassis with four screws. Figures 22.18 and 22.19 show installing the power supply into the chassis and tightening the screws.

ATX-style motherboards have a single power connector that can go on only one way and an optional secondary connector that is also keyed (see Figure 22.20). Baby-AT and other style board designs usually have two separate six-wire power connectors from the power supply to the board, which might not be keyed and therefore might be interchangeable. See Chapter 21 for important information on proper installation of Baby-AT power supplies. Even though you might be able to insert them several ways, only one way is correct! These power leads usually are labeled P8 and P9 in most systems. The order in which you connect them to the board is crucial; if you install them backward, you can damage the motherboard when you power it up. Many systems use a CPU cooling fan, which should also be connected. To attach the power connectors from the power supply to the motherboard, do the following:

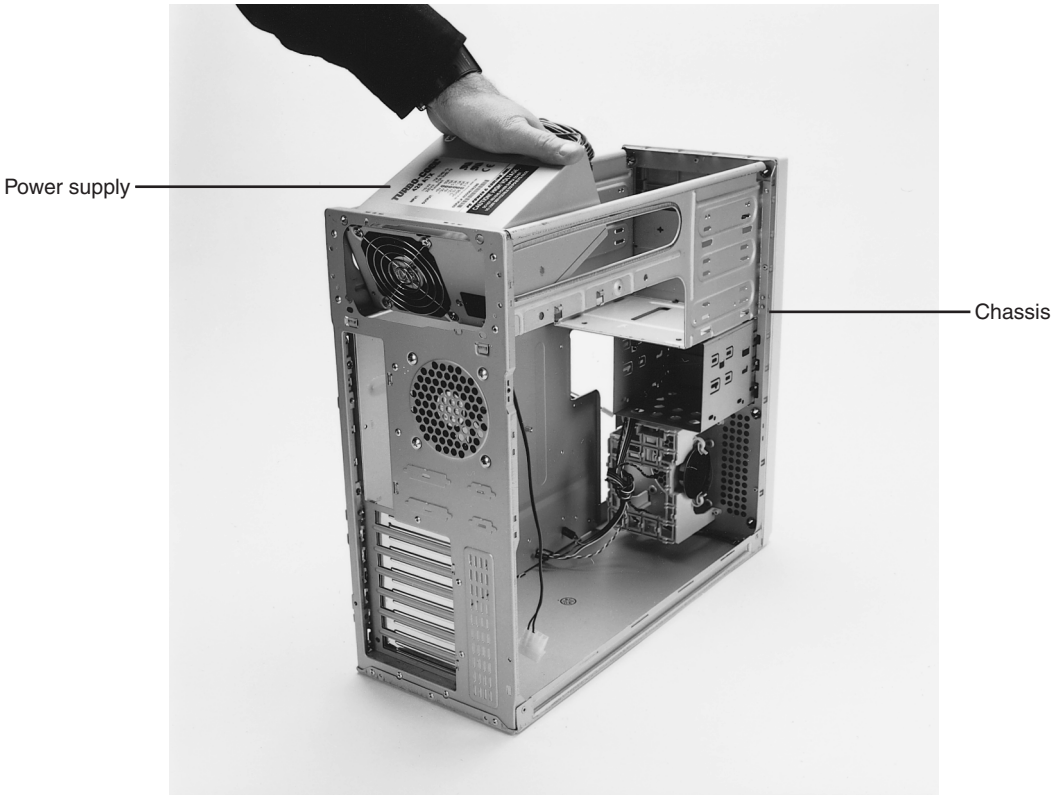

Figure 22.18 Installing the power supply into the chassis. *Case and power supply courtesy of PC Power & Cooling, Inc.*

1. If the system uses a single ATX-style power connector, plug it in; it can go on only one way. Some ATX systems also use a 6-pin auxiliary connector as well as a 4-pin ATX12V connector. These are also keyed and plug in only one way. If the system is not ATX and two separate six-wire connectors are used instead, the two black ground wires on the ends of the connectors must meet in the middle. Align the power connectors such that the black ground wires are adjacent to each other and plug in the connectors. Consult the documentation with your board to ensure that the power supply connection is correct. Incorrectly connecting the power connectors can destroy the motherboard.

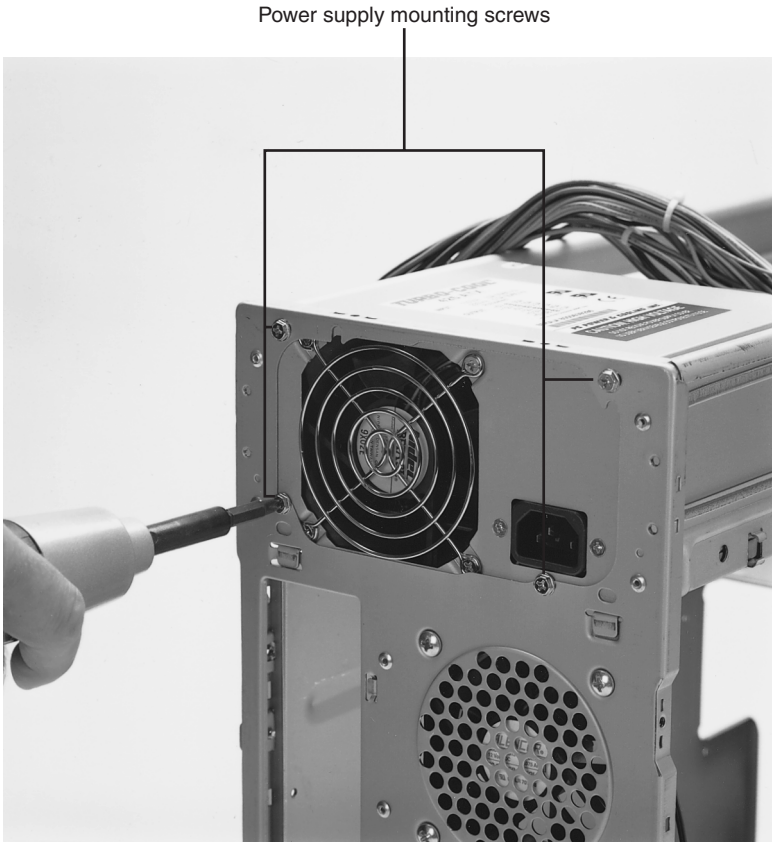

Figure 22.19 Installing the screws to retain the power supply. *Case and power supply courtesy of PC Power & Cooling, Inc.*

2. Plug in the power lead for the CPU fan if one is used. The fan will either connect to the power supply via a disk drive power connector or connect directly to a fan power connector on the motherboard.

◀◀ See "AT Power Supply Connectors," p. 1169.

Note

See Chapter 21 of this book for detailed coverage of the various types of power supply connectors, including new connectors used with the Intel Pentium 4.

Connect I/O and Other Cables to the Motherboard

Several connections must be made between a motherboard and the case. These include LEDs for the hard disk and power, an internal speaker connection, a reset button, and a power button. Most modern motherboards also have several built-in I/O ports that have to be connected. This includes dual IDE host adapters, a floppy controller, dual serial ports, and a parallel port. Some boards also include additional items such as built-in video, sound, or SCSI adapters.

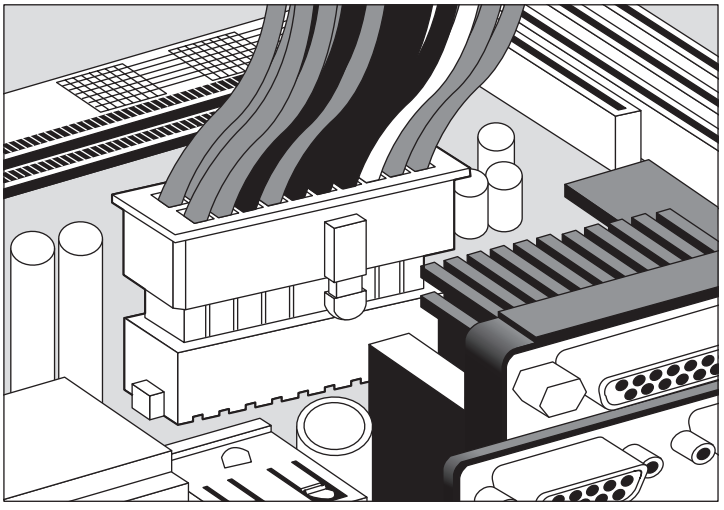

Figure 22.20 Attaching an ATX motherboard power connector.

If the board is an ATX type, the connectors for all the external I/O ports are already built into the rear of the board. If you are using a legacy Baby-AT-type board, you might have to install cables and brackets to run the serial, parallel, and other external I/O ports to the rear of the case (see Figures 22.21 and 22.22).

If your motherboard has onboard I/O (nearly all PCs today use onboard I/O), use the following procedure to connect the cables:

1. Connect the floppy cable between the floppy drives and the 34-pin floppy controller connector on the motherboard.
2. Connect the IDE cables between the hard disk, IDE CD-ROM, and 40-pin primary and secondary IDE connectors on the motherboard (see Figure 22.23). Typically, you will use the primary IDE channel connector for hard disks only and the secondary IDE channel connector to attach an IDE CD-ROM or other device, such as a tape drive.

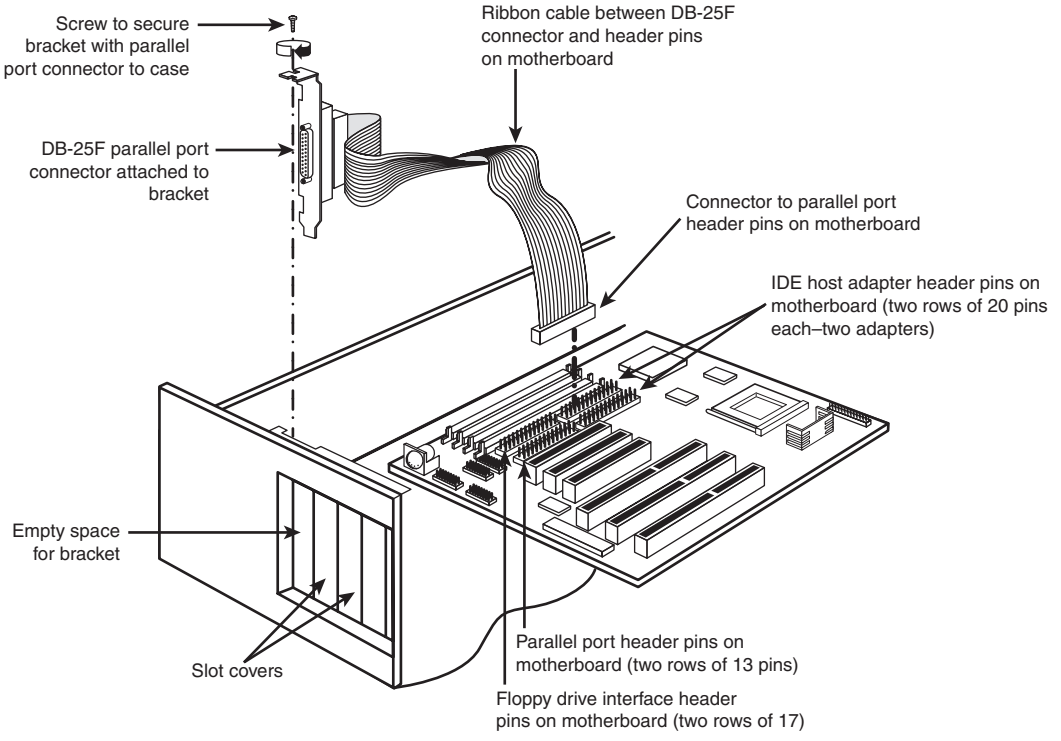

Figure 22.21 This parallel port header cable provides an external DB-25F parallel port connector for a typical Baby-AT motherboard.

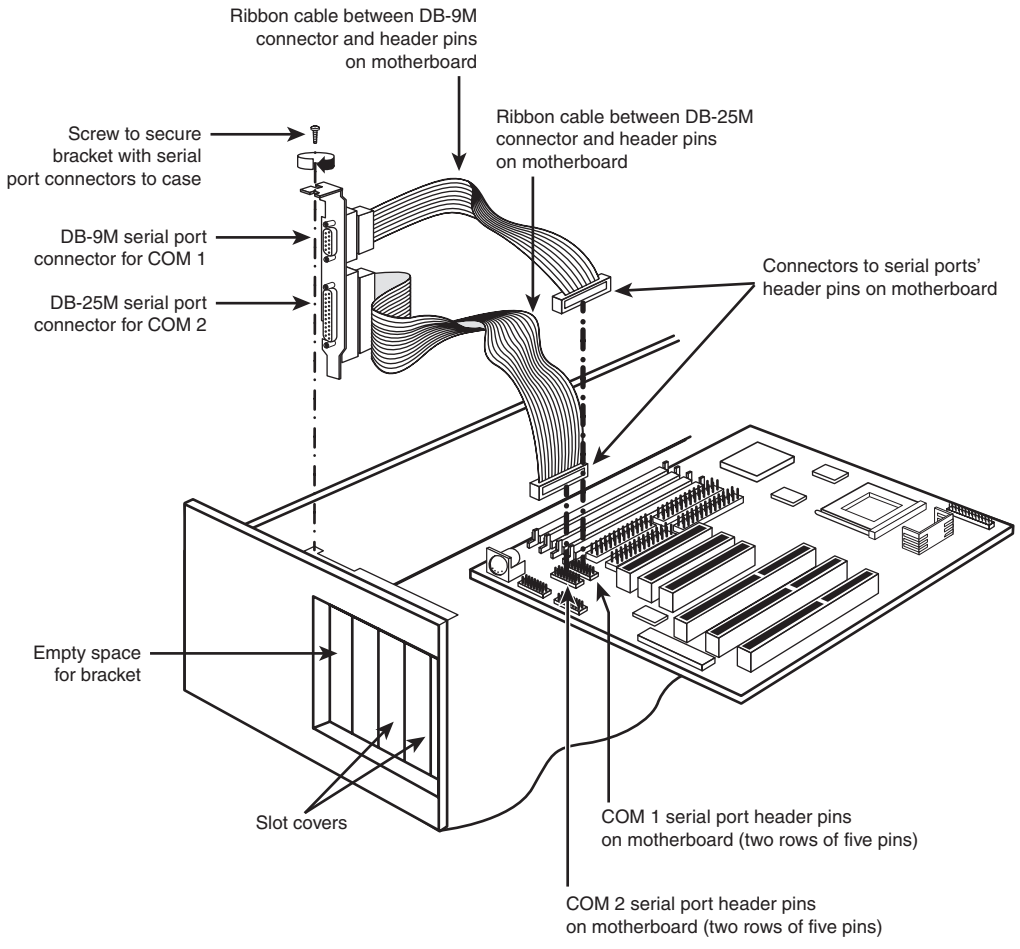

Figure 22.22 This serial port header cable provides two external serial port connections (a DB-9M and a DB-25M) for a typical Baby-AT motherboard.

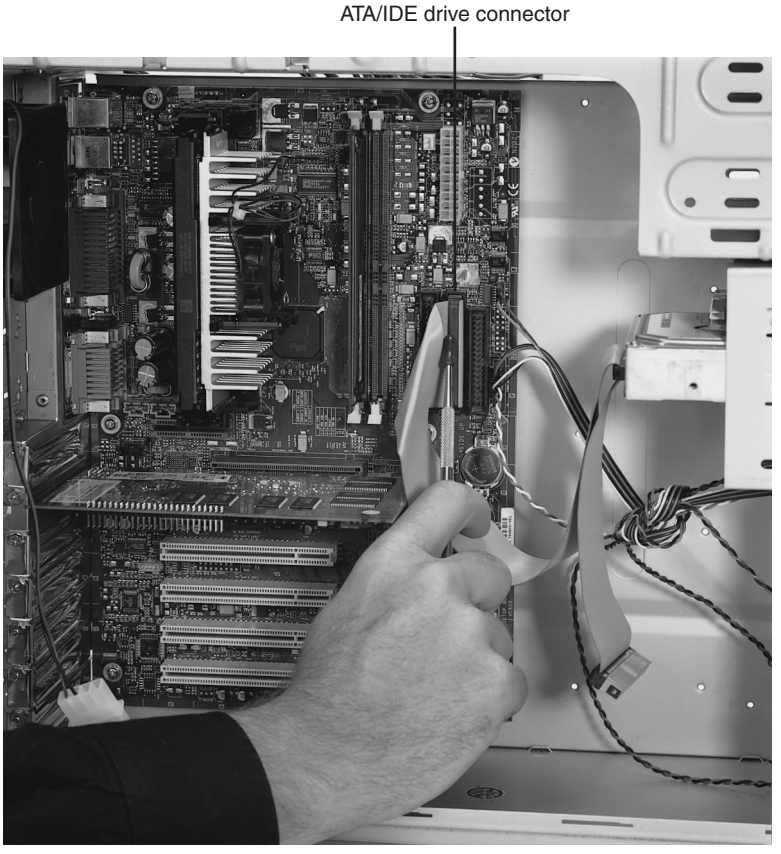

Figure 22.23 ATA drive connectors. *Motherboard courtesy of Intel Corporation.*

3. On non-ATX boards, a 25-pin female cable port bracket is used for the parallel port. Usually two serial ports exist: a 9-pin and either another 9-pin or a 25-pin male connector port. Align pin 1 on the serial and parallel port cables with pin 1 on the motherboard connector, and then plug them in.
4. If the ports don't have card slot-type brackets or if you need all your expansion slots, the back of the case might have port knockouts you can use instead. Find ones that fit the ports, and push them out, removing the metal piece covering the hole. Unscrew the hex nuts on each side of the port connector, and position the connector in the hole. Install the hex nuts back in through the case to hold the port connector in place.
5. Most newer motherboards also include a built-in mouse port. If the connector for this port is not built into the back of the motherboard (typically next to the keyboard connector), you probably have a card bracket-type connector to install. In that case, plug the cable into the motherboard mouse connector and then attach the external mouse connector bracket to the case.

6. Attach the front-panel switch, LED, and internal speaker wires from the case front panel to the motherboard. If they are not marked on the board, check where each one is on the diagram in the motherboard manual. Figure 22.24 shows the front-panel connectors.

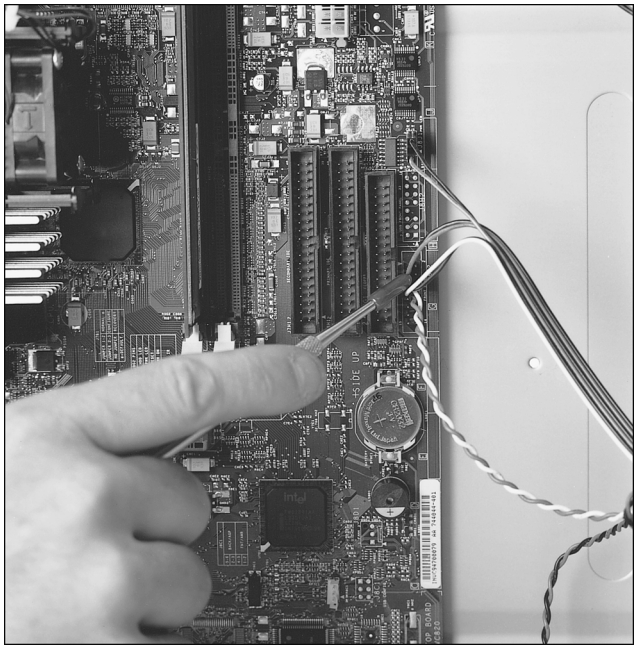

Figure 22.24 Motherboard front-panel connectors (speaker, power switch, LEDs, and so on). *Motherboard courtesy of Intel Corporation.*

Install the Drives

At this point you should install your hard drive, floppy drive, CD-ROM or DVD drive, and optionally your CD-RW drive. This is covered in detail in Chapter 14, "Physical Drive Installation and Configuration."

The basic process for mounting CD, hard drives, and floppy drives is as follows:

1. Remove the drive bay plates (if needed). Simply bend or knock the plate out of the way.
2. To install a CD drive, simply slide the drive into the chassis. Note that it is easier to connect the IDE cable to the rear of the drive and make jumper selections before mounting the drive. See Chapters 7 and 14 for more about IDE jumpers and drive installation. Note that some cases come with rails that must be added to 5 1/4" wide drives, such as the CD. In such cases, use the screws from step 3 for the drive rails.
3. After the drive is in the bay, line up the drive mounting screw holes on the drive with the holes in the case chassis. Secure the drive with four screws, using the ones that came with your case or the drive you are installing (see Figure 22.25). If the drive uses rails, the rails hold the drive in place.

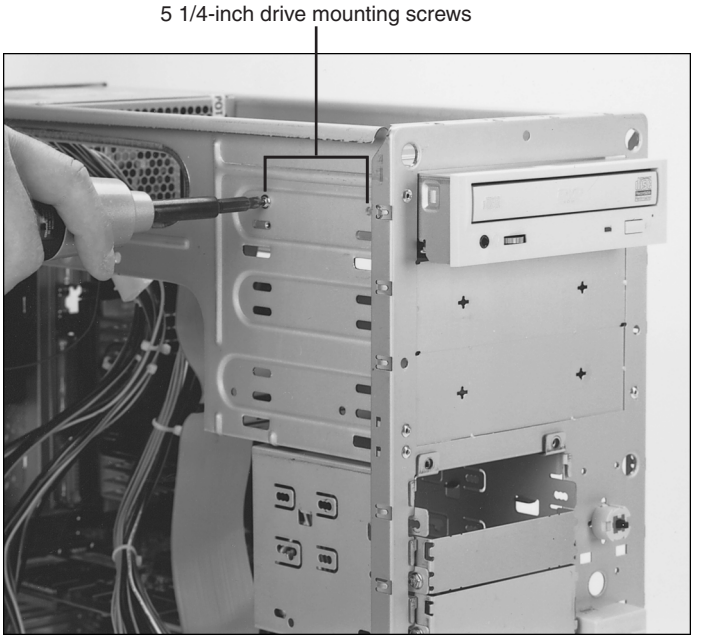

Figure 22.25 Secure the drive to the chassis using four screws. *Chassis courtesy of PC Power & Cooling, Inc. CD drive supplied by Micro X-Press.*

4. Connect the other end of the IDE cable to your motherboard's IDE connector or to the back of another IDE device if you are chaining drives.
5. To install floppy and hard drives, remove the drive cage (if your case has a removable drive cage). Slide your drives into the drive cage and secure them with the screws that came with your case or with the drive you are installing (see Figure 22.26). As with the CD drive, it's easier to connect the floppy and IDE cables to the rear of the drives and make any jumper selections prior to placing the drives or the drive cage into the chassis.

Note

If your chassis does not include a removable drive cage, you'll simply have to mount the drives in the chassis. This is a little more difficult because there's not much working room inside a PC.

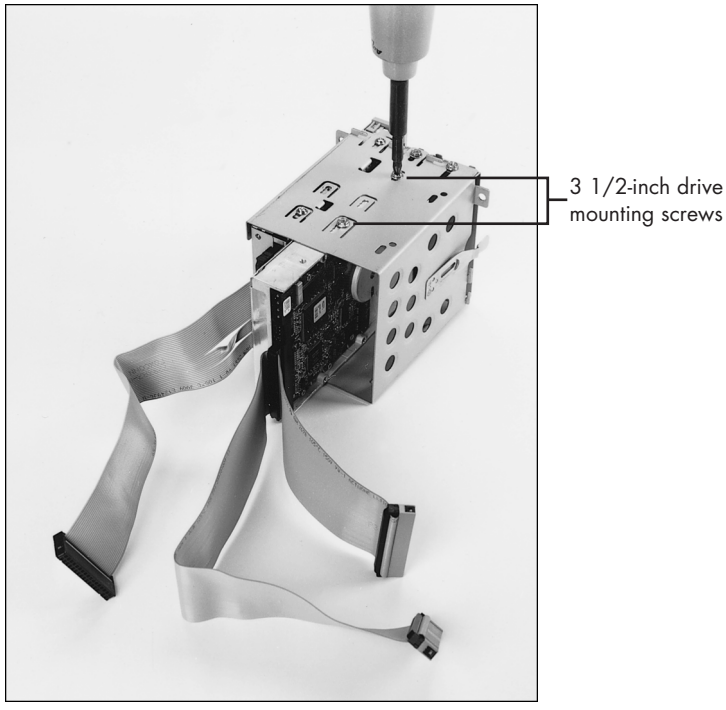

Figure 22.26 Use four screws to secure each drive to the drive cage. *Chassis courtesy of PC Power & Cooling, Inc. Hard drive supplied by Micro X-Press.*

6. Slide the drive cage back into the PC and secure it to the chassis using the screws provided with your case (see Figure 22.27).
7. Connect the drive cables to the appropriate locations on your motherboard. See Chapters 7 and 14 for more about jumper setting and cable connections for hard drives and floppy drives.

Remove the Existing Video Card (If Present)

If you are replacing an existing video card (or switching from onboard video to an add-in video card), you should remove the existing installed video driver before powering down to install the new card. This helps prevent the system from improperly identifying the new video card and makes for a smoother upgrade. To do this, open the Device Manager, select the existing Display Adapter, and select Remove or Uninstall. Do not reboot the system if asked; instead you can power down and remove the existing video card.

To physically remove the card, use the following procedure:

1. Shut down and unplug both the system and monitor.
2. Disconnect the video cable running from the monitor to the card.

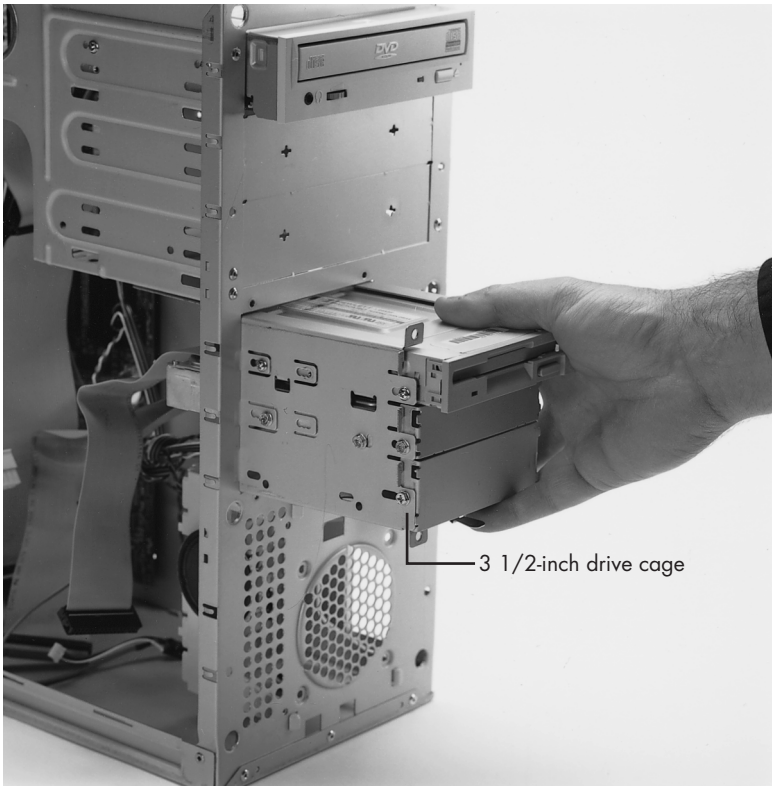

Figure 22.27 The drive cage inserts into the chassis and is usually held in place by two or four screws. *Chassis courtesy of PC Power & Cooling, Inc. Hard drive supplied by Micro X-Press.*

3. Open the system.
4. If you are not using an ESD ground wire, touch the side of the power supply to avoid ESD damage to your hardware.

◀◀ To learn how to avoid ESD, see "ESD Protection," p. 1236.

5. Remove the screw holding the video card in place.
6. If there are any cables running from your video card to other devices (such as a sound card or DVD decoding board), note their locations and then remove them.
7. Remove the video card from the slot.

In the case of systems that have video card functions built into the motherboard or chipset, usually just installing a new card into an open AGP/PCI slot automatically disables the existing video. In some cases you might have to set a specific jumper on your motherboard to disable any built-in video (refer to your motherboard's documentation). Now you are ready to install a new video card.

Installing the New Video Card and Driver Software

Follow these steps to install a new video card into a system:

1. If necessary, remove the screw and slot cover behind the expansion slot you want to use for the new video card.
2. Slide the video card straight down into the slot where it will be installed.
3. Push the card down into the slot, using a front to back rocking motion if necessary to get the edge connector to slide into the slot.
4. Use either the screw you removed during removal of the old card or the screw used in step 1 to fasten the card into place.
5. Attach the video cable from the monitor to the proper connector at the rear of the monitor. If the new card uses a DVI-I connector and the monitor uses the standard 15-pin VGA connector, use a DVI-to-VGA adapter (usually provided with the video card or available separately from stores that stock computer parts).

After the entire system is assembled, when the system boots up, Windows should detect the new video card and automatically begin the driver installation process. At that point, follow the manufacturer's instructions for installing the latest video drivers for the new video card. After the video card drivers are installed, you can use the Windows Display properties to fine-tune its settings for resolution, color depth, or refresh rate if desired.

Note

If you have installed a video card with multiple-monitor support and your existing display still works, you might want to attach it to the secondary display port on your new display card and use it as a second monitor. Dual-display-capable cards are now widely available, using ATI, NVIDIA, and Matrox chipsets. For details, see the section "Multiple Monitors" in Chapter 15.

Install Additional Expansion Cards

Many systems use additional expansion cards for network interface, Internet connection (modem), sound, and SCSI adapters. These cards are plugged into the bus slots present on the motherboard. To install these cards, follow these steps:

1. Insert each card by holding it carefully by the edges, being sure not to touch the chips and circuitry. Put the bottom-edge finger connector into a slot that fits. Firmly press down on the top of the card, exerting even pressure, until it snaps into place (see Figure 22.28).
2. Secure each card bracket with a screw (see Figure 22.29).
3. Attach any internal cables you might have removed earlier from the cards.

Replace the Cover and Connect External Cables

Now the system should be nearly assembled. All that remains is installing the cover assembly and connecting any external devices that are cabled to the system. I usually don't like to install the case cover screws until I have tested the system and am sure everything is working properly. Often, I find that a cable has been connected improperly or some jumper setting is not correct, requiring that I remove the cover to repair the problem. Use the following procedure to complete the assembly:

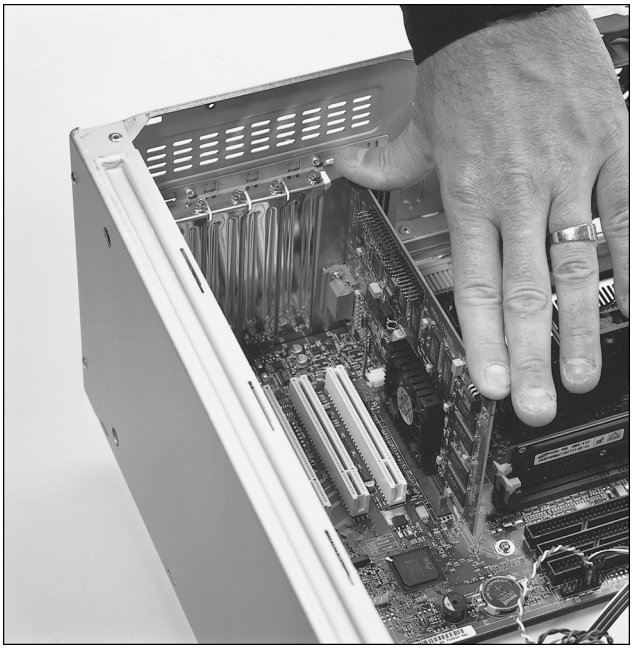

Figure 22.28 This photo shows a video adapter being inserted into the slot. *Motherboard courtesy of Intel Corporation.*

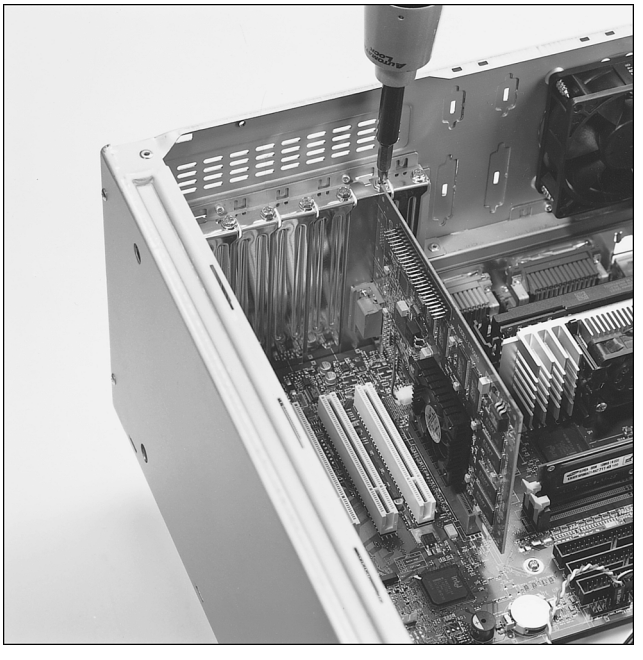

Figure 22.29 Installing the screw to retain the card. *Motherboard courtesy of Intel Corporation.*

1. Slide the cover onto the case.
2. Before powering up the system, connect any external cables. Most of the connectors are D-shaped and go in only one way.
3. Plug the 15-pin monitor cable into the video card female connector.
4. Attach the phone cord to the modem, if any.
5. Plug the round keyboard cable into the keyboard connector, and plug the mouse into the mouse port or serial port (if you are using a serial mouse).
6. If you have any other external cabling, such as joystick or audio jacks to a sound card, attach them now.

Run the Motherboard BIOS Setup Program (CMOS Setup)

Now that everything is connected, you can power up the system and run the BIOS Setup program. This enables you to configure the motherboard to access the installed devices and set the system date and time. The system also tests itself to determine whether any problems exists. Do the following:

1. Power on the monitor first and then the system unit. Observe the operation via the screen and listen for any beeps from the system speaker.
2. The system should automatically go through a power on self test (POST) consisting of video BIOS checking, a RAM test, and usually an installed component report. If a fatal error occurs during the POST, you might not see anything onscreen and the system might beep several times, indicating a specific problem. Check the motherboard or BIOS documentation to determine what the beep codes mean.
3. If there are no fatal errors, you should see the POST display onscreen. Depending on the type of motherboard BIOS, such as Phoenix, AMI, Award, or others, you have to press a key or series of keys to interrupt the normal boot sequence and get to the Setup program screens that enable you to enter important system information. Normally, the system indicates via the onscreen display which key to press to activate the BIOS Setup program during the POST, but if not, check the motherboard manual for the key(s) to press to enter the BIOS Setup. Common keys used to enter BIOS Setup are F1, F2, F10, Esc, Ins, and Del.
4. After the Setup program is running, use the Setup program menus to enter the current date and time, your hard drive settings, floppy drive types, video cards, keyboard settings, and so on. Most newer motherboard BIOSes can autodetect the hard drive, so you should not have to manually enter any parameters for it.
5. Entering the hard drive information is most critical when building a new system. Most modern BIOSes feature an autodetect or auto-type setting for the drive; I recommend you choose that if it is available. This causes the BIOS to read the parameters directly from the drive, which eliminates a chance for errors—especially if the builder is less experienced. These parameters include CHS (cylinder head sector) specifications and transfer speed and translation settings. Most systems also let you set a *user-definable type*, which means that the cylinder, head, and sector counts for this type were entered manually and are not constant. If you set a user-definable type (not normally recommended unless you don't have "auto" as a choice), it is especially important to write down the exact settings you use because this information might be very difficult to figure out if it is ever lost.

   Modern ATA drives also have additional configuration items you should record. These include the translation mode and transfer speed setting. With drives larger than 528MB, you should record the translation mode, which is expressed differently in different BIOS versions. Look for settings such as CHS, ECHS (Extended CHS), Large (which equals ECHS), or LBA (logical block

addressing). Typically, you set LBA or Large for any drive over 528MB. Whatever you set, it should be recorded because changing this setting after the drive has been formatted can cause problems.

6. After you have checked all the settings in the BIOS Setup, follow the instructions onscreen or in the motherboard manual to save the settings and exit the Setup menu.

◀◀ See "Running or Accessing the CMOS Setup Program," p. 384.

Troubleshooting New Installations

At this point, the system should reset and attempt to boot normally from either a floppy disk or hard disk. With the operating system startup disk in drive A:, the system should boot and either reach an installation menu or an A: prompt. If any problems exist, here are some basic items to check:

- *If the system won't power up at all, check the power cord.* If the cord is plugged into a power strip, make sure the strip is switched on. Usually, a power switch can be found on the front of the case, but some power supplies have a switch on the back as well.
- *Check to see whether the power switch is connected properly inside the case.* There is a connection from the switch to the motherboard; check both ends to ensure that they are connected properly.
- *Check the main power connector from the supply to the board.* Make sure the connectors are seated fully, and if the board is a Baby-AT type, ensure that they are plugged in with the correct orientation and sequence.
- *If the system appears to be running but you don't see anything on the display, check the monitor to ensure that it is plugged in, turned on, and properly and securely connected to the video card.*
- *Check the video card to ensure it is fully seated in the motherboard slot.* Remove and reseat the video card, and possibly try a different slot if it is a PCI card.
- *If the system beeps more than once, the BIOS is reporting a fatal error of some type.* See the BIOS Error code listings in Chapter 5 and on the DVD accompanying this book for more information on what these codes mean because they depend on the type and version of BIOS you have. Also, consult your motherboard documentation—look in the BIOS section for a table of beep codes.
- *If the LED on your floppy drive, hard drive, or CD/DVD-ROM drive stays on continuously, the data cable is probably installed backward or is off by some pins.* Check that the stripe on the cable is properly oriented toward pin 1 on both the drive and board connector ends. Also, check the drive jumpers for proper master/slave relationships.

When you are sure the system is up and running successfully, power it off and screw the chassis cover securely to the case. Now your new system should be ready for the operating system installation.

Installing the Operating System

If you are starting with a new drive, you must install the operating system. If you are using a non-Windows operating system, follow the documentation for the installation procedures.

On a newer system in which you are installing an OEM version of Windows 98 or later (which comes on a bootable CD), there isn't really anything you need to do, other than simply booting from the CD (you might have to enable the CD-ROM as a boot device in your BIOS Setup) and following the prompts to install the OS. Windows 98 or later versions automatically recognize that the drive needs to be partitioned and the partitions formatted before the installation can proceed. Additionally,

Windows 98 or later versions execute these functions for you, with prompts guiding you along the way. This is the method I recommend for most people because it is relatively simple and straightforward.

If you want to do the partitioning and formatting manually (prior to installing the OS), follow the guidelines in the next few sections.

Partitioning the Drive

From the `A:>` prompt, with the startup disk inserted in the floppy drive, type the following command:

```
FDISK
```

This command is used to partition your drive. Follow the menus to create either a single partition for the entire drive or multiple partitions. Usually, the first partition must also be made active, which means it will be bootable. I recommend you answer Yes to the prompt `Do you wish to enable large disk support (Y/N)?` This enables the partition to be created using the FAT32 or NTFS file system. Then, you can continue accepting default entries for all the prompts to partition the drive as a single bootable partition that covers the entire drive.

Next, exit FDISK; this causes the system to restart.

Note

Using FDISK is covered extensively in Chapter 14.

Formatting the Drive

Afterto restart. rebooting on the startup floppy, you need to format each partition you've created. The first partition is formatted using the `FORMAT` command as follows:

```
FORMAT C:
```

All other partitions are formatted in the same manner: Merely run the command, changing the drive letter for each partition that needs to be formatted.

After the `FORMAT` command completes on all the drives, you should reboot again from the startup floppy. Now you are ready to install Windows.

Note

Drive formatting is covered extensively in Chapter 10, "Hard Disk Storage." See Chapter 14 for more details on installing and setting up a hard drive.

Loading the CD-ROM Driver

If your system supports booting from the CD and you are installing an OEM version of Windows 98 or later (which comes on a bootable CD), you can disregard this section because the CD-ROM drivers automatically are loaded as you boot from the CD. You can then either proceed with the installation from the CD or copy the OS files from the CD to the hard drive and install from the hard drive instead.

If you must first boot from a floppy (because your system can't boot from a CD or your version of Windows isn't bootable), you must make sure your startup floppy disk is properly configured to support the CD/DVD drive in your system. This requires that real-mode (DOS-based) drivers be installed on the disk that is compatible with your drive. The easiest solution is to use a Windows 98 or later

startup floppy disk because it is already prepared with the proper drivers for 99% of all systems on the market. Even if you are installing Windows 95, you can still use the Windows 98 or later startup disk to start the process.

If you are using a Windows 95 startup disk and you don't have the CD-ROM drivers on it, you should look for a CD-ROM driver disk that usually comes with your drive. It should have a driver installation batch file on it which, if run, will copy the drivers to your startup disk and create the appropriate `CONFIG.SYS` and `AUTOEXEC.BAT` files to enable CD-ROM support. If the driver is called `CDROM.SYS`, that file—along with the following line (or something similar)—should be added to the `CONFIG.SYS` file on your Windows 95 startup disk:

```
device=CDROM.SYS /D:oemcd001
```

This causes the `CDROM.SYS` driver to be loaded and assigns it an in-memory driver designation of `oemcd001`. Any designation can be used here, but it should be eight characters or fewer and must match a similar designation in the next step.

Next, you must load the Microsoft CD-ROM extensions driver in your `AUTOEXEC.BAT` file. This driver is called `MSCDEX.EXE` and is already included on the Windows 95 startup disk. If you used the designation I listed in the previous step, add the following line to the `AUTOEXEC.BAT` file on the Windows 95 startup disk:

```
LH MSCDEX.EXE /D:oemcd001
```

This loads the `MSCDEX.EXE` driver (in upper memory via the `LH` or `LoadHigh` command if possible) and looks to attach to the CD-ROM driver loaded earlier via the driver designation `oemcd001` in this case.

After these statements are added to the `CONFIG.SYS` and `AUTOEXEC.BAT` files, you should reboot on the startup floppy. Now you also should be able to access your CD-ROM drive. It will appear one drive letter after your last drive partition. If your hard disk partitions are C: and D:, the CD-ROM drive will be E:.

Note that these procedures require that you find your CD-ROM driver and copy it onto the startup disk. If you can't find the driver or have a SCSI hard disk (which uses different types of drivers), I recommend you borrow a copy of a Windows 98 or later version startup disk. These startup disks already include a series of drivers that work with virtually any CD-ROM drive on the market, even SCSI versions.

After you have successfully created a startup disk with the CD-ROM drivers (or have the Win98 startup disk), insert the Windows CD-ROM in your CD/DVD drive. After booting from the startup floppy, change to the CD/DVD drive letter. Then at that prompt, run the `SETUP` command. This starts the Windows installation program. From here, you can follow the prompts to install Windows as you see fit. This procedure can be somewhat lengthy, so be prepared to spend some time. You will be installing not only Windows, but also the drivers for any hardware detected during the installation process.

Whether you are booting from floppy or CD, I recommend copying the Windows files to your hard disk and actually running the installation from the hard disk and not the CD. This is helpful in the future should you want to reinstall or install any additional parts of Windows because it will then work directly from the hard disk and you won't be asked to insert the CD.

To do this, first check the CD for the directory containing the *.CAB files and copy them to the hard disk. For example, using Windows 98 it would go something like this:

```
copy E:\WIN98\*.* C:\WIN98 /S
```

This copies all the files from the WIN98 directory on the CD-ROM (E: drive in this example) to the hard disk and places them in a directory called WIN98. Then, you can remove the CD (it is no longer needed) and run the installation directly from the hard disk by entering the following commands:

```
C:
CD\
C:\WIN98\SETUP
```

These commands change you to drive C:, place you in the root directory, and then run the Windows SETUP program to start the installation. From there, the menu-driven Windows installation routines guide you. If you are using a different version of Windows, merely change the directories used in the previous example to the appropriate directories for your version of Windows.

Note

If you want to create a bootable CD containing your Windows installation files, see Chapter 13, "Optical Storage." For more information about installing CD/DVD drives, see Chapter 14.

After Windows is installed, you can install any additional drivers or application programs you want. At this point, your system should be fully operational.

Installing Important Drivers

After installing the operating system, the first thing you need to do is install drivers for devices where drivers were not found on the Windows CD. This often includes things such as chipset drivers for your motherboard, drivers for newer video cards, USB 2.0 drivers, and more. Of these, the motherboard chipset drivers are the most critical and should be installed first. A CD containing these drivers should have been included with your motherboard; insert this disc and follow the prompts to install the chipset drivers. Then install other drivers, such as video, network, modem, and so on.

Disassembly/Upgrading Preparation

After you've built your system, you probably will have to open it again sometime to perform a repair or an upgrade. Before you power off the system for the last time and begin to open the case, you should learn and record several things about your computer. Often, when working on a system, you intentionally or accidentally wipe out the CMOS Setup information. Most systems use a special battery-powered CMOS clock and a data chip that is used to store the system's configuration information. If the battery is disconnected, or if certain pins are accidentally shorted, you can discharge the CMOS memory and lose the setup. The CMOS memory in most systems is used to store simple things such as how many and what type of floppy drives are connected, how much memory is in the system, and the date and time.

A critical piece of information is the hard disk–type settings. Most modern BIOS have an autodetect feature that reads the type information directly from the drive. I recommend you set the drive type to Auto, which automatically sets all the necessary parameters for you. With older BIOS you must explicitly tell the system the parameters of the attached hard disk. Therefore, you need to know the current settings for cylinders, heads, and sectors per track.

If you do not enter the correct hard disk–type information in the CMOS Setup program, you will not be able to access the data on the hard disk. I know of several people who lost some or all of their data because they did not enter the correct type information when they reconfigured their systems. If this information is incorrect, the usual results are a missing operating system error message when the systems starts and the inability to access the C: drive.

Some people think that it's possible to figure out the parameters by looking up the particular hard disk in a table. (I have included a table of popular hard disk drive parameters in the Technical Reference on the DVD-ROM. This table has proven to be useful to me time and time again.) Unfortunately, this method works only if the person who set up the system originally entered the correct parameters. I have encountered a large number of systems in which the hard disk parameters were not entered correctly; the only way to regain access to the data is to determine, and then use, the same incorrect parameters that were used originally. As you can see, no matter what, you should record the hard disk information from your setup program.

Most systems have the setup program built right into the ROM BIOS software. These built-in setup programs are activated by a key sequence usually entered during the POST. Most systems show a prompt on the screen during the POST indicating which key to press to enter the BIOS Setup.

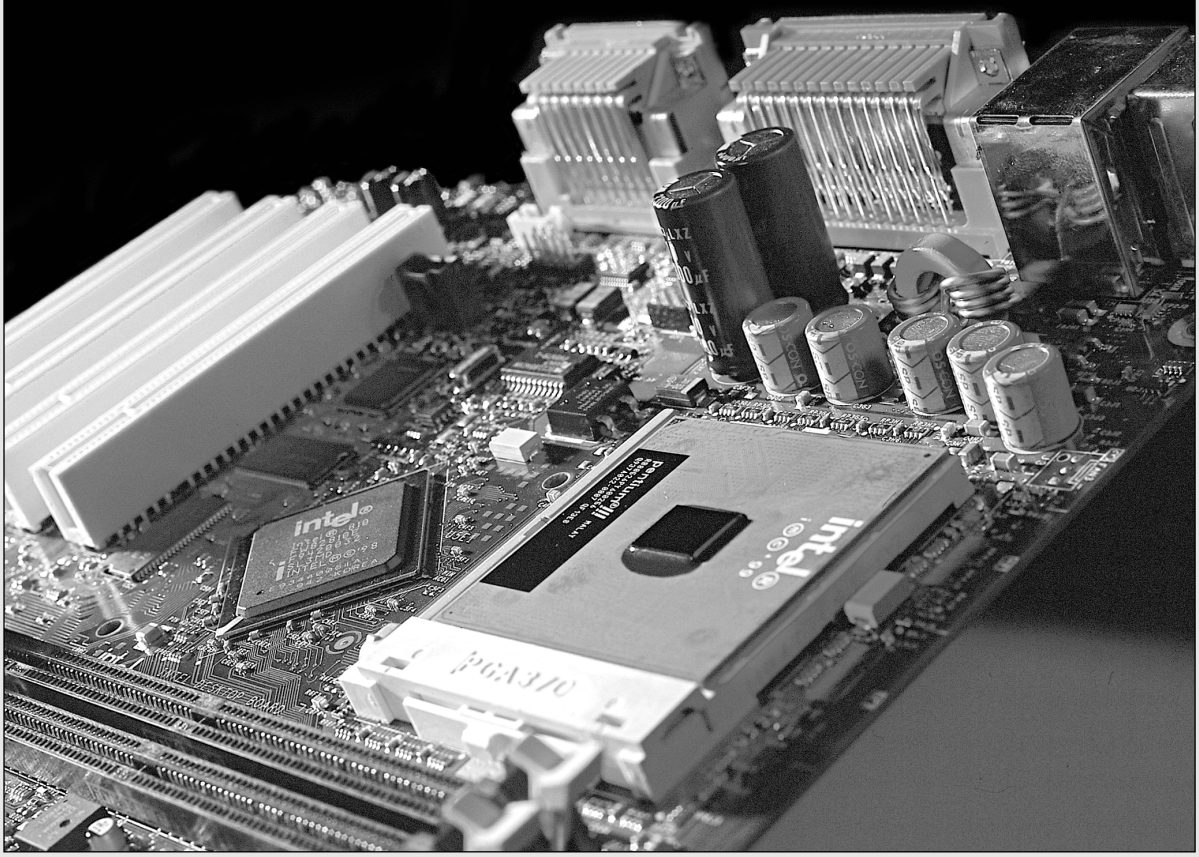
The major vendors have standardized on these following keystrokes to enter the BIOS Setup:

- *AMI BIOS.* Press Del during POST.
- *Phoenix BIOS.* Press F2 during POST.
- *Award BIOS.* Press Del or Ctrl+Alt+Esc during POST.
- *Microid Research BIOS.* Press Esc during POST.

If your system does not respond to one of these common keystroke settings, you might have to contact the manufacturer or read the system documentation to find the correct keystrokes to enter setup.

Some unique ones I have encountered are as follows:

- *IBM Aptiva/Valuepoint.* Press F1 during POST.
- *Older Phoenix BIOS.* Boot to a safe mode DOS command prompt, and then press Ctrl+Alt+Esc or Ctrl+Alt+S.
- *Compaq.* Press F10 during POST.



◀◀ See "Running or Accessing the CMOS Setup Program," p. 384.

After you're in the BIOS Setup main screen, you'll usually find a main menu allowing access to other menus and submenus offering various sections or screens. When you get the setup program running, record all the settings. The easiest way to do this is to print it. If a printer is connected, press Shift+Print Screen; a copy of the screen display will be sent to the printer. Some setup programs have several pages of information, so you should record the information on each page.

Many setup programs allow for specialized control of the particular chipset used in the motherboard. These complicated settings can take up to several screens of information—all should be recorded. Most systems return these settings to a BIOS default if the CMOS battery is removed, and you lose any customized settings you might have changed. See Chapter 5 for more information on the BIOS settings.

CHAPTER 23

PC Diagnostics, Testing, and Maintenance

No matter how well built your PC is and how well written its software, something is eventually going to go wrong, and you might not always have a support system available to resolve the problem. Diagnostic software can be vitally important to you anytime your computer malfunctions or you are in the process of upgrading a system component or especially building an entirely new system from scratch. This chapter examines the types of diagnostics software available, and particularly those utilities you might already own because they are included with common operating systems and hardware products.

You also might find that your system problems are caused by a hardware malfunction and that you must open the computer case to perform repairs. This chapter also examines the tools and testers used to upgrade and repair PCs—both the basic items every user should own and some of the more advanced devices.

Of course, the best way to deal with a problem is to prevent it from occurring in the first place. The preventive maintenance sections of this chapter describe the procedures you should perform on a regular basis to keep your system in good working order.

PC Diagnostics

This chapter describes several levels of diagnostic software that are either included with your system or available from your system manufacturer as well as third parties. The chapter describes how you can get the most from this software. It also details the various ROM BIOS audio codes and error codes and examines aftermarket diagnostics and public-domain diagnostic software.

Diagnostics Software

Several types of diagnostic software are available for PCs. Some diagnostic functions are integrated into the PC hardware or into peripheral devices, such as expansion cards, whereas others take the form of operating system utilities or separate software products. This software, some of which is included with the system when purchased, assists users in identifying many problems that can occur with a computer's components. In many cases, these programs can do most of the work in determining which PC component is defective or malfunctioning. The types of diagnostic software are as follows:

- *POST.* The power on self test operates whenever any PC is powered up (switched on). These routines are contained within the motherboard ROM as well as ROMs on expansion cards.
- *Manufacturer supplied diagnostics software.* Many of the larger manufacturers—especially high-end, name-brand manufacturers such as IBM, Compaq, Hewlett-Packard, Dell, and others—make special diagnostics software expressly designed for their systems. This manufacturer-specific software normally consists of a suite of tests that thoroughly examines the system. In some cases, these utilities are included with the system, or you can download these diagnostics from the manufacturer's online services at no charge; otherwise, you might have to purchase them. Many vendors include a limited version of one of the aftermarket packages that has been customized for use with their systems. In some older IBM and Compaq systems, the diagnostic software is installed on a special partition on the hard drive and can be accessed during startup. This was a convenient way for those system manufacturers to ensure that users always had diagnostics available.
- *Peripheral diagnostics software.* Many hardware devices ship with specialized diagnostics software designed to test their particular functions. Adaptec SCSI host adapters, for example, include diagnostic functions in the card's ROM BIOS that you can access with a keystroke (Ctrl+A) at boot time. Sound cards normally include a diagnostic program on a disk along with the drivers, which test and verify all the card's functions. Network adapters usually include a diagnostic

specific to that adapter on a disk, also normally with the drivers. Other devices or adapters also might provide a diagnostic program or disk, usually included with the drivers for the device.

- *Operating system diagnostics software.* Operating systems, such as Windows 9x/Me and Windows NT/2000/XP, include a variety of diagnostic software utilities designed to identify and monitor the performance of various components in the computer.
- *Aftermarket diagnostics software.* A number of manufacturers make general-purpose diagnostics software for PCs. This type of software is often bundled with other system maintenance and repair utilities to form a general PC software toolkit.

The Power On Self Test

When IBM first began shipping the original PC in 1981, it included safety features that had never been seen in a personal computer. These features were the power on self test (POST) and parity-checked memory. Although parity-checked or even error correcting code (ECC) memory is no longer available in most low-end chipsets, every PC still executes a POST when you turn it on. The following sections provide more detail on the POST, a series of program routines buried in the motherboard ROM-BIOS chip that tests all the main system components at power-on time. This series of routines is partially responsible for the delay when you turn on your PC; the computer executes the POST before loading the operating system.

What Is Tested?

Whenever you start up your computer, it automatically performs a series of tests that checks the primary components in your system, such as the CPU, ROM, motherboard support circuitry, memory, and major peripherals such as the expansion chassis. These tests are brief and are designed to catch hard (not intermittent) errors. The POST procedures are not very thorough compared with available disk-based diagnostics. The POST process provides error or warning messages whenever it encounters a faulty component.

Although the diagnostics performed by the system POST are not very thorough, they are the first line of defense, especially when it comes to detecting severe motherboard problems. If the POST encounters a problem severe enough to keep the system from operating properly, it halts the system boot process and generates an error message that often identifies the cause of the problem. These POST-detected problems are sometimes called *fatal errors* because they prevent the system from booting.

How Are Errors Displayed?

The POST tests normally provide three types of output messages: audio codes, onscreen text messages, and hexadecimal numeric codes that are sent to an I/O port address.

POST errors can be displayed in the following three ways:

- *Beep codes*. Heard through the speaker attached to the motherboard.
- *POST checkpoint codes*. Hexadecimal checkpoint codes sent to an I/O port address. A special card plugged into either an ISA or a PCI card slot is required to view these codes.
- *Onscreen messages*. Error messages displayed onscreen after the video adapter is initialized.

BIOS POST Beep Codes

Beep codes are used for fatal errors only, which are errors that occur so early in the process that the video card and other devices are not yet functional. Because no display is available, these codes take

the form of a series of beeps that identify the faulty component. When your computer is functioning normally, you should hear one short beep when the system starts up at the completion of the POST, although some systems (such as Compaq's) beep twice at the end of a normal POST. If a problem is detected, a different number of beeps sounds, sometimes in a combination of short and long tones.

BIOS POST Checkpoint Codes

POST checkpoint codes are hexadecimal numeric codes written by POST routines to I/O port address 80h as each major step is begun. These are often simply called *POST codes*. These POST codes can be read by only a special adapter card plugged into one of the system slots. These cards originally were designed for system manufacturers to use for burn-in testing of the motherboard. Several companies make these cards available to technicians. Micro 2000, JDR Microdevices, Data Depot, Ultra-X, and Trinitech are just a few manufacturers that market these POST cards. See the vendor list on the DVD for more information about these manufacturers.

POST checkpoint codes can be used to track the system's progress through the boot process from power-on right up to the point at which the bootstrap loader runs (when the operating system load begins). When you plug a POST code reader card into a slot, during the POST you will see two-digit hexadecimal numbers flash on the card's display. If the system stops unexpectedly or hangs, you can identify the test that was in progress during the hang from the two-digit code. This step usually helps to identify the malfunctioning component.

Most older POST reader cards plug into the 8-bit connector that is a part of the ISA or EISA bus. Many systems—even those with PCI slots—still have ISA connectors. In that case, those cards are adequate. However, the motherboards found in most newer PCs have no ISA slots at all, so obviously an ISA POST card won't work. Virtually all the companies that make POST cards also make PCI versions. Micro 2000 has a card called the Post-Probe, which has both ISA and PCI connectors on the same board. PCWiz has a similar card called the PCISA FlipPOST. Both companies also have separate Micro Channel Architecture (MCA) bus adapters that allow POST cards to work in older IBM PS/2 systems with the MCA bus.

No matter what, be sure your POST card works in a PCI slot if you are working on modern PCs. Most newer systems don't have ISA slots, and you will rarely encounter any MicroChannel slots.

Note

Listings for additional POST checkpoint codes can be found in the Technical Reference section of the DVD. Also, see Chapter 5, "BIOS," to learn more about working with your BIOS. Remember to consult your motherboard documentation for codes specific to your BIOS version. Also, the documentation included with the various POST cards covers most older as well as newer BIOS versions.

BIOS POST Onscreen Messages

Onscreen messages are brief messages that attempt to indicate a specific failure. These messages can be displayed only after the point at which the video adapter card and display have been initialized.

These different types of error messages are BIOS dependent and vary among BIOS manufacturers, and even in some cases among different BIOSes from the same manufacturer. The following sections list the codes used by the most popular ROM BIOS versions (AMI, Award, Phoenix, and IBM BIOS), but you should consult your motherboard or ROM BIOS manufacturer for the codes specific to your board and BIOS.

Most POST code cards come with documentation listing the POST checkpoint codes for various BIOS versions. If your BIOS is different from what I have listed here, consult the documentation for your BIOS or the information that came with your particular POST card.

Note

I've also included additional BIOS error messages in the Technical Reference section on the DVD included with this book.

AMI BIOS POST Error Codes

Table 23.1 AMI BIOS POST Beep Codes

Beeps	Error Message	Description
1	DRAM Refresh Failure	The memory refresh circuitry on the motherboard is defective.
2	Parity Error	A parity memory error occurred in system memory.
3	Base 64KB (First Bank) Memory Failure	A memory failure occurred in the first bank of memory.
4	System Timer Failure	A memory failure occurred in the first bank of memory, or Timer 1 on the motherboard is not functioning.
5	Processor Error	The processor on the motherboard generated an error.
6	Keyboard Controller Gate A20 Failure	The keyboard controller might be bad. The BIOS can't switch to protected mode.
7	Virtual Mode Processor Exception Interrupt Error	The processor generated an exception interrupt. The processor or motherboard might be defective.
8	Display Memory Read/Write Error	Either the system video adapter is missing or its memory is faulty.
9	ROM Checksum Error	The ROM checksum value does not match the value encoded in BIOS.
10	CMOS Shutdown Register Read/Write Error	The shutdown register for CMOS RAM failed.
11	Cache Error/L2 Cache Bad	The L2 cache is defective.
1 long, 3 short	Conventional/Extended Memory Failure	The memory is defective.
1 long, 8 short	Display/Retrace Test Failed	The video card is missing or defective.

AMI BIOS codes used by permission of American Megatrends, Inc.

Table 23.2 AMI BIOS POST Checkpoint Codes for All AMIBIOS Products with a BIOS Date of 7/15/95 or Later

POST Code	Description
D0h	The NMI is disabled. Power on delay is starting. Next, the initialization code checksum will be verified.
D1h	Initializing the DMA controller, performing the keyboard controller test, starting memory refresh, and entering 4GB flat memory mode next.
D3h	Starting memory sizing next.
D4h	Returning to real mode. Executing any OEM patches and setting the stack next.

Table 23.2 Continued

POST Code	Description
D5h	Passing control to the uncompressed code in shadow RAM at E000:0000h. The initialization code is copied to segment 0, and control will be transferred to segment 0.
D6h	Control is in segment 0. Next, checking whether Ctrl+Home was pressed and verifying the system BIOS checksum. If either Ctrl+Home was pressed or the system BIOS checksum is bad, next will go to checkpoint code E0h to perform FLASH BIOS Recovery. Otherwise, skip forward to checkpoint code 03h.
E0h	Begin FLASH BIOS Recovery. The onboard floppy controller, if available, is initialized. Next, beginning the base 512KB memory test.
E1h	Initializing the interrupt vector table next.
E2h	Initializing the DMA and interrupt controllers next.
E6h	Enabling the floppy drive controller and timer IRQs. Enabling internal cache memory.
EDh	Initializing the floppy drive.
EEh	Looking for a floppy disk in drive `A:`. Reading the first sector of the disk.
EFh	A read error occurred while reading the floppy drive in drive `A:`.
F0h	Next, searching for the `AMIBOOT.ROM` file in the root directory.
F1h	The `AMIBOOT.ROM` file is not in the root directory.
F2h	Next, reading and analyzing the floppy disk FAT to find the clusters occupied by the `AMIBOOT.ROM` file.
F3h	Next, reading the `AMIBOOT.ROM` file cluster by cluster.
F4h	The `AMIBOOT.ROM` file is not the correct size.
F5h	Next, disabling internal cache memory.
FBh	Next, detecting the type of Flash ROM.
FCh	Next, erasing the Flash ROM.
FDh	Next, programming the Flash ROM.
FFh	Flash ROM BIOS programming and recovery was successful. Next, restarting the system BIOS from the beginning.
03h	Continuation of normal boot (without Flash BIOS Recovery). The NMI is disabled. Next, checking for a soft reset or a power-on condition.
05h	The BIOS stack has been built. Next, disabling cache memory.
06h	Uncompressing the POST code next.
07h	Next, initializing the CPU and CPU data area.
08h	The CMOS checksum calculation is done next.
0Ah	The CMOS checksum calculation is done. Initializing the CMOS status register for date and time next.
0Bh	The CMOS status register is initialized. Next, performing any required initialization before the keyboard Basic Assurance Test (BAT) command is issued.
0Ch	The keyboard controller input buffer is free. Next, issuing the BAT command to the keyboard controller.
0Eh	The keyboard controller BAT command result has been verified. Next, performing any necessary initialization after the keyboard controller BAT command test.
0Fh	The initialization after the keyboard controller BAT command test is done. The keyboard command byte is written next.

Table 23.2 Continued

POST Code	Description
10h	The keyboard controller command byte is written. Next, issuing the Pin 23 and 24 blocking and unblocking command.
11h	Next, checking whether the End or Ins key was pressed during power on. Initializing CMOS RAM if the Initialize CMOS RAM in Every Boot AMIBIOS POST option was set in AMIBCP or the End key was pressed.
12h	Next, disabling DMA controllers 1 and 2 and interrupt controllers 1 and 2.
13h	The video display has been disabled. Port B has been initialized. Next, initializing the chipset.
14h	The 8254 timer test will begin next.
19h	The 8254 timer test is over. Starting the memory refresh test next.
1Ah	The memory refresh line is toggling. Checking the 15-second on/off time next.
23h	Reading the 8042 input port and disabling the MEGAKEY Green PC feature next. Making the BIOS code segment writable and performing any necessary configuration before initializing the interrupt vectors.
24h	The configuration required before interrupt vector initialization has completed. Interrupt vector initialization is about to begin.
25h	Interrupt vector initialization is done. Clearing the password if the POST DIAG switch is on.
27h	Any initialization before setting video mode will be done next.
28h	Initialization before setting the video mode is complete. Configuring the monochrome mode and color mode settings next.
2Ah	Bus initialization system, static, output devices will be done next, if present.
2Bh	Passing control to the video ROM to perform any required configuration before the video ROM test.
2Ch	All necessary processing before passing control to the video ROM is done. Looking for the video ROM next and passing control to it.
2Dh	The video ROM has returned control to BIOS POST. Performing any required processing after the video ROM has control.
2Eh	Completed post-video ROM test processing. If the EGA/VGA controller is not found, performing the display memory read/write test next.
2Fh	The EGA/VGA controller was not found. The display memory read/write test is about to begin.
30h	The display memory read/write test passed. Look for retrace checking next.
31h	The display memory read/write test or retrace checking failed. Performing the alternate display memory read/write test next.
32h	The alternate display memory read/write test passed. Looking for alternate display retrace checking next.
34h	Video display checking is over. Setting the display mode next.
37h	The display mode is set. Displaying the power-on message next.
38h	Initializing the bus input, IPL, general devices next, if present.
39h	Displaying bus initialization error messages.
3Ah	The new cursor position has been read and saved. Displaying the `Hit <DEL>` message next.
3Bh	The `Hit <DEL>` message is displayed. The protected mode memory test is about to start.
40h	Preparing the descriptor tables next.

Table 23.2 Continued

POST Code	Description
42h	The descriptor tables are prepared. Entering protected mode for the memory test next.
43h	Entered protected mode. Enabling interrupts for diagnostics mode next.
44h	Interrupts enabled if the diagnostics switch is on. Initializing data to check memory wraparound at 0:0 next.
45h	Data initialized. Checking for memory wraparound at 0:0 and finding the total system memory size next.
46h	The memory wraparound test is done. Memory size calculation has been done. Writing patterns to test memory next.
47h	The memory pattern has been written to extended memory. Writing patterns to the base 640KB memory next.
48h	Patterns written in base memory. Determining the amount of memory below 1MB next.
49h	The amount of memory below 1MB has been found and verified. Determining the amount of memory above 1MB next.
4Bh	The amount of memory above 1MB has been found and verified. Checking for a soft reset and clearing the memory below 1MB for the soft reset next. If this is a power-on situation, going to checkpoint 4Eh next.
4Ch	The memory below 1MB has been cleared via a soft reset. Clearing the memory above 1MB next.
4Dh	The memory above 1MB has been cleared via a soft reset. Saving the memory size next. Going to checkpoint 52h next.
4Eh	The memory test started, but not as the result of a soft reset. Displaying the first 64KB memory size next.
4Fh	The memory size display has started. The display is updated during the memory test. Performing the sequential and random memory test next.
50h	The memory below 1MB has been tested and initialized. Adjusting the displayed memory size for relocation and shadowing next.
51h	The memory size display was adjusted for relocation and shadowing. Testing the memory above 1MB next.
52h	The memory above 1MB has been tested and initialized. Saving the memory size information next.
53h	The memory size information and the CPU registers are saved. Entering real mode next.
54h	Shutdown was successful. The CPU is in real mode. Disabling the Gate A20 line, parity, and the NMI next.
57h	The A20 address line, parity, and the NMI are disabled. Adjusting the memory size depending on relocation and shadowing next.
58h	The memory size was adjusted for relocation and shadowing. Clearing the `Hit <DEL>` message next.
59h	The `Hit <DEL>` message is cleared. The `<WAIT...>` message is displayed. Starting the DMA and interrupt controller test next.
60h	The DMA page register test passed. Performing the DMA Controller 1 base register test next.
62h	The DMA controller 1 base register test passed. Performing the DMA controller 2 base register test next.
65h	The DMA controller 2 base register test passed. Programming DMA controllers 1 and 2 next.

Table 23.2 Continued

POST Code	Description
66h	Completed programming DMA controllers 1 and 2. Initializing the 8259 interrupt controller next.
67h	Completed 8259 interrupt controller initialization.
7Fh	Extended NMI source enabling is in progress.
80h	The keyboard test has started. Clearing the output buffer and checking for stuck keys. Issuing the keyboard reset command next.
81h	A keyboard reset error or stuck key was found. Issuing the keyboard controller interface test command next.
82h	The keyboard controller interface test completed. Writing the command byte and initializing the circular buffer next.
83h	The command byte was written, and global data initialization has completed. Checking for a locked key next.
84h	Locked key checking is over. Checking for a memory size mismatch with CMOS RAM data- next.
85h	The memory size check is done. Displaying a soft error and checking for a password or bypassing WINBIOS Setup next.
86h	The password was checked. Performing any required programming before WINBIOS Setup next.
87h	The programming before WINBIOS Setup has completed. Uncompressing the WINBIOS Setup code and executing the AMIBIOS Setup or WINBIOS Setup utility next.
88h	Returned from WINBIOS Setup and cleared the screen. Performing any necessary progra- ming after WINBIOS Setup next.
89h	The programming after WINBIOS Setup has completed. Displaying the power on screen message next.
8Bh	The first screen message has been displayed. The <WAIT...> message is displayed. Performing the PS/2 mouse check and extended BIOS data area allocation check next.
8Ch	Programming the WINBIOS Setup options next.
8Dh	The WINBIOS Setup options are programmed. Resetting the hard disk controller next.
8Fh	The hard disk controller has been reset. Configuring the floppy drive controller next.
91h	The floppy drive controller has been configured. Configuring the hard disk drive controller next.
95h	Initializing the bus option ROMs from C800h next.
96h	Initializing before passing control to the adapter ROM at C800h.
97h	Initialization before the C800h adapter ROM gains control has completed. The adapter ROM check is next.
98h	The adapter ROM had control and has now returned control to BIOS POST. Performing any required processing after the option ROM returned control.
99h	Any initialization required after the option ROM test has completed. Configuring the timer data area and printer base address next.
9Ah	Set the timer and printer base addresses. Setting the RS-232 base address next.
9Bh	Returned after setting the RS-232 base address. Performing any required initialization before the coprocessor test next.
9Ch	Required initialization before the coprocessor test is over. Initializing the coprocessor next.

Table 23.2 Continued

POST Code	Description
9Dh	Coprocessor initialized. Performing any required initialization after the coprocessor test next.
9Eh	Initialization after the coprocessor test is complete. Checking the extended keyboard, keyboard ID, and Num Lock key next. Issuing the keyboard ID command next.
A2h	Displaying any soft errors next.
A3h	The soft error display has completed. Setting the keyboard typematic rate next.
A4h	The keyboard typematic rate is set. Programming the memory wait states next.
A5h	Memory wait state programming is over. Clearing the screen and enabling parity and the NMI next.
A7h	NMI and parity enabled. Performing any initialization required before passing control to the adapter ROM at E000h next.
A8h	Initialization before passing control to the adapter ROM at E000h completed. Passing control to the adapter ROM at E000h next.
A9h	Returned from adapter ROM at E000h control. Performing any initialization required after the E000h option ROM had control next.
AAh	Initialization after E000h option ROM control has completed. Displaying the system configuration next.
ABh	Uncompressing the DMI data and executing DMI POST initialization next.
B0h	The system configuration is displayed.
B1h	Copying any code to specific areas.
00h	Code copying to specific areas is done. Passing control to INT 19h bootstrap loader routine next.

AMI BIOS codes used by permission of American Megatrends, Inc.

Award BIOS POST Error Codes

Currently, only one standard beep code exists in the Award BIOS. A single long beep followed by two short beeps indicates that a video error has occurred and that the BIOS cannot initialize the video screen to display any additional information. If multiple or continuous beeps occur with an Award BIOS, this usually indicates problems with the power supply or memory.

Table 23.3 Award BIOS POST Beep Codes

Beeps	Error Message	Description
1 long, 2 short	`Video Card Test Failure`	The video card is missing or defective. Try reseating or replacing the card.
1 long, 3 short	`Video Card Test Failure`	The video card is missing or defective. Try reseating or replacing the card.
Continuous beeps	`Memory Test Failed`	The memory modules are missing, improperly seated, or defective.

Table 23.4 Award BIOS POST Checkpoint Codes

Code	Code Type	Description
C0h	Turn Off Chipset Cache	OEM-specific cache control
01h	Processor Test 1	Processor status verification. Tests the following processor status flags: carry, zero, sign, and overflow.
02h	Processor Test 2	Read/Write/Verify all CPU registers except SS, SP, and BP with data patterns FF and 00.
03h	Initialize Chips	Disable NMI, PIE, AIE, UEI, and SQWV. Disable video, parity checking, and DMA. Reset math coprocessor. Clear all page registers, CMOS shutdown byte. Initialize timers 0, 1, and 2, including set EISA timer to a known state. Initialize DMA controllers 0 and 1. Initialize interrupt controllers 0 and 1. Initialize EISA extended registers.
04h	Test Memory Refresh Toggle	RAM must be periodically refreshed to keep the memory from decaying. This refresh function is working properly.
05h	Blank Video, Initialize Keyboard	Keyboard controller initialization.
07h	Test CMOS Interface and Battery Status	Verifies CMOS is working correctly and detects a bad battery.
Beh	Chipset Default Initialization	Program chipset registers with power-on BIOS defaults.
C1h	Memory Presence Test	OEM-specific test to size onboard memory.
C5h	Early Shadow	OEM-specific early shadow enable for fast boot.
C6h	Cache Presence Test	External cache size detection.
08h	Set Up Low Memory	Early chip set initialization. Memory presence test. OEM chipset routines. Clear low 64KB of memory. Test first 64KB memory.
09h	Early Cache Initialization	Cache initialization.
0Ah	Set Up Interrupt Vector Table	Initialize first 120 interrupt vectors with SPURIOUS_INT_HDLR and initialize INT 00h-1Fh according to INT_TBL.
0Bh	Test CMOS RAM Checksum	Test CMOS RAM checksum, if bad, or insert key pressed; load defaults.
0Ch	Initialize Video Interface	Detect type of keyboard controller (optional). Set NUM_LOCK status.
0Dh	Initialize Video Interface	Detect CPU clock. Read CMOS location 14h to find out type of video in use. Detect and initialize video adapter.
0Eh	Test Video Memory	Test video memory; write sign-on message to screen. Set up shadow RAM; enable shadow according to setup.

Table 23.4 Continued

Code	Code Type	Description
0Fh	Test DMA Controller 0	BIOS checksum test. Keyboard detect and initialization.
10h	Test DMA Controller 1	Test DMA controller 1.
11h	Test DMA Page Registers	Test DMA page registers.
14h	Test Timer Counter 2	Test 8254 timer 0 counter 2.
15h	Test 8259-1 Mask Bits	Verify 8259 channel 1 masked interrupts by alternately turning off and on the interrupt lines.
16h	Test 8259-2 Mask Bits	Verify 8259 channel 2 masked interrupts by alternately turning off and on the interrupt lines.
17h	Test Stuck 8259 Interrupt Bits	Turn off interrupts; then verify no interrupt mask register is on.
18h	Test 8259 Interrupt Functionality	Force an interrupt and verify the interrupt occurred.
19h	Test Stuck NMI	Verify NMI can be cleared.
1Ah	Display CPU Clock	Display CPU clock speed.
1Fh	Set EISA Mode	If EISA nonvolatile memory checksum is good, execute EISA initialization. If not, execute ISA tests and clear EISA mode flag. Test EISA configuration memory integrity (checksum and communication interface).
20h	Enable Slot 0	Initialize slot 0 (system board).
21h-2Fh	Enable Slots 1–15	Initialize slots 1–15.
30h	Size Base and Extended Memory	Size base memory from 256KB to 640KB and extended memory above 1MB.

Table 23.5 Award BIOS POST Onscreen Error Messages

Message	Description
`BIOS ROM checksum error - System halted`	The checksum of the BIOS code in the BIOS chip is incorrect, indicating the BIOS code might have become corrupt. Contact your system dealer to replace the BIOS.
`CMOS battery failed`	The CMOS battery is no longer functional. Contact your system dealer for a replacement battery.
`CMOS checksum error - Defaults loaded`	Checksum of CMOS is incorrect, so the system loads the default equipment configuration. A checksum error can indicate that CMOS has become corrupt. This error might have been caused by a weak battery. Check the battery and replace if necessary.

Table 23.5 Continued

Message	Description
`CPU at nnnn`	Displays the running speed of the CPU.
`Display switch is set incorrectly`	The display switch on the motherboard can be set to either monochrome or color. This message indicates the switch is set to a different setting than indicated in Setup. Determine which setting is correct, and then either turn off the system and change the jumper or enter Setup and change the VIDEO selection.
`Press ESC to skip memory test`	The user can press Esc to skip the full memory test.
`Floppy disk(s) fail`	Can't find or initialize the floppy drive controller or the drive. Make sure the controller is installed correctly. If no floppy drives are installed, be sure the Diskette Drive selection in Setup is set to `NONE` or `AUTO`.
`HARD DISK initializing. Please wait a moment`	Some hard drives require extra time to initialize.
`HARD DISK INSTALL FAILURE`	Can't find or initialize the hard drive controller or the drive. Make sure the controller is installed correctly. If no hard drives are installed, be sure the Hard Drive selection in Setup is set to `NONE`.
`Hard disk(s) diagnosis fail`	The system might run specific disk diagnostic routines. This message appears if one or more hard disks return an error when the diagnostics run.
`Keyboard error or no keyboard present`	Can't initialize the keyboard. Make sure the keyboard is attached correctly and no keys are pressed during POST. To purposely configure the system without a keyboard, set the error halt condition in Setup to `HALT ON ALL, BUT KEYBOARD`. The BIOS then ignores the missing keyboard during POST.
`Keyboard is locked out - Unlock the key`	This message usually indicates that one or more keys have been pressed during the keyboard tests. Be sure no objects are resting on the ke board.
`Memory Test:`	This message displays during a full memory test, counting down the memory areas being tested.
`Memory test fail`	If POST detects an error during memory testing, additional information appears giving specifics about the type and location of the memory error.
`Override enabled - Defaults loaded`	If the system can't boot using the current CMOS configuration, the BIOS can override the current configuration with a set of BIOS defaults designed for the most stable, minimal-performance system operations.

Table 23.5 Continued

Message	Description
`Press TAB to show POST screen`	System OEMs might replace Phoenix Technologies' AwardBIOS POST display with their own proprietary displays. Including this message in the OEM display permits the operator to switch between the OEM display and the default POST display.
`Primary master hard disk fail`	POST detects an error in the primary master IDE hard drive.
`Primary slave hard disk fail`	POST detects an error in the secondary master IDE hard drive.
`Resuming from disk, Press TAB to show POST screen`	Phoenix Technologies offers a save-to-disk feature for notebook computers. This message might appear when the operator restarts the system after a save-to-disk shutdown.
`Secondary master hard disk fail`	POST detects an error in the primary slave IDE hard drive.
`Secondary slave hard disk fail`	POST detects an error in the secondary slave IDE hard drive.

Phoenix BIOS POST Error Codes

The following beep codes are for the current version of Phoenix BIOS, version 4.0, release 6.1. Other versions have somewhat different beeps and Port 80h codes.

Table 23.6 Phoenix BIOS POST/Beep Error Codes

Code	Beeps	POST Routine Description
02h		Verify Real Mode
03h		Disable Non-Maskable Interrupt (NMI)
04h		Get CPU type
06h		Initialize system hardware
08h		Initialize chipset with initial POST values
09h		Set IN POST flag
0Ah		Initialize CPU registers
0Bh		Enable CPU cache
0Ch		Initialize caches to initial POST values
0Eh		Initialize I/O component
0Fh		Initialize the local bus IDE
10h		Initialize Power Management
11h		Load alternate registers with initial POST values
12h		Restore CPU control word during warm boot
13h		Initialize PCI Bus Mastering devices
14h		Initialize keyboard controller

Table 23.6 Continued

Code	Beeps	POST Routine Description
16h	1-2-2-3	BIOS ROM checksum
17h		Initialize cache before memory autosize
18h		8254 timer initialization
1Ah		8237 DMA controller initialization
1Ch		Reset Programmable Interrupt Controller
20h	1-3-1-1	Test DRAM refresh
22h	1-3-1-3	Test 8742 Keyboard Controller
24h		Set ES segment register to 4GB
26h		Enable A20 line
28h		Autosize DRAM
29h		Initialize POST Memory Manager
2Ah		Clear 512KB base RAM
2Ch	1-3-4-1	RAM failure on address lines
2Eh	1-3-4-3	RAM failure on data bits of low byte of memory bus
2Fh		Enable cache before system BIOS shadow
30h	1-4-1-1	RAM failure on data bits of high byte of memory bus
32h		Test CPU bus clock frequency
33h		Initialize Phoenix Dispatch Manager
36h		Warm start shutdown
38h		Shadow system BIOS ROM
3Ah		Autosize cache
3Ch		Advanced configuration of chipset registers
3Dh		Load alternative registers with CMOS values
42h		Initialize interrupt vectors
45h		POST device initialization
46h	2-1-2-3	Check ROM copyright notice
48h		Check video configuration against CMOS
49h		Initialize PCI bus and devices
4Ah		Initialize all video adapters in system
4Bh		QuietBoot start (optional)
4Ch		Shadow video BIOS ROM
4Eh		Display BIOS copyright notice
50h		Display CPU type and speed
51h		Initialize EISA board
52h		Test keyboard
54h		Set key click if enabled
58h	2-2-3-1	Test for unexpected interrupts
59h		Initialize POST display service

Table 23.6 Continued

Code	Beeps	POST Routine Description
5Ah		Display prompt `Press F2 to enter SETUP`
5Bh		Disable CPU cache
5Ch		Test RAM between 512KB and 640KB
60h		Test extended memory
62h		Test extended memory address lines
64h		Jump to `UserPatch1`
66h		Configure advanced cache registers
67h		Initialize Multiprocessor APIC
68h		Enable external and CPU caches
69h		Set up System Management Mode (SMM) area
6Ah		Display external L2 cache size
6Bh		Load custom defaults (optional)
6Ch		Display shadow-area message
6Eh		Display possible high address for UMB recovery
70h		Display error messages
72h		Check for configuration errors
76h		Check for keyboard errors
7Ch		Set up hardware interrupt vectors
7Eh		Initialize coprocessor if present
80h		Disable onboard Super I/O ports and IRQs
81h		Late POST device initialization
82h		Detect and install external RS232 ports
83h		Configure non-MCD IDE controllers
84h		Detect and install external parallel ports
85h		Initialize PC-compatible PnP ISA devices
86h		Reinitialize onboard I/O ports
87h		Configure motherboard configurable devices (optional)
88h		Initialize BIOS data area
89h		Enable Non-Maskable Interrupts (NMIs)
8Ah		Initialize extended BIOS data area
8Bh		Test and initialize PS/2 mouse
8Ch		Initialize floppy controller
8Fh		Determine number of ATA drives (optional)
90h		Initialize hard disk controllers
91h		Initialize local bus hard disk controllers
92h		Jump to `UserPatch2`
93h		Build MPTABLE for multiprocessor boards
95h		Install CD-ROM for boot

Table 23.6 Continued

Code	Beeps	POST Routine Description
96h		Clear huge ES segment register
97h		Fix up multiprocessor table
98h	1-2	Search for option ROMs (one long, two short beeps on checksum failure)
99h		Check for SMART drive (optional)
9Ah		Shadow option ROMs
9Ch		Set up Power Management
9Dh		Initialize security engine (optional)
9Eh		Enable hardware interrupts
9Fh		Determine number of ATA and SCSI drives
A0h		Set time of day
A2h		Check key lock
A4h		Initialize Typematic rate
A8h		Erase F2 prompt
AAh		Scan for F2 keystroke
ACh		Enter Setup
AEh		Clear Boot flag
B0h		Check for errors
B2h		POST done; prepare to boot operating system
B4h	1	One short beep before boot
B5h		Terminate QuietBoot (optional)
B6h		Check password (optional)
B9h		Prepare boot
BAh		Initialize DMI parameters
BBh		Initialize PnP option ROMs
BCh		Clear parity checkers
BDh		Display MultiBoot menu
BEh		Clear screen (optional)
BFh		Check virus and backup reminders
C0h		Try to boot with INT 19
C1h		Initialize POST Error Manager (PEM)
C2h		Initialize error logging
C3h		Initialize error display function
C4h		Initialize system error handler
C5h		PnPnd dual CMOS (optional)
C6h		Initialize notebook docking (optional)
C7h		Initialize notebook docking late
C8h		Force check (optional)
C9h		Extended checksum (optional)

Table 23.6 Continued

Code	Beeps	POST Routine Description
D2h		Unknown interrupt
E0h		Initialize the chipset
E1h		Initialize the bridge
E2h		Initialize the CPU
E3h		Initialize system timer
E4h		Initialize system I/O
E5h		Check force recovery boot
E6h		Checksum BIOS ROM
E7h		Go to BIOS
E8h		Set Huge Segment
E9h		Initialize Multiprocessor
EAh		Initialize OEM special code
EBh		Initialize PIC and DMA
ECh		Initialize memory type
EDh		Initialize memory size
EEh		Shadow boot block
EFh		System memory test
F0h		Initialize interrupt vectors
F1h		Initialize runtime clock
F2h		Initialize video
F3h		Initialize System Management Mode
F4h	1	Output one beep before boot
F5h		Boot to Mini DOS
F6h		Clear Huge Segment
F7h		Boot to Full DOS

IBM BIOS POST Error Codes

Table 23.7 IBM BIOS Beep Codes

Audio Code	Sound Graph	Description
1 short beep	•	Normal POST—system okay
2 short beeps	••	POST error—error code on display
No beep		Power supply, system board
Continuous beep	————	Power supply, system board
Repeating short beeps	•••• ••	Power supply, system board
1 long, 1 short beep	-•	System board

Table 23.7 Continued

Audio Code	Sound Graph	Description
1 long, 2 short beeps	-••	Video adapter (MDA/CGA)
1 long, 3 short beeps	-•••	Video adapter (EGA/VGA)
3 long beeps	- - -	3270 keyboard card

IBM BIOS beep and Alphanumeric error codes used by permission of IBM.

Table 23.8 IBM BIOS POST/Diagnostics Display Error Codes

Code	Description
1xx	System board errors
2xx	Memory (RAM) errors
3xx	Keyboard errors
4xx	Monochrome Display Adapter (MDA) errors
4xx	PS/2 system board parallel port errors
5xx	Color Graphics Adapter (CGA) errors
6xx	Floppy drive/controller errors
7xx	Math Coprocessor errors
9xx	Parallel printer adapter errors
10xx	Alternate parallel printer adapter errors
11xx	Primary Async Communications (Serial COM1:) errors
12xx	Alternate Async Communications (Serial COM2:, COM3:, and COM4:) errors
13xx	Game control adapter errors
14xx	Matrix printer errors
15xx	Synchronous Data Link Control (SDLC) Communications adapter errors
16xx	Display Station Emulation Adapter (DSEA) errors (5520, 525x)
17xx	ST-506/412 fixed disk and controller errors
18xx	I/O expansion unit errors
19xx	3270 PC attachment card errors
20xx	Binary Synchronous Communications (BSC) adapter errors
21xx	Alternate Binary Synchronous Communications (BSC) adapter errors
22xx	Cluster adapter errors
23xx	Plasma monitor adapter errors
24xx	Enhanced graphics adapter (EGA) or video graphics array (VGA) errors
25xx	Alternate Enhanced Graphics Adapter (EGA) errors
26xx	XT or AT/370 370-M (memory) and 370-P (processor) adapter errors
27xx	XT or AT/370 3277-EM (emulation) adapter errors
28xx	3278/79 emulation adapter or 3270 connection adapter errors
29xx	Color/graphics printer errors
30xx	Primary PC network adapter errors

Table 23.8 Continued

Code	Description
31xx	Secondary PC network adapter errors
32xx	3270 PC or AT display and programmed symbols adapter errors
33xx	Compact printer errors
35xx	Enhanced display station emulation adapter (EDSEA) errors
36xx	General-purpose interface bus (GPIB) adapter errors
37xx	System board SCSI controller errors
38xx	Data acquisition adapter errors
39xx	Professional graphics adapter (PGA) errors
44xx	5278 display attachment unit and 5279 display errors
45xx	IEEE interface adapter (IEEE-488) errors
46xx	A real-time interface coprocessor (ARTIC) multiport/2 adapter errors
48xx	Internal modem errors
49xx	Alternate internal modem errors
50xx	PC convertible LCD errors
51xx	PC convertible portable printer errors
56xx	Financial communication system errors
70xx	Phoenix BIOS/chipset unique error codes
71xx	Voice communications adapter (VCA) errors
73xx	3 1/2" external disk drive errors
74xx	IBM PS/2 display adapter (VGA Card) errors
74xx	8514/A display adapter errors
76xx	4216 PagePrinter adapter errors
84xx	PS/2 speech adapter errors
85xx	2MB XMA memory adapter or XMA adapter/A errors
86xx	PS/2 pointing device (mouse) errors
89xx	Musical Instrument Digital Interface (MIDI) adapter errors
91xx	IBM 3363 write-once read multiple (WORM) optical drive/adapter errors
96xx	SCSI adapter with cache (32-bit) errors
100xx	Multiprotocol adapter/A errors
101xx	300/1200bps internal modem/A errors
104xx	ESDI or MCA IDE fixed disk or adapter errors
107xx	5 1/4" external disk drive or adapter errors
112xx	SCSI adapter (16-bit without cache) errors
113xx	System board SCSI adapter (16-bit) errors
129xx	Processor complex (CPU board) errors
149xx	P70/P75 plasma display and adapter errors
152xx	XGA display adapter/A errors
164xx	120MB internal tape drive errors

Table 23.8 Continued

Code	Description
165xx	6157 streaming tape drive or tape attachment adapter errors
166xx	Primary Token-Ring network adapter errors
167xx	Alternate Token-Ring network adapter errors
180xx	PS/2 wizard adapter errors
185xx	DBCS Japanese display adapter/A errors
194xx	80286 memory-expansion option memory-module errors
200xx	Image adapter/A errors
208xx	Unknown SCSI device errors
209xx	SCSI removable disk errors
210xx	SCSI fixed disk errors
211xx	SCSI tape drive errors
212xx	SCSI printer errors
213xx	SCSI processor errors
214xx	SCSI write-once read multiple (WORM) drive errors
215xx	SCSI CD-ROM drive errors
216xx	SCSI scanner errors
217xx	SCSI magneto optical drive errors
218xx	SCSI jukebox changer errors
219xx	SCSI communications errors
243xxxx	XGA-2 adapter/A errors
I998xxxx	Dynamic configuration select (DCS) information codes
I99900xx	Initial microcode load (IML) error
I99903xx	No bootable device, initial program load (IPL) errors
I99904xx	IML-to-system mismatch
I99906xx	IML (boot) errors

IBM BIOS beep and alphanumeric error codes used by permission of IBM.

POST Memory Count

On some PCs, the POST also displays the results of its system memory test on the monitor. The last number displayed is the amount of memory that tested successfully. For example, a system might display the following message:

```
32768 KB OK
```

The number displayed by the memory test should agree with the total amount of memory installed on the system motherboard. Some older systems display a slightly lower total because they deduct part or all of the 384KB of UMA (upper memory area) from the count. On old systems that use expanded memory cards, the memory on the card is not tested by the POST and does not count in the numbers reported. Also, this memory test is performed before any system software loads, so many memory managers or device drivers you might have installed do not affect the results of the test. If the POST memory test stops short of the expected total, the number displayed can indicate how far into the system memory array a memory error lies. This number can help you identify the exact module that is at fault and can be a valuable troubleshooting aid in itself.

Hardware Diagnostics

Many types of diagnostic software are used with specific hardware products. This software can be integrated into the hardware, included with the hardware purchase, or sold as a separate product. The following sections examine several types of hardware-specific diagnostics.

Note

IBM included specialized diagnostic software for its older PS/2 systems. For more information on this software, see "IBM Diagnostics," in the sixth edition of *Upgrading and Repairing PCs* on the DVD-ROM included with this book.

SCSI Diagnostics

Unlike the IDE drive support that is built into the system BIOS of virtually every PC, SCSI is an add-on technology, and most SCSI host adapters contain their own BIOS that enables you to boot the system from a SCSI hard drive. In some cases, the SCSI BIOS also contains configuration software for the adapter's various features, and diagnostics software as well.

The most popular manufacturer of SCSI host adapters is Adaptec, and most of its host adapters contain these features. An Adaptec SCSI adapter normally includes a BIOS that can be enabled or disabled. When the BIOS is activated, you see a message on the monitor as the system boots, identifying the model of the adapter and the revision number of the BIOS. The message also instructs you to press Ctrl+A to access what Adaptec calls its SCSISelect utility.

The SCSISelect utility identifies the Adaptec host adapters installed in the system and, if more than one exists, enables you to choose the adapter you want to work with by selecting its port address. After you do this, you are presented with a menu of the functions built into the adapter's BIOS. Every adapter BIOS contains a configuration program and a SCSI Disk Utilities feature that scans the SCSI bus, identifying the devices connected to it. For each hard disk drive connected to the bus, you can perform a low-level disk format or scan the disk for defects, remapping any bad blocks that are found.

For SCSI adapters that use direct memory access (DMA), a Host Adapter Diagnostics feature is also available, which tests the communication between the adapter and the main system memory array by performing a series of DMA transfers. If this test fails, you are instructed how to configure the adapter to use a lower DMA transfer rate.

Network Interface Diagnostics

As with SCSI adapters, many network interface adapters are equipped with their own diagnostics, designed to test their own specialized functions. The EZSTART program included with all SMC network interface cards, for example, contains two adapter test modes. The Basic mode performs the following internal tests on the SMC8000 adapter:

- Bus Interface Controller test
- LAN Address ROM test
- Network Interface Controller test
- RAM test
- ROM test
- Interrupt Generation
- Loopback test

The Two Node test sequence requires that you have another node installed on the same network with an SMC adapter. By running the EZSTART software on both computers, you can configure one adapter as the Responder and the other as the Initiator. The Initiator transmits test messages to the Responder, which echoes the same messages back again. If the adapters and network are functioning properly, the messages should return to the Initiator system in exactly the same form as they were transmitted.

Other network adapters have similar testing capabilities, although the names of the tests might not be exactly the same. The software for the 3Com 3C509B adapter, for example, performs the following tests:

- Register Access test
- EEPROM Vital Data test
- EEPROM Configurable Data test
- FIFO Loopback test
- Interrupt test
- Ethernet Core Loopback test
- Encoder/Decoder Loopback test
- Echo Exchange test (requires two adapters on the same network)

Both the SMC and 3Com diagnostics programs are integrated into the software you use to configure the hardware resources used by the adapters and their other features. The software is not integrated into the hardware; it takes the form of a separate program that ships with the devices and that you also can download free of charge from the manufacturers' respective Web sites.

General-Purpose Diagnostics Programs

A large number of professional third-party diagnostics programs are available for PC systems. These are commercial programs that are used by technicians to perform testing of new systems (often called burn-in testing) or testing of existing systems either in the shop or in the field.

Most of the commercial PC diagnostics can test all your PC's key components. In addition, specific programs are available to test memory, floppy drives, hard disks, video adapters, and most other areas of the system. Some of the programs I recommend most highly include

- *AMIDiag Suite.* `www.ami.com`
- *MicroScope.* `www.micro2000.com`

Tip

Before trying a commercial diagnostic program to solve your problem, look in your operating system. Most operating systems today provide at least some of the diagnostic functions that diagnostic programs do. You might be able to save some time and money.

Unfortunately, no clear leader exists in the area of diagnostic software. Each program has unique advantages, and as a result, no program is universally better than another. When deciding which diagnostic programs, if any, to include in your arsenal, look for the features you need.

One of the most popular is the AMIDIAG Suite from AMI. This program runs on virtually any PC and tests most of the hardware in the system.

Note

The DVD included with this book contains a breakdown of some of the PC diagnostics software available today. See the Technical Reference section of the DVD.

Operating System Diagnostics

In many cases, it might not be necessary to purchase third-party diagnostic software because your operating system has all the diagnostic tools you need. Windows 9x/Me and NT/2000/XP include a large selection of programs that enable you to view, monitor, and troubleshoot the hardware in your system.

Note

The DVD included with this book contains a breakdown of some of the operating-system–diagnostics software available today. See the Technical Reference section of the DVD.

The Hardware Boot Process

The term *boot* comes from the word bootstrap and describes the method by which the PC becomes operational. Just as you pull on a large boot by the small strap attached to the back, a PC loads a large operating system by first loading a small program that can then pull the operating system into memory. The chain of events begins with the application of power and finally results in a fully functional computer system with software loaded and running. Each event is triggered by the event before it and initiates the event after it.

Tracing the system boot process might help you find the location of a problem if you examine the error messages the system displays when the problem occurs. If you see an error message that is displayed by only a particular program, you can be sure the program in question was at least loaded and partially running. Combine this information with the knowledge of the boot sequence, and you can at least tell how far the system's startup procedure had progressed before the problem occurred. You usually should look at whichever files or disk areas were being accessed during the failure in the boot process. Error messages displayed during the boot process and those displayed during normal system operation can be hard to decipher. However, the first step in decoding an error message is knowing where the message came from—which program actually generated or displayed it. The following programs are capable of displaying error messages during the boot process:

OS Independent:

- Motherboard ROM BIOS
- Adapter card ROM BIOS extensions
- Master (partition) boot record
- Volume boot record

OS Dependent:

- System files (`IO.SYS/IBMBIO.COM` and `MSDOS.SYS/IBMDOS.COM`)
- Device drivers (loaded through `CONFIG.SYS` or the Win Registry `SYSTEM.DAT`)
- Shell program (`COMMAND.COM` in DOS)
- Programs run by `AUTOEXEC.BAT`, the Windows Startup group, and the Registry
- Windows (`WIN.COM`)

The first portion of the startup sequence is *operating system independent*, which means these steps are the same for all PCs no matter which operating system is installed. The latter portion of the boot sequence is *operating system dependent*, which means those steps can vary depending on which operating system is installed or being loaded. The following section examines the operating-system-independent startup sequence and provides a detailed account of many of the error messages that might occur during this process.

The Boot Process: Operating System Independent

If you have a problem with your system during startup and can determine where in this sequence of events your system has stalled, you know which events have occurred and probably can eliminate each of them as a cause of the problem. The following steps occur in a typical system startup regardless of which operating system you are loading:

1. You switch on electrical power to the system.
2. The power supply performs a self-test (known as the POST). When all voltages and current levels are acceptable, the supply indicates that the power is stable and sends the Power_Good signal to the motherboard. The time from switch-on to Power_Good is normally between .1 and .5 seconds.
3. The microprocessor timer chip receives the Power_Good signal, which causes it to stop generating a reset signal to the microprocessor.

◀◀ See "The Power_Good Signal," p. 1158.

4. The microprocessor begins executing the ROM BIOS code, starting at memory address FFFF:0000. Because this location is only 16 bytes from the very end of the available ROM space, it contains a JMP (jump) instruction to the actual ROM BIOS starting address.

◀◀ See "Motherboard BIOS," p. 359.

5. The ROM BIOS performs a test of the central hardware to verify basic system functionality. Any errors that occur are indicated by audio "beep" codes because the video system has not yet been initialized. If the BIOS is Plug and Play (PnP), the following steps are executed; if not, skip to step 10.
6. The Plug and Play BIOS checks nonvolatile random access memory (RAM) for input/output (I/O) port addresses, interrupt request lines (IRQs), direct memory access (DMA) channels, and other settings necessary to configure PnP devices on the computer.
7. All Plug and Play devices found by the Plug and Play BIOS are disabled.
8. A map of used and unused resources is created.
9. The Plug and Play devices are configured and reenabled, one at a time. If your computer does not have a Plug and Play BIOS, PnP devices are initialized using their default settings. These devices can be reconfigured dynamically when Windows starts. At that point, Windows queries the Plug and Play BIOS for device information and then queries each Plug and Play device for its configuration.
10. The BIOS performs a video ROM scan of memory locations C000:0000–C780:0000 looking for video adapter ROM BIOS programs contained on a video adapter found either on a card plugged into a slot or integrated into the motherboard. If the scan locates a video ROM BIOS, it is tested by a checksum procedure. If the video BIOS passes the checksum test, the ROM is executed; then the video ROM code initializes the video adapter and a cursor appears onscreen. If the checksum test fails, the following message appears:

```
C000 ROM Error
```

11. If the BIOS finds no video adapter ROM, it uses the motherboard ROM video drivers to initialize the video display hardware, and a cursor appears onscreen.
12. The motherboard ROM BIOS scans memory locations C800:0000–DF80:0000 in 2KB increments for any other ROMs located on any other adapter cards (such as SCSI adapters). If any ROMs are found, they are checksum-tested and executed. These adapter ROMs can alter existing BIOS routines and establish new ones.
13. Failure of a checksum test for any of these ROM modules causes this message to appear:

    ```
    XXXX ROM Error
    ```

    where the address *XXXX* indicates the segment address of the failed ROM module.
14. The ROM BIOS checks the word value at memory location 0000:0472 to see whether this start is a cold start or a warm start. A word value of 1234h in this location is a flag that indicates a warm start, which causes the BIOS to skip the memory test portion of the POST. Any other word value in this location indicates a cold start, and the BIOS performs the full POST procedure. Some system BIOSes let you control various aspects of the POST procedure, making it possible to skip the memory test, for example, which can be lengthy on a system with a lot of RAM.
15. If this is a cold start, the full POST executes; if this is a warm start, a mini-POST executes, minus the RAM test. Any errors found during the POST are reported by a combination of audio and displayed error messages. Successful completion of the POST is indicated by a single beep (with the exception of some Compaq computers, which beep twice).
16. The ROM BIOS searches for a boot record at cylinder 0, head 0, sector 1 (the very first sector) on the default boot drive. At one time, the default boot drive was always the first floppy disk, or A: drive. However, the BIOSes on today's systems often enable you to select the default boot device and the order in which the BIOS will look for other devices to boot from if necessary, using a floppy disk, hard disk, or even a CD-ROM drive in any order you choose. This sector is loaded into memory at 0000:7C00 and tested.

    If a disk is in the drive but the sector can't be read, or if no disk is present, the BIOS continues with step 19.

Tip

If you do want to boot from a CD-ROM, be sure the CD-ROM drive is specified before the hard disk in the boot devices menu in your BIOS setup. To ensure that you can boot from an emergency CD or floppy disk, I recommend setting the CD-ROM as the first and the floppy drive as the second boot device. A hard disk containing your operating system should be the third device in the boot device list. This enables you to always be ready for an emergency. So long as you do not boot with a CD or floppy loaded, the BIOS bypasses both the CD and floppy disk drives and boots from the hard drive.

Note that not all operating system CDs are bootable. Windows 95 CDs are not bootable; however, with Windows 98, Microsoft made the operating system CD bootable, but only for OEM (original equipment manufacturer) versions. This does not extend to retail versions of these Windows CDs. Windows NT 4.0 and later, including Windows 2000 and XP, are shipped on bootable CDs. See Chapter 13, "Optical Storage," for information on how to make a bootable CD.

17. If you are booting from a floppy disk and the first byte of the volume boot record is less than 06h, or if the first byte is greater than or equal to 06h and the first nine words contain the same data pattern, this error message appears and the system stops:

    ```
    602-Diskette Boot Record Error
    ```

18. If the volume boot record can't find or load the system files, or if a problem was encountered loading them, one of the following messages appears:

```
Non-System disk or disk error
Replace and strike any key when ready
```

```
Non-System disk or disk error
Replace and press any key when ready
```

```
Invalid system disk_
Replace the disk, and then press any key
```

```
Disk Boot failure
```

```
Disk I/O Error
```

All these messages originate in the volume boot record (VBR) and relate to VBR or system file problems.

19. If no boot record can be read from drive A: (such as when no disk is in the drive), the BIOS then looks for a master boot record (MBR) at cylinder 0, head 0, sector 1 (the very first sector) of the first hard disk. If this sector is found, it is loaded into memory address 0000:7C00 and tested for a signature.

20. If the last two (signature) bytes of the MBR are not equal to 55AAh, software interrupt 18h (Int 18h) is invoked on most systems.

This causes the BIOS to display an error message that can vary for different BIOS manufacturers, but which is often similar to one of the following messages, depending on which BIOS you have:

IBM BIOS:

```
The IBM Personal Computer Basic_
Version C1.10 Copyright IBM Corp 1981
62940 Bytes free_
Ok_
```

Most IBM computers since 1987 display a strange character graphic depicting the front of a floppy drive, a 3 1/2" disk, and arrows prompting you to insert a disk in the drive and press the F1 key to proceed.

AMI BIOS:

```
NO ROM BASIC - SYSTEM HALTED
```

Compaq BIOS:

```
Non-System disk or disk error
replace and strike any key when ready
```

Award BIOS:

```
DISK BOOT FAILURE, INSERT SYSTEM DISK AND PRESS ENTER
```

Phoenix BIOS:

```
No boot device available -
strike F1 to retry boot, F2 for setup utility
```

or

```
No boot sector on fixed disk -
strike F1 to retry boot, F2 for setup utility
```

Although the messages vary from BIOS to BIOS, the cause for each relates to specific bytes in the MBR, which is the first sector of a hard disk at the physical location cylinder 0, head 0, sector 1.

The problem involves a disk that either has never been partitioned or has had the Master Boot Sector corrupted. During the boot process, the BIOS checks the last two bytes in the MBR (first sector of the drive) for a signature value of 55AAh. If the last two bytes are not 55AAh, an Interrupt 18h is invoked, which calls the subroutine that displays one of the error messages just shown, which basically instructs the user to insert a bootable floppy to proceed.

The MBR (including the signature bytes) is written to the hard disk by the DOS FDISK program. Immediately after a hard disk is low-level formatted, all the sectors are initialized with a pattern of bytes, and the first sector does not contain the 55AAh signature. In other words, these ROM error messages are exactly what you see if you attempt to boot from a hard disk that has been freshly low-level formatted, but has not yet been partitioned.

21. The MBR searches its built-in partition table entries for a boot indicator byte marking an active partition entry.

22. If none of the partitions are marked active (bootable), the BIOS invokes software interrupt 18h, which displays an error message (refer to step 20).

23. If any boot indicator byte in the MBR partition table is invalid, or if more than one indicates an active partition, the following message is displayed and the system stops:

```
Invalid partition table
```

24. If an active partition is found in the MBR, the partition boot record from the active partition is loaded and tested.

25. If the partition boot record can't be read successfully from the active partition within five retries because of read errors, the following message is displayed and the system stops:

```
Error loading operating system
```

26. The hard disk's partition boot record is tested for a signature. If it does not contain a valid signature of 55AAh as the last two bytes in the sector, the following message is displayed and the system stops:

```
Missing operating system
```

27. The volume boot record is executed as a program. This program looks for and loads the operating system kernel or system files. If the volume boot record can't find or load the system files, or if a problem was encountered loading them, one of the following messages appears:

```
Non-System disk or disk error
Replace and strike any key when ready
```

```
Non-System disk or disk error
Replace and press any key when ready
```

```
Invalid system disk_
Replace the disk, and then press any key
```

```
Disk Boot failure
```

```
Disk I/O Error
```

All these messages originate in the volume boot record (VBR) and relate to VBR or system file problems.

From this point forward, what happens depends on which operating system you have. The operating-system-dependent boot procedures are discussed in the next several sections.

The DOS Boot Process

1. The initial system file (called IO.SYS or IBMBIO.COM) is executed.
2. The initialization code in IO.SYS/IBMBIO.COM copies itself into the highest region of contiguous DOS memory and transfers control to the copy. The initialization code copy then relocates MSDOS.SYS over the portion of IO.SYS in low memory that contains the initialization code because the initialization code no longer needs to be in that location.
3. The initialization code executes MSDOS.SYS (or IBMDOS.COM), which initializes the base device drivers, determines equipment status, resets the disk system, resets and initializes attached devices, and sets the system default parameters.
4. The full DOS file system is active, and control is returned to the IO.SYS initialization code.
5. The IO.SYS initialization code reads the CONFIG.SYS file multiple times.
6. When loading CONFIG.SYS, the DEVICE statements are first processed in the order in which they appear. Any device driver files named in those DEVICE statements are loaded and executed. Then, any INSTALL statements are processed in the order in which they appear; the programs named are loaded and executed. The SHELL statement is processed and loads the specified command processor with the specified parameters. If the CONFIG.SYS file contains no SHELL statement, the default \COMMAND.COM processor is loaded with default parameters. Loading the command processor overwrites the initialization code in memory (because the job of the initialization code is finished).

   During the final reads of CONFIG.SYS, all the remaining statements are read and processed in a predetermined order. Thus, the order of appearance for statements other than DEVICE, INSTALL, and SHELL in CONFIG.SYS is of no significance.
7. If AUTOEXEC.BAT is present, COMMAND.COM loads and runs AUTOEXEC.BAT. After the commands in AUTOEXEC.BAT have been executed, the DOS prompt appears (unless AUTOEXEC.BAT calls an application program or shell of some kind, in which case the user might operate the system without ever seeing a DOS prompt).
8. If no AUTOEXEC.BAT file is present, COMMAND.COM executes the internal DATE and TIME commands, displays a copyright message, and displays the DOS prompt.

Some minor variations from this scenario are possible, such as those introduced by other ROM programs in the various adapters that might be plugged into an expansion slot. Also, depending on the exact ROM BIOS programs involved, some of the error messages and sequences can vary. Generally, however, a computer follows this chain of events while "coming to life."

You can modify the system startup procedures by altering the CONFIG.SYS and AUTOEXEC.BAT files. These files control the configuration of DOS and allow special startup programs to be executed every time the system starts.

The Windows 9x/Me Boot Process

Knowing exactly how Windows 9x and Millennium Edition (Me) load and start can be helpful when troubleshooting startup problems. The Windows 9x boot process can be broken into three phases:

- The IO.SYS file is loaded and run. (Windows 9x's IO.SYS combines the functions of DOS's IO.SYS and MSDOS.SYS.)
- Real-mode configuration takes place.
- The WIN.COM file is loaded and run.

Phase 1—Loading and Running the IO.SYS File

1. The initialization code initializes the base device drivers, determines equipment status, resets the disk system, resets and initializes attached devices, and sets the system default parameters.
2. The file system is activated, and control is returned to the IO.SYS initialization code.
3. The `Starting Windows` message is displayed for *<n>* seconds, or until you press a Windows function key. The amount of time the message is displayed is determined by the `BootDelay=<n>` line in the MSDOS.SYS file; the default is 2 seconds.
4. The IO.SYS initialization code reads the MSDOS.SYS configuration file. If you have multiple hardware profiles, you receive the following message and must choose a hardware configuration to use:

   ```
   Windows cannot determine what configuration your computer is in.
   ```

5. The LOGO.SYS file is loaded and displays a startup image onscreen.
6. If the DRVSPACE.INI or DBLSPACE.INI file exists, it is loaded into memory. IO.SYS also automatically loads HIMEM.SYS, IFSHLP.SYS, and SETVER.EXE.
7. The IO.SYS file checks the system Registry files (SYSTEM.DAT and USER.DAT) for valid data.
8. IO.SYS opens the SYSTEM.DAT file. If the SYSTEM.DAT file is not found, the SYSTEM.DA0 file is used for startup. If Windows 9x/Me starts successfully, the SYSTEM.DA0 file is copied to the SYSTEM.DAT file.
9. The DBLBUFF.SYS file is loaded if the `DoubleBuffer=1` is in the MSDOS.SYS file or if double buffering is enabled under the following Registry key:

   ```
   HKLM\System\CurrentControlSet\Control\WinBoot\DoubleBuffer
   ```

Note

Windows 9x Setup automatically enables double buffering if it detects that it is required.

10. If you have multiple hardware profiles, the hardware profile you chose is loaded from the Registry.
11. In Windows 9x/Me, the system looks in the Registry's `Hkey_Local_Machine\System\CurrentControlSet` key to load the device drivers and other parameters specified there before executing the CONFIG.SYS file.

Phase 2—Real-Mode Configuration

Some older hardware devices and programs require that drivers or files be loaded in real mode (16-bit mode) for them to work properly. To ensure backward compatibility, Windows 9x processes the CONFIG.SYS and AUTOEXEC.BAT files if they exist:

1. The CONFIG.SYS file is read if it exists, and the statements within are processed, including the loading of drivers into memory. If the CONFIG.SYS file does not exist, the IO.SYS file loads the following required drivers:

   ```
   IFSHLP.SYS

   HIMEM.SYS

   SETVER.EXE
   ```

   IO.SYS obtains the location of these files from the `WinBootDir=` line of the MSDOS.SYS file and must be on the hard disk.

2. Windows reserves all global upper memory blocks (UMBs) for Windows 9x operating system use or for expanded memory support (EMS).
3. The `AUTOEXEC.BAT` file is processed if present, and any terminate-and-stay resident (TSR) programs listed within are loaded into memory.

Phase 3—Loading and Running the `WIN.COM` File

1. `WIN.COM` is loaded and run.
2. The `WIN.COM` file accesses the `VMM32.VXD` file. If enough RAM is available, the `VMM32.VXD` file loads into memory; otherwise, it is accessed from the hard disk (resulting in a slower startup time).
3. The real-mode virtual device driver loader checks for duplicate virtual device drivers (VxDs) in the `WINDOWS\SYSTEM\VMM32` folder and the `VMM32.VXD` file. If a VxD exists in both the `WINDOWS\SYSTEM\VMM32` folder and the `VMM32.VXD` file, the duplicate VxD is "marked" in the `VMM32.VXD` file so that it is not loaded.
4. VxDs not already loaded by the `VMM32.VXD` file are loaded from the `[386 Enh]` section of the `WINDOWS\SYSTEM.INI` file.

Required VxDs

Some VxDs are required for Windows to run properly. These required VxDs are loaded automatically and do not require a Registry entry. Windows 9x requires the following VxDs:

*BIOSXLAT	*CONFIGMG	*DYNAPAGE
*DOSMGR	*EBIOS	*IFSMGR
*INT13	*IOS	*PAGESWAP
*SHELL	*V86MMGR	*VCD
*VCACHE	*VCOMM	*VCOND
*VDD	*VDMAD	*VFAT
*VKD	*VMCPD	*VPICD
*VTD	*VTDAPI	*VWIN32
*VXDLDR		

5. The real-mode virtual device driver loader checks that all required VxDs loaded successfully. If not, it attempts to load the drivers again.
6. After the real-mode virtual device driver loading is logged, driver initialization occurs. If any VxDs require real-mode initialization, they begin their processes in real mode.
7. VMM32 switches the computer's processor from real mode to protected mode.
8. A three-phase VxD initialization process occurs in which the drivers are loaded according to their InitDevice instead of the order in which they are loaded into memory.
9. After all the VxDs are loaded, the `KRNL32.DLL`, `GDI.EXE`, `USER.EXE`, and `EXPLORER.EXE` (the default Windows 9x GUI shell) files are loaded.
10. If a network is specified, load the network environment and multiuser profiles. The user is prompted to log on to the network installed. Windows 9x/Me enables multiple users to save their custom desktop settings. When a user logs on to Windows, her desktop settings are loaded from the Registry. If the user does not log on, the desktop configuration uses a default desktop.

11. Programs in the StartUp group and the `RunOnce` Registry key are run during the last phase of the startup process. After each program in the `RunOnce` Registry key is started, the program is removed from the key.

Windows NT/2000/XP Startup

When you start a Windows NT, 2000, or XP system (which are all based on the same set of integral code), the boot process is different from that of a DOS or Windows 9.x/Me system. Instead of the `IO.SYS` and `MSDOS.SYS` files used by 9x/Me, Windows NT/2000/XP use an OS loader program called Ntldr.

The basic Windows NT/2000/XP startup process is described in the following step-by-step procedures:

1. *The partition boot sector loads Ntldr (NT Loader).* It then switches the processor to protected mode, starts the file system, and reads the contents of `Boot.ini`. The information in `Boot.ini` determines the startup options and initial boot menu selections (dual-booting, for example). If dual-booting is enabled, and a non-NT/2000/XP OS is chosen, `Bootsec.dos` is loaded. If SCSI drives are present, `Ntbootdd.sys` is loaded, which contains the SCSI boot drivers.
2. *`Ntdetect.com` gathers hardware configuration data and passes this information to Ntldr.* If more than one hardware profile exists, Windows uses the correct one for the current configuration. If the ROM BIOS is ACPI compliant, Windows uses ACPI to enumerate and initialize devices.
3. *The kernel loads.* Ntldr passes information collected by `Ntdetect.com` to `Ntoskrnl.exe`. Ntoskrnl then loads the kernel, Hardware Abstraction Layer (`Hal.dll`), and Registry information. An indicator near the bottom of the screen details progress.
4. *Drivers load and the user logs on.* Networking-related components (for example, TCP/IP) load simultaneously with other services and the `Begin Logon` prompt appears onscreen. After a user logs on successfully, Windows updates the Last Known Good Configuration information to reflect the current configuration state.
5. *Plug and Play detects and configures new devices.* If new devices are detected, they are assigned resources. Windows extracts the necessary driver files from `Driver.cab`. If the driver files are not found, the user is prompted to provide them. Device detection occurs simultaneously with the operating system logon process.

The following files are processed during Windows NT/2000/XP startup:

- `Ntldr`
- `Boot.ini`
- `Bootsect.dos` (multiple-boot systems only)
- `Ntbootdd.sys` (loaded only for SCSI drives)
- `Ntdetect.com`
- `Ntoskrnl.exe`
- `Hal.dll`
- Files in *`systemroot`*`\System32\Config` (Registry)
- Files in *`systemroot`*`\System32\Drivers` (drivers)

PC Maintenance Tools

To troubleshoot and repair PC systems properly, you need a few basic tools. If you intend to troubleshoot and repair PCs professionally, there are many more specialized tools you will want to purchase. These advanced tools enable you to more accurately diagnose problems and make jobs easier and faster. The basic tools that should be in every troubleshooter's toolbox are

- Simple hand tools for basic disassembly and reassembly procedures, including a flat blade and Phillips screwdrivers (both medium and small sizes), tweezers, an IC extraction tool, and a parts grabber or hemostat. Most of these items are included in $10–$20 starter toolkits found at most computer stores.
- Diagnostics software and hardware for testing components in a system.
- A multimeter that provides accurate measurements of voltage and resistance, as well as a continuity checker for testing cables and switches.
- Chemicals, such as contact cleaners; component freeze sprays; and compressed air for cleaning the system.
- Foam swabs, or lint-free cotton swabs if foam isn't available.
- Small nylon wire ties for "dressing" or organizing wires.

Some environments also might have the resources to purchase the following devices, although they're not required for most work:

- Memory-testing machines, used to evaluate the operation of single inline memory modules (SIMMs), dual inline memory modules (DIMMs), Rambus inline memory modules (RIMMs), or double data rate (DDR) DIMMs
- Serial and parallel loopback (or wrap) plugs to test serial and parallel ports
- A network cable scanner (if you work with networked PCs)
- A serial breakout box (if you use systems that operate over serial cables, such as Unix dumb terminals)

In addition, an experienced troubleshooter will probably want to have soldering and desoldering tools to fix bad serial cables. These tools are discussed in more detail in the following sections.

Hand Tools

When you work with PC systems, the tools required for nearly all service operations are simple and inexpensive. You can carry most of the required tools in a small pouch. Even a top-of-the-line "master mechanics" set fits inside a briefcase-sized container. The cost of these toolkits ranges from about $20 for a small service kit to $500 for one of the briefcase-sized deluxe kits. Compare these costs with what might be necessary for an automotive technician. An automotive service technician would have to spend $5,000–$10,000 or more for a complete set of tools. Not only are PC tools much less expensive, but I can tell you from experience that you don't get nearly as dirty working on computers as you do working on cars.

In this section, you learn about the tools required to assemble a kit that is capable of performing basic, board-level service on PC systems. One of the best ways to start such a set of tools is to purchase a small kit sold especially for servicing PCs.

Figure 23.1 shows some of the basic tools you can find in one of the small PC toolkits that sell for about $20.

Figure 23.1 The basic tools you need to work on your PC are shown here.

Note

Some tools aren't recommended because they are of limited use. However, they normally come with these types of kits.

You use nut drivers to remove the hexagonal-headed screws that secure the system-unit covers, adapter boards, disk drives, and power supplies in most systems. The nut drivers work much better than conventional screwdrivers.

Because some manufacturers have substituted slotted or Phillips-head screws for the more standard hexagonal-head screws, standard screwdrivers can be used for those systems.

Caution

When working in a cramped environment such as the inside of a computer case, screwdrivers with magnetic tips can be a real convenience, especially for retrieving that screw you dropped into the case. However, although I have used these types of screwdrivers many times with no problems, you should be aware of the damage a magnetic field can cause to magnetic storage devices such as floppy disks. Laying the screwdriver down on or near a floppy can damage the data on the disk. Fortunately, floppy disks aren't used that much anymore. Hard drives are shielded by a metal case; CD/DVD drives are not affected because they work optically; and memory and other chips are not affected by magnetic fields (unless they are magnitudes stronger than what you'll see in a hand tool).

Chip-extraction and insertion tools are rarely needed these days because memory chips are mounted on SIMMs, RIMMs, or DIMMs and processors use zero insertion force (ZIF) sockets or other user-friendly connectors. The ZIF socket has a lever that, when raised, releases the grip on the pins of the processor, enabling you to easily lift it out with your fingers.

However, if you work with older systems, you can use a chip extractor to install or remove memory chips (or other smaller chips) without bending any pins on the chip (see Figure 23.2). Usually, you pry out larger chips, such as microprocessors or ROMs, with the small screwdriver. Larger processors up through the 486 might require a chip extractor if they are mounted in the older low insertion force (LIF) socket. These chips have so many pins on them that a large amount of force is required to remove them, despite the fact that they call the socket "low insertion force." If you use a screwdriver on a large physical-size chip such as a 486, you risk cracking the case of the chip and permanently damaging it. The chip extractor tool for removing these chips has a very wide end with tines that fit between the pins on the chip to distribute the force evenly along the chip's underside. This minimizes the likelihood of breakage. Most of these types of extraction tools must be purchased specially for the chip you're trying to remove.

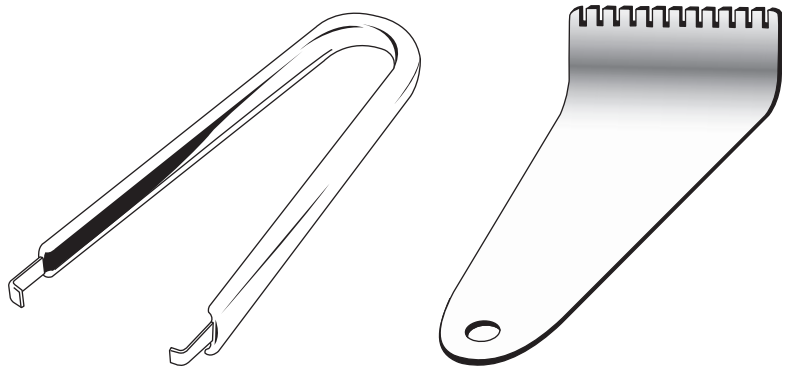

Figure 23.2 The chip extractor (left) is used to remove an individual RAM or ROM chip from a socket, but it would not be useful for a larger processor chip. Use an extractor such as the one on the right for extracting socketed processors—if the processor does not use a ZIF socket.

Tip

The older-style chip extractor shown on the left in Figure 23.2 does have another use as a keycap extractor. In fact, for this role it works quite well. By placing the tool over a keycap on a keyboard and squeezing the tool so the hooks grab under the keycap on opposite sides, you can cleanly and effectively remove the keycap from the keyboard without damage. This works much better than trying to pry the caps off with a screwdriver, which often results in damaging them or sending them flying across the room.

The tweezers and parts grabber can be used to hold any small screws or jumper blocks that are difficult to hold in your hand. The parts grabber is especially useful when you drop a small part into the interior of a system; usually, you can remove the part without completely disassembling the system (see Figure 23.3).

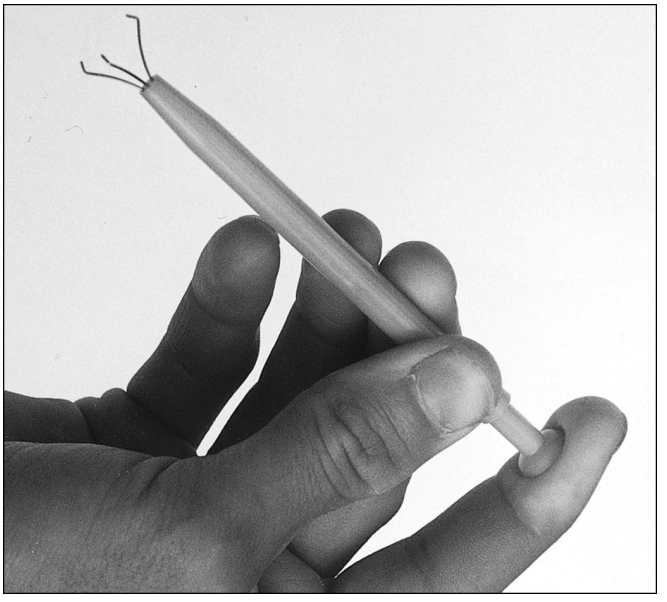

Figure 23.3 The parts grabber has three small metal prongs that can be extended to grab a part.

Finally, the Torx driver is a star-shaped driver that matches the special screws found in most Compaq systems and in many other systems as well (see Figure 23.4). You also can purchase tamperproof Torx drivers that can remove Torx screws with the tamper-resistant pin in the center of the screw. A tamperproof Torx driver has a hole drilled in it to allow clearance for the pin. Torx drivers come in a number of sizes, the most common being the T-10 and T-15.

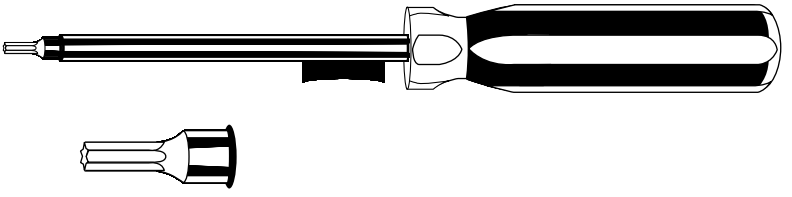

Figure 23.4 A Torx driver and bit.

Although this basic set is useful, you should supplement it with some other small hand tools, such as

- Needle-nose pliers
- Vise or clamp
- Hemostat
- File
- Wire cutter or wire stripper
- Small flashlight

Pliers are useful for straightening pins on chips, applying or removing jumpers, crimping cables, or grabbing small parts.

Hemostats are especially useful for grabbing small components, such as jumpers. They can also be helpful for smaller connectors, as well as for straightening bent pins or even retrieving small parts dropped in a system. I always have a set of both curved and straight hemostats in my toolkit.

The wire cutter or stripper, obviously, is useful for making or repairing cables or wiring. For example, you'd need these (along with a crimping tool) to make 10BASE-T Ethernet cables using UTP cable and RJ45 connectors (see Chapter 20, "Local Area Networking").

You can use a vise to install connectors on cables, crimp cables to the shape you want, and hold parts during delicate operations. In addition to the vise, Radio Shack sells a nifty "extra hands" device that has two movable arms with alligator clips on the end. This type of device is very useful for making cables or for other delicate operations during which an extra set of hands to hold something might be useful.

You can use the file to smooth rough metal edges on cases and chassis and to trim the faceplates on disk drives for a perfect fit.

You might often need a flashlight to illuminate system interiors, especially when the system is cramped and the room lighting is poor, or when you are working on a system underneath a user's desk. I consider this tool to be essential.

Another consideration for your toolkit is an electrostatic discharge (ESD) protection kit. This kit consists of a wrist strap with a ground wire and a specially conductive mat with its own ground wire. Using a kit like this when working on a system helps ensure that you never accidentally damage any of the components with a static discharge. You also can get just the wrist strap or the antistatic mat separately. A wrist strap is shown in Figure 23.5.

Note

It is possible (but not recommended) to work without an ESD protection kit if you're disciplined and careful about working on systems. If you don't have an ESD kit available, you can discharge yourself by touching some metallic part of the case. Be sure that any system you are working on is unplugged. Many systems today continue to feed power to the motherboard through the motherboard power connection whenever the computer is plugged in, even when the power switch is turned off. Working inside a PC that is still connected to a power source can be very dangerous.

The ESD kits, as well as all the other tools and much more, are available from a variety of tool vendors. Specialized Products Company and Jensen Tools are two of the most popular vendors of computer and electronic tools and service equipment. Their catalogs show an extensive selection of very high-quality tools. (These companies and several others are listed in the Vendor List on the DVD.) With a simple set of hand tools, you will be equipped for nearly every PC repair or installation situation. The total cost of these tools should be less than $150, which is not much considering the capabilities they provide.

A Word About Hardware

This section discusses some problems you might encounter with the hardware (screws, nuts, bolts, and so on) used in assembling a system.

Types of Hardware

One of the biggest aggravations you encounter in dealing with various systems is the different hardware types and designs that hold the units together.

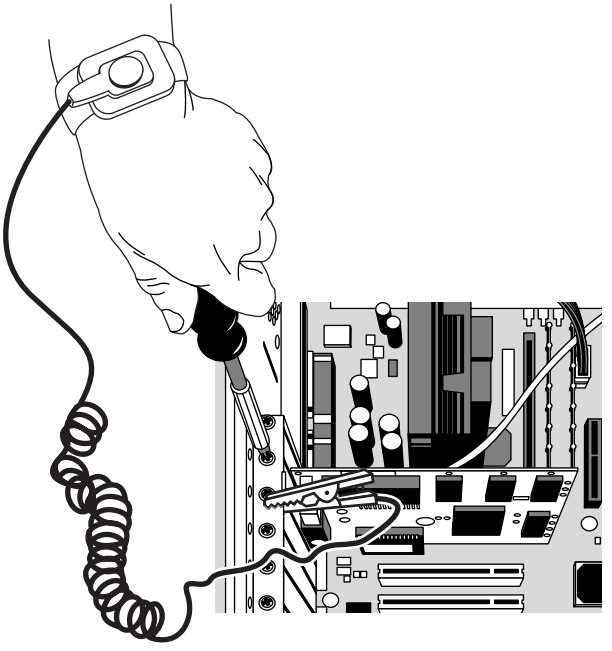

Figure 23.5 A typical ESD wrist strap clipped to a nonpainted surface in the case chassis.

For example, most systems use screws that fit 1/4-inch or 3/16-inch hexagonal nut drivers. IBM used these screws in all its original PC, XT, and AT systems, and most other system manufacturers use this standard hardware as well. Some manufacturers use different hardware, however. Compaq, for example, uses Torx screws extensively in many of its systems. A Torx screw has a star-shaped hole driven by the correct-size Torx driver. These drivers carry size designations such as T-8, T-9, T-10, T-15, T-20, T-25, T-30, and T-40.

A variation on the Torx screw is the tamperproof Torx screw found in power supplies, monitors, hard drives, and other assemblies. These screws are identical to the regular Torx screws, except that a pin sticks up from the middle of the star-shape hole in the screw. This pin prevents the standard Torx driver from entering the hole to grip the screw; a special tamperproof driver with a corresponding hole for the pin is required. An alternative is to use a small chisel to knock out the pin in the screw. Usually, a device sealed with these types of screws is considered to be a replaceable unit that rarely, if ever, needs to be opened.

Caution

Note that devices sealed with these types of screws generally have high voltages or other dangers waiting inside, so being able to bypass these screws doesn't mean it's always a good idea. Be sure you know what you are doing before disassembling devices such as monitors and power supplies.

Many manufacturers also use the more standard slotted-head and Phillips-head screws. Using tools on these screws is relatively easy, but tools do not grip these fasteners as well as hexagonal head or Torx screws do. In addition, the heads can be stripped more easily than the other types. Extremely cheap versions tend to lose bits of metal as they're turned with a driver, and the metal bits can fall onto the

motherboard. Stay away from cheap fasteners whenever possible; the headaches of dealing with stripped screws aren't worth it.

Some system manufacturers now use cases that snap together or use thumb screws. These are usually advertised as "no-tool" cases because you literally do not need any tools to remove the cover and access the major assemblies.

A company called Curtis sells special nylon plastic thumb screws that fit most normal cases and can be used to replace the existing screws to make opening the case a no-tool proposition. However, you still should always use metal screws to install internal components, such as adapter cards, disk drives, power supplies, and the motherboard, because the metal screws provide a ground point for these devices.

English Versus Metric

Another area of aggravation with hardware is the fact that two types of thread systems exist: English and metric. IBM used mostly English-threaded fasteners in its original line of systems, but many other manufacturers used metric-threaded fasteners.

The difference between the two becomes especially apparent with disk drives. American-manufactured drives typically use English fasteners, whereas drives made in Japan and Taiwan usually use metric. Whenever you replace a floppy drive in an older PC, you encounter this problem. Try to buy the correct screws and any other hardware, such as brackets, with the drive because they might be difficult to find as separate items. Many drive manufacturers offer retail drive kits that include all the required mounting components. The OEM's drive manual lists the correct data about a specific drive's hole locations and thread size.

Hard disks can use either English or metric fasteners; check your particular drive to see which type it uses. Most drives today use metric hardware.

Caution

Some screws in a system can be length-critical, especially screws used to retain hard disk drives. You can destroy some hard disks by using a mounting screw that's too long; the screw can puncture or dent the sealed disk chamber when you install the drive and fully tighten the screw. When you install a new drive in a system, always make a trial fit of the hardware to see how far the screws can be inserted into the drive before they interfere with its internal components. When in doubt, the drive manufacturer's OEM documentation will tell you precisely which screws are required and how long they should be.

Soldering and Desoldering Tools

In certain situations—such as repairing a broken wire, making cables, reattaching a component to a circuit board, removing and installing chips that are not in a socket, and adding jumper wires or pins to a board—you must use a soldering iron to make the repair.

Although virtually all repairs these days are done by simply replacing the entire failed board and many PC technicians never touch a soldering iron, you might find one useful in some situations. The most common case is when physical damage to a system has occurred, such as when someone rips the keyboard connector off a motherboard by pulling on the cable improperly. Simple soldering skills can save the motherboard in this case.

Most motherboards these days include I/O components, such as serial and parallel ports. Many of these ports are fuse-protected on the board; however, the fuse is usually a small soldered-in component. These fuses are designed to protect the motherboard circuits from being damaged by an external

source. If a short circuit or static charge from an external device blows these fuses, the motherboard can be saved if you can replace them.

To perform minor repairs such as these, you need a low-wattage soldering iron—usually about 25 watts. More than 30 watts generates too much heat and can damage the components on the board. Even with a low-wattage unit, you must limit the amount of heat to which you subject the board and its components. You can do this with quick and efficient use of the soldering iron and with the use of heatsinking devices clipped to the leads of the device being soldered. A *heatsink* is a small metal clip-on device designed to absorb excessive heat before it reaches the component the heatsink is protecting. In some cases, you can use a pair of hemostats as an effective heatsink when you solder a component.

To remove components soldered into place on a printed circuit board, you can use a soldering iron with a solder sucker. This device normally takes the form of a small tube with an air chamber and a plunger-and-spring arrangement. (I do not recommend the squeeze-bulb type of solder sucker.) The unit is "cocked" when you press the spring-loaded plunger into the air chamber. When you want to remove a device from a board, you use the soldering iron from the underside of the board and heat the point at which one of the component leads joins the circuit board until the solder melts. As soon as melting occurs, move the solder-sucker nozzle into position and press the actuator. When the plunger retracts, it creates a momentary suction that draws the liquid solder away from the connection and leaves the component lead dry in the hole.

Always perform the heating and suctioning from the underside of a board, not from the component side. Repeat this action for every component lead joined to the circuit board. When you master this technique, you can remove a small component in a minute or two with only a small likelihood of damage to the board or other components. Larger chips that have many pins can be more difficult to remove and resolder without damaging other components or the circuit board.

Tip

These procedures are intended for "through-hole" devices only. These are components whose pins extend all the way through holes in the board to the underside. Surface-mounted devices are removed with a completely different procedure, using much more expensive tools. Working on surface-mounted components is beyond the capabilities of all but the most well-equipped shops.

If you intend to add soldering and desoldering skills to your arsenal of abilities, you should practice. Take a useless circuit board and practice removing various components from the board; then, reinstall the components. Try to remove the components from the board by using the least amount of heat possible. Also, perform the solder-melting operations as quickly as possible, limiting the time the iron is applied to the joint. Before you install any components, clean out the holes through which the leads must project and mount the component in place. Then, apply the solder from the underside of the board, using as little heat and solder as possible.

Attempt to produce joints as clean as the joints the board manufacturer produced by machine. Soldered joints that do not look clean can keep the component from making a good connection with the rest of the circuit. This "cold-solder joint" is normally created because you have not used enough heat. Remember that you should not practice your new soldering skills on the motherboard of a system you are attempting to repair! Don't attempt to work on real boards until you are sure of your skills. I always keep a few junk boards around for soldering practice and experimentation.

Tip

When first learning to solder, you might be tempted to set the iron on the solder and leave it there until the solder melts. If the solder doesn't melt immediately when you apply the iron to it, you're not transferring the heat from the iron to the solder efficiently. This means that either the iron is dirty or there is debris between it and the solder. To clean the iron, take a wet sponge and drag it across the tip of the iron.

If after cleaning the iron, there's still some resistance, try to scratch the solder with the iron when it's hot. Generally, this removes any barriers to heat flow and instantly melts the solder.

No matter how good you get at soldering and desoldering, some jobs are best left to professionals. Components that are surface-mounted to a circuit board, for example, require special tools for soldering and desoldering, as do other components that have high pin densities.

Test Equipment

In some cases, you must use specialized devices to test a system board or component. This test equipment is not expensive or difficult to use, but it can add much to your troubleshooting abilities.

Electrical Testing Equipment

I consider a voltmeter to be required gear for proper system testing. A multimeter can serve many purposes, including checking for voltage signals at various points in a system, testing the output of the power supply, and checking for continuity in a circuit or cable. An outlet tester is an invaluable accessory that can check the electrical outlet for proper wiring. This capability is useful if you believe the problem lies outside the computer system.

Loopback Connectors (Wrap Plugs)

For diagnosing serial- and parallel-port problems, you need loopback connectors (also called wrap plugs), which are used to circulate, or wrap, signals (see Figure 23.6). The plugs enable the serial or parallel port to send data to itself for diagnostic purposes.

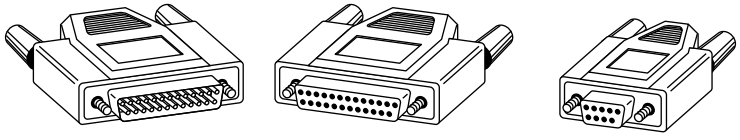

Figure 23.6 Typical wrap plugs, including 25-pin and 9-pin serial and 25-pin parallel versions.

Various types of loopback connectors are available. To accommodate all the ports you might encounter, you need one for the 25-pin serial port, one for the 9-pin serial port, and one for the 25-pin parallel port. Many companies, including IBM, sell the plugs separately, but be aware that you also need diagnostic software that can use them. Some diagnostic software products, such as Micro 2000's Micro-Scope, include loopback connectors with the product, or you can purchase them as an option for about $30 a set.

IBM sells a special combination plug that includes all three connector types in one compact unit. The device costs about the same as a normal set of wrap plugs. If you're handy, you can even make your own wrap plugs for testing. I include wiring diagrams for the three types of wrap plugs in Chapter 17,

"I/O Interfaces from Serial and Parallel to IEEE-1394 and USB." In that chapter, you also will find a detailed discussion of serial and parallel ports.

Besides simple loopback connectors, you also might want to have a breakout box for your toolkit. A breakout box is a DB25 connector device that enables you to make custom temporary cables or even to monitor signals on a cable. For most PC troubleshooting uses, a "mini" breakout box works well and is inexpensive.

Meters

Some troubleshooting procedures require that you measure voltage and resistance. You take these measurements by using a handheld Digital Multi-Meter (DMM). The meter can be an analog device (using an actual meter) or a digital-readout device. The DMM has a pair of wires called test leads or probes. The test leads make the connections so that you can take readings. Depending on the meter's setting, the probes measure electrical resistance, direct-current (DC) voltage, or alternating-current (AC) voltage.

Usually, each system-unit measurement setting has several ranges of operation. DC voltage, for example, usually can be read in several scales, to a maximum of 200 millivolts (mv), 2v, 20v, 200v, and 1,000v. Because computers use both +5v and +12v for various operations, you should use the 20v maximum scale for making your measurements. Making these measurements on the 200mv or 2v scale could "peg the meter" and possibly damage it because the voltage would be much higher than expected. Using the 200v or 1,000v scale works, but the readings at 5v and 12v are so small in proportion to the maximum that accuracy is low.

If you are taking a measurement and are unsure of the actual voltage, start at the highest scale and work your way down. Most of the better meters have autoranging capability—the meter automatically selects the best range for any measurement. This type of meter is much easier to operate. You simply set the meter to the type of reading you want, such as DC volts, and attach the probes to the signal source. The meter selects the correct voltage range and displays the value. Because of their design, these types of meters always have a digital display rather than a meter needle.

Caution

Whenever you are using a multimeter to test any voltage that could potentially be 110v or above, always use one hand to do the testing, not two. Either clip one lead to one of the sources and probe with the other or hold both leads in one hand.

If you hold a lead in each hand and accidentally slip, you can very easily become a circuit, allowing power to conduct or flow through you. When power flows from arm to arm, the path of the current is directly across the heart. Hearts tend to quit working when subjected to high voltages. They're funny that way.

I prefer the small digital meters; you can buy them for only slightly more than the analog style, and they're extremely accurate and much safer for digital circuits. Some of these meters are not much bigger than a cassette tape; they fit in a shirt pocket. Radio Shack sells a good unit (made for Radio Shack by Beckman) in the $25 price range; the meter is a half-inch thick, weighs 3 1/2 ounces, and is digital and autoranging, as well. This type of meter works well for most, if not all, PC troubleshooting and test uses.

Caution

You should be aware that many analog meters can be dangerous to digital circuits. These meters use a 9v battery to power the meter for resistance measurements. If you use this type of meter to measure resistance on some digital circuits, you can damage the electronics because you essentially are injecting 9v into the circuit. The digital meters universally run on 3v–5v or less.

Logic Probes and Logic Pulsers

A logic probe can be useful for diagnosing problems in digital circuits (see Figure 23.7). In a digital circuit, a signal is represented as either high (+5v) or low (0v). Because these signals are present for only a short time (measured in millionths of a second) or oscillate (switch on and off) rapidly, a simple voltmeter is useless. A logic probe is designed to display these signal conditions easily.

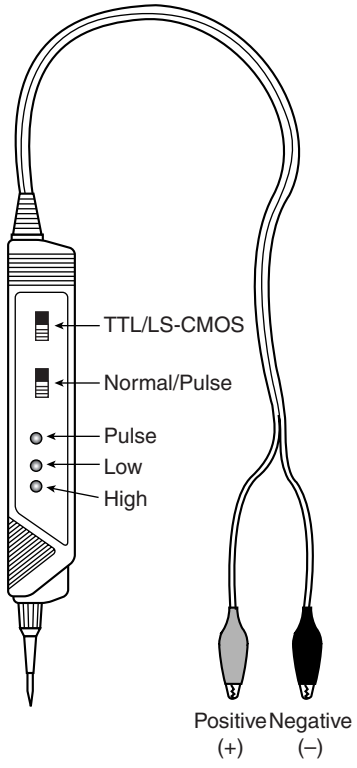

Figure 23.7 A typical logic probe.

Logic probes are especially useful for troubleshooting a dead system. By using the probe, you can determine whether the basic clock circuitry is operating and whether other signals necessary for system operation are present. In some cases, a probe can help you cross-check the signals at each pin on an integrated circuit chip. You can compare the signals present at each pin with the signals a known-good chip of the same type would show—a comparison that is helpful in isolating a failed component. Logic probes also can be useful for troubleshooting some disk drive problems by enabling you to test the signals present on the interface cable or drive-logic board.

A companion tool to the probe is the logic pulser. A *pulser* is designed to test circuit reaction by delivering a logical high (+5v) pulse into a circuit, usually lasting from 1 1/2 to 10 millionths of a second. Compare the reaction with that of a known-functional circuit. This type of device normally is used much less frequently than a logic probe, but in some cases it can be helpful for testing a circuit.

Outlet Testers

Outlet testers are very useful test tools. These simple, inexpensive devices, sold in hardware stores, test electrical outlets. You simply plug in the device, and three LEDs light up in various combinations, indicating whether the outlet is wired correctly.

Although you might think that badly wired outlets would be a rare problem, I have seen a large number of installations in which the outlets were wired incorrectly. Most of the time, the problem is in the ground wire. An improperly wired outlet can result in unstable system operation, such as random parity checks and lockups. With an improper ground circuit, currents can begin flowing on the electrical ground circuits in the system. Because the system uses the voltage on the ground circuits as a comparative signal to determine whether bits are 0 or 1, a floating ground can cause data errors in the system.

Caution

Even if you use a surge protector, it will not protect your system from an improperly wired outlet. Therefore, you still should use an outlet tester to ensure your outlet is computer friendly.

Once, while running one of my PC troubleshooting seminars, I used a system that I literally could not approach without locking it up. Whenever I walked past the system, the electrostatic field generated by my body interfered with the system and the PC locked up, displaying a parity-check error message. The problem was that the hotel at which I was giving the seminar was very old and had no grounded outlets in the room. The only way I could prevent the system from locking up was to run the class in my stocking feet because my leather-soled shoes were generating the static charge.

Other symptoms of bad ground wiring in electrical outlets are continual electrical shocks when you touch the case or chassis of the system. These shocks indicate that voltages are flowing where they should not be. This problem also can be caused by bad or improper grounds within the system. By using the simple outlet tester, you can quickly determine whether the outlet is at fault.

If you just walk up to a system and receive an initial shock, it's probably only static electricity. Touch the chassis again without moving your feet. If you receive another shock, something is very wrong. In this case, the ground wire actually has voltage applied to it. You should have a professional electrician check the outlet immediately.

If you don't like being a human rat in an electrical experiment, you can test the outlets with your multimeter. First, remember to hold both leads in one hand. Test from one blade hole to another. This should read between 110v and 125v, depending on the electrical service in the area. Then, check from each blade to the ground (the round hole). One blade hole, the smaller one, should show a voltage almost identical to the one you got from the blade-hole–to–blade-hole test. The larger blade hole when measured to ground should show less than 0.5v.

Because ground and neutral are supposed to be tied together at the electrical panel, a large difference in these readings indicates that they are not tied together. However, small differences can be accounted for by current from other outlets down the line flowing on the neutral, when there isn't any on the ground.

If you don't get the results you expect, call an electrician to test the outlets for you. More weird computer problems are caused by improper grounding and other power problems than people like to believe.

Memory Testers

I now consider a memory test machine an all-but-mandatory piece of equipment for anyone serious about performing PC troubleshooting and repair as a profession. The tester is a small device designed to evaluate SIMMs, DIMMs, RIMMs, and other types of memory modules, including individual chips such as those used as cache memory. These testers can be somewhat expensive, costing upward of $1,000–$2,500 or more, but these machines are the only truly accurate way to test memory.

Without one of these testers, you are reduced to testing memory by running a diagnostic program on the PC and testing the memory as it is installed. This can be very problematic because the memory diagnostic program can do only two things to the memory: write and read. A SIMM/DIMM/RIMM tester can do many things a memory diagnostic running in a PC can't do, such as

- Identify the type of memory
- Identify the memory speed
- Identify whether the memory has parity or is using bogus parity emulation
- Vary the refresh timing and access speed timing
- Locate single bit failures
- Detect power- and noise-related failures
- Detect solder opens and shorts
- Isolate timing-related failures
- Detect data retention errors

No conventional memory diagnostic software can do these things because it must rely on the fixed access parameters set up by the memory controller hardware in the motherboard chipset. This prevents the software from being capable of altering the timing and methods used to access the memory. You might have memory that fails in one system and works in another when the chips are actually bad. This type of intermittent problem is almost impossible to detect with diagnostic software.

The bottom line is that there is no way you can test memory with true accuracy while it is installed in a PC; a memory tester is required for comprehensive and accurate testing. The price of a memory tester can be justified very easily in a shop environment where a lot of PCs are tested because many software and hardware upgrades today require the addition of new memory. With the large increases in the amount of memory in today's systems and the stricter timing requirements of newer motherboard designs, it has become even more important to be able to identify or rule out memory as a cause of system failure. One company manufacturing memory testers I recommend is Tanisys Technologies; its Darkhorse Systems line of memory testers can handle virtually every type of memory on the market. See the Vendor List on the DVD for more information. Also, see Chapter 6, "Memory," for more information on memory in general.

Special Tools for the Enthusiast

All the tools described so far are commonly used by most technicians. However, a few additional tools do exist that a true PC enthusiast might want to have.

Electric Screwdriver

Perhaps the most useful tool I use is an electric screwdriver. It enables me to disassemble and reassemble a PC in record time and makes the job not only faster but easier as well. I like the type with a clutch you can use to set how tight it will make the screws before slipping; such a clutch makes it even faster to use. If you use the driver frequently, it makes sense to use the type with replaceable, rechargeable batteries, so when one battery dies you can quickly replace it with a fresh one.

Caution

Note that using an electric screwdriver when installing a motherboard can be dangerous because the bit can easily slip off the screw and damage the board. A telltale series of swirling scratches near the screw holes on the board can be the result, for which most manufacturers rightfully deny a warranty claim. Be especially careful if your motherboard is retained with Phillips-head screws because they are extremely easy for the bit to slip out of. Normally, I recommend using only Torx-head or hex-head screws to retain the motherboard because they are far more resistant to having the bit slip out and cause damage.

With the electric screwdriver, I recommend getting a complete set of English and metric nut driver tips as well as various sizes of Torx, flat-head, and Phillips-head screwdriver tips.

Tamperproof Torx Bits

Any devices such as power supplies and monitors are held together with tamperproof Torx screws. Tamperproof Torx driver sets are available from any good electronics tool supplier.

Temperature Probe

Determining the interior temperature of a PC is often useful when diagnosing whether heat-related issues are causing problems. This requires some way of measuring the temperature inside the PC, as well as the ambient temperature outside the system. The simplest and best tool I've found for the job is the digital thermometers sold at most auto parts stores for automobile use. They are designed to read the temperature inside and outside the car and normally come with an internal sensor, as well as one at the end of a length of wire.

With this type of probe, you can run the wired sensor inside the case (if it is metal, make sure it does not directly touch the motherboard or other exposed circuits where it might cause a short) with the wires slipped through a crack in the case or out one of the drive bays. Then, with the system running you can take the internal temperature as well as read the room's ambient temperature. Normally, the maximum limit for internal temperature should be 110°F (43°C) or less. If your system is running near or above that temperature, problems can be expected. You also can position the probe in the system to be near any heat producing devices, such as the processor, video card, and so on, to see the effect of the device. Probing the temperature with a device such as this enables you to determine whether additional cooling is necessary (that is, adding more cooling fans to the case) and enables you to check to see whether the added fans are helping.

Infrared Thermometer

Another useful temperature tool is a noncontact infrared (IR) thermometer, which is a special type of sensor that can measure the temperature of an object without physically touching it (see Figure 23.8). You can take the temperature reading of an object in seconds by merely pointing the handheld device at the object you want to measure and pulling a trigger.

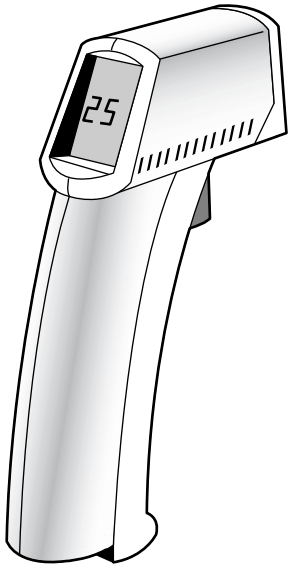

Figure 23.8 A noncontact infrared thermometer.

An IR thermometer works by capturing the infrared energy naturally emitted from all objects warmer than absolute zero (0° Kelvin). Infrared energy is a part of the electromagnetic spectrum with a frequency below that of visible light, which means it is invisible to the human eye. Infrared wavelengths are between 0.7 microns and 1000 microns (millionths of a meter), although infrared thermometers typically measure radiation in the range 0.7–14 microns.

Because IR thermometers can measure the temperature of objects without touching them, they are ideal for measuring chip temperatures in a running system—especially the temperature of the CPU heatsink. By merely pointing the device at the top of the CPU and pulling the trigger, you can get a very accurate measurement in about 1 second. To enable more accuracy in positioning, many IR thermometers incorporate a laser pointer, which is used to aim the device.

IR thermometers are designed to measure IR radiation from a device; they can't be used to measure air temperature. The sensors are specifically designed so that the air between the sensor and target does not affect the temperature measurement.

Although several IR thermometers are available on the market, I use and recommend the Raytek (`www.raytek.com`) MiniTemp series, which consists of the MT2 and MT4. Both units are identical, but the MT4 includes a laser pointer for aiming. The MT2 and MT4 are capable of measuring temperatures between 0° and 500°F (-18°–260°C) in one half of a second with an accuracy of about plus or minus 3°F (2°C). They cost $80–$100 and are available from NAPA auto parts stores (these devices have many uses in automotive testing as well) and other tool outlets.

Large Claw-Type Parts Grabber

One of the more useful tools in my toolbox is a large claw-type parts grabber, normally sold in stores that carry automotive tools. Having one of these around has saved many hours of frustration digging back into a system or behind a desk for a loose or dropped screw.

These grabbers are very similar to the small claw-type grabber included with most PC toolkits, except they are much larger—normally two feet or so in length. They can be useful if you drop a screw down inside a tower case, or even on the floor under or behind a desk or cabinet. Although magnetic parts grabbers are also available, I normally recommend the claw-type because using a powerful magnet near a computer can cause problems with any disk storage media you have about, or even the hard disk or CRT-type display.

Preventive Maintenance

Preventive maintenance is the key to obtaining years of trouble-free service from your computer system. A properly administered preventive maintenance program pays for itself by reducing problem behavior, data loss, and component failure and by ensuring a long life for your system. In several cases, I have "repaired" an ailing system with nothing more than a preventive maintenance session. Preventive maintenance also can increase your system's resale value because it will look and run better.

Developing a preventive maintenance program is important to everyone who uses or manages personal computer systems. The two types of preventive maintenance procedures are active and passive.

An *active* preventive maintenance program includes procedures that promote a longer, trouble-free life for your PC. This type of preventive maintenance primarily involves the periodic cleaning of the system and its components. The following sections describe several active preventive maintenance procedures, including cleaning and lubricating all major components, reseating chips and connectors, and reformatting hard disks.

Passive preventive maintenance includes steps you can take to protect a system from the environment, such as using power-protection devices; ensuring a clean, temperature-controlled environment; and preventing excessive vibration. In other words, passive preventive maintenance means treating your system well.

Active Preventive Maintenance Procedures

How often you should perform active preventive maintenance procedures depends on the system's environment and the quality of the system's components. If your system is in a dirty environment, such as a machine shop floor or a gas station service area, you might need to clean your system every three months or less. For normal office environments, cleaning a system every few months to a year is usually fine. However, if you open your system after one year and find dust bunnies inside, you should probably shorten the cleaning interval.

Other hard disk preventive maintenance procedures include making periodic backups of your data and critical areas, such as boot sectors, file allocation tables (FATs), and directory structures on the disk. Also, you should defragment hard disks at least once a month to maintain disk efficiency and speed.

The following is a sample weekly disk maintenance checklist:

- Back up any data or important files.
- Delete all temporary files, such as
  - `*.tmp` (files with a `.tmp` extension)
  - `~*.*` (files beginning with a tilde (~))
  - `*.chk` (files with a `.chk` extension)
  - Web browser history and temporary Internet files

- Empty the Recycle Bin.
- Finally, run the defragmenting program.

The following are some monthly maintenance procedures you should perform:

- Create an operating system startup disk.
- Check for and install any updated drivers for video cards, sound cards, modems, and other devices.
- Check for and install any operating system updates.
- Check for and install antivirus software updates.
- Clean the system, including the monitor screen, keyboard, CD/DVD drives, floppy drive, mouse, and so on.
- Check that all system fans are operating properly, including the CPU heatsink, power supply, and any chassis fans.

System Backups

One of the most important preventive maintenance procedures is the performance of regular system backups. A sad reality in the computer repair and servicing world is that hardware can always be repaired or replaced, but data cannot. Many hard disk troubleshooting and service procedures, for example, require that you repartition or reformat the disk, which overwrites all existing data.

The hard disk drive capacity in a typical PC has grown far beyond the point at which floppy disks are a viable backup solution. Backup solutions that employ floppy disk drives, such as DOS backup software, are insufficient and too costly for hard disk backups in today's systems. It would take 2,867 1.44MB floppy disks, for example, to back up the 4GB hard disk in my portable system! That would cost more than $1,000 in disks, not to mention the time involved.

The best form of backup has traditionally been magnetic tape. The two main standards are Travan and DAT (digital audio tape). Travan drives are generally slower and hold less than DAT drives, but both are available in relatively competitive versions. The latest Travan NS (Network series) tape drives store 10GB/20GB (raw/compressed) on a single tape, whereas DAT DDS3 (digital data storage) drives store 12GB/24GB per tape, and newer DAT DDS4 drives store 20GB/40GB per tape. These tapes typically cost less than $30.

Tape is generally the fastest and safest form of backup, especially considering you can make multiple backups to different tapes, and even move some of the backups offsite in case of theft or fire. Still, the initial cost of the drive has been an impediment to many. The increasing popularity of writable CD-RW drives presents an alternative, although backing up an entire drive requires multiple CDs.

Although a tape drive can cost up to $500 or more, the media costs are really far more significant than the cost of the drive. If you perform responsible backups, you should have at least three sets of media for each system you are backing up. You should use each media set on a rotating basis, and store one of them offsite at all times, in case of fire or theft. You also should introduce new media to the rotation after approximately a year to prevent excessive wear. If you are backing up multiple systems, these media costs can add up quickly.

In addition, you should factor in the cost of your time. If a backup requires manual intervention to change the media during the job, I don't recommend it. A backup system should be capable of fitting a complete backup on a single tape so you can schedule the job to run unattended. If someone has to hang around to switch tapes every so often, backups become a real chore and are more likely to be overlooked. Also, every time a media change occurs, the likelihood of errors and problems you might

not see until you attempt to perform a restore operation substantially increases. Backups are far more important than most people realize, and spending a little more on a quality piece of hardware such as a Travan or DAT drive will pay off in the long run with greater reliability, lower media costs, higher performance, and unattended backups that contain the entire system file structure.

With the increasing popularity of removable bulk storage media such as cartridge drives, including Iomega's Zip and Jaz drives, and rewritable CDs (CD-RWs), many people are using these devices to perform system backups. In most cases, however, although these drives are excellent for storing backup copies of selected data, they are impractical solutions for regular system backups. This can be due to both the capacity of the media in relation to today's hard disk drives and the cost of the media.

Although the media for a CD-RW drive are quite inexpensive, it would take several discs to back up a multigigabyte hard drive, adding a measure of inconvenience to the backup process that makes it far less likely to be performed on a regular basis. Even the Iomega Jaz drive that can store up to 2GB on a single cartridge can require several media changes to complete a single system backup. Add this to the fact that the Jaz cartridges can cost $125 or more each, and you have a backup solution that is both inconvenient and expensive.

Another alternative for backup is to install a second hard drive of equal (or larger) capacity and simply copy from one drive to another. With the low cost of drives these days, this is an economical, fast, and efficient method; however, if a disaster occurs, such as theft or fire, you'll still lose everything. Also, with only one backup, if your backup goes bad when you depend on it, you'll be without any other alternatives.

What I like to do is use a second hard disk to make complete backups of my entire drive weekly, followed by monthly backups to tape. This enables me to not only back up quickly and efficiently, but I also can easily swap my backup slave drive for a failed master and be up and running again in minutes. The tape backup then becomes more of an insurance policy.

Tip

No matter which backup solution you use, the entire exercise is pointless if you cannot restore your data from the storage medium. You should test your backup system by performing random file restores at regular intervals to ensure the viability of your data.

Cleaning a System

One of the most important operations in a good preventive maintenance program is regular and thorough cleaning of the system. Dust buildup on the internal components can lead to several problems. One is that the dust acts as a thermal insulator, which prevents proper system cooling. Excessive heat shortens the life of system components and adds to the thermal stress problem caused by greater temperature changes between the system's power-on and power-off states. Additionally, the dust can contain conductive elements that can cause partial short circuits in a system. Other elements in dust and dirt can accelerate corrosion of electrical contacts, resulting in improper connections. In all, the regular removal of any layer of dust and debris from within a computer system benefits that system in the long run.

Tip

Cigarette smoke contains chemicals that can conduct electricity and cause corrosion of computer parts. The smoke residue can infiltrate the entire system, causing corrosion and contamination of electrical contacts and sensitive components, such as floppy drive read/write heads and optical drive lens assemblies. You should avoid smoking near computer equipment and encourage your company to develop and enforce a similar policy.

Floppy disk drives are particularly vulnerable to the effects of dirt and dust. A floppy drive is essentially a large "hole" in the system case through which air continuously flows. Therefore, these drives accumulate a large amount of dust and chemical buildup within a short time. Hard disk drives, on the other hand, do not present quite the same problem. Because the head disk assembly (HDA) in a hard disk is a sealed unit with a single barometric vent, no dust or dirt can enter without passing through the barometric vent filter. This filter ensures that contaminating dust and particles cannot enter the interior of the HDA. Thus, cleaning a hard disk requires blowing off the dust and dirt from outside the drive. No internal cleaning is required.

Disassembly and Cleaning Tools

Properly cleaning the system and all the boards inside requires certain supplies and tools. In addition to the tools required to disassemble the unit, you should have these items:

- Contact cleaning solution
- Canned air
- A small brush
- Lint-free foam cleaning swabs
- Antistatic wrist-grounding strap

You also might want to acquire these optional items:

- Foam tape
- Low-volatile room-temperature vulcanizing (RTV) sealer
- Silicone-type lubricant
- Computer vacuum cleaner

These simple cleaning tools and chemical solutions enable you to perform most common preventive maintenance tasks.

Chemicals

Chemicals can be used to help clean, troubleshoot, and even repair a system. You can use several types of cleaning solutions with computers and electronic assemblies. Most fall into the following categories:

- Standard cleaners
- Contact cleaner/lubricants
- Dusters

Tip

The makeup of many of the chemicals used for cleaning electronic components has been changing because many of the chemicals originally used are now considered environmentally unsafe. They have been attributed to damaging the earth's ozone layer. Chlorine atoms from chlorofluorocarbons (CFCs) and chlorinated solvents attach themselves to ozone molecules and destroy them. Many of these chemicals are now strictly regulated by federal and international agencies in an effort to preserve the ozone layer. Most of the companies that produce chemicals used for system cleaning and maintenance have had to introduce environmentally safe replacements. The only drawback is that many of these safer chemicals cost more and usually do not work as well as those they've replaced.

Standard Cleaners

For the most basic function—cleaning components, electrical connectors, and contacts—one of the most useful chemicals is 1,1,1 trichloroethane. This substance is an effective cleaner that was at one time used to clean electrical contacts and components because it does not damage most plastics and board materials. In fact, trichloroethane is very useful for cleaning stains on the system case and keyboard as well. Unfortunately, trichloroethane is now being regulated as a chlorinated solvent, along with CFCs (chlorofluorocarbons) such as Freon, but electronic chemical-supply companies are offering several replacements.

Alternative cleaning solutions are available in a variety of types and configurations. You can use pure isopropyl alcohol, acetone, Freon, trichloroethane, or a variety of other chemicals. Most board manufacturers and service shops are now leaning toward alcohol, acetone, or other chemicals that do not cause ozone depletion and comply with government regulations and environmental safety.

Recently, new biodegradable cleaners described as "citrus-based cleaners" have become popular in the industry, and in many cases are more effective and more economical for circuit board and contact cleaning. These cleaners are commonly known as d-limonene or citrus terpenes and are derived from orange peels, which gives them a strong (but pleasant) citric odor. Another type of terpene is called a-pinene, and is derived from pine trees. You must exercise care when using these cleaners, however, because they can cause swelling of some plastics, especially silicone rubber and PVC.

You should make sure your cleaning solution is designed to clean computers or electronic assemblies. In most cases, this means that the solution should be chemically pure and free from contaminants or other unwanted substances. You should not, for example, use drugstore rubbing alcohol for cleaning electronic parts or contacts because it is not pure and could contain water or perfumes. The material must be moisture-free and residue-free. The solutions should be in liquid form, not a spray. Sprays can be wasteful, and you almost never spray the solution directly on components. Instead, wet a foam or chamois swab used for wiping the component. These electronic-component cleaning solutions are available at any good electronics parts store.

Contact Cleaner/Lubricants

These chemicals are similar to the standard cleaners but include a lubricating component. The lubricant eases the force required when plugging and unplugging cables and connectors, reducing strain on the devices. The lubricant coating also acts as a conductive protectant that insulates the contacts from corrosion. These chemicals can greatly prolong the life of a system by preventing intermittent contacts in the future.

A unique type of contact enhancer and lubricant called Stabilant 22 is currently on the market. This chemical, which you apply to electrical contacts, greatly enhances the connection and lubricates the contact point; it is much more effective than conventional contact cleaners or lubricants.

Stabilant 22 is a liquid-polymer semiconductor; it behaves like liquid metal and conducts electricity in the presence of an electric current. The substance also fills the air gaps between the mating surfaces of two items that are in contact, making the surface area of the contact larger and also keeping out oxygen and other contaminants that can corrode the contact point.

This chemical is available in several forms. Stabilant 22 is the concentrated version, whereas Stabilant 22a is a version diluted with isopropanol in a 4:1 ratio. An even more diluted 8:1-ratio version is sold in many high-end stereo and audio shops under the name Tweek. Just 15ml of Stabilant 22a sells for about $40; a liter of the concentrate costs about $4,000!

As you can plainly see, Stabilant 22 is fairly expensive, but little is required in an application, and nothing else has been found to be as effective in preserving electrical contacts. (NASA uses the

chemical on spacecraft electronics.) An application of Stabilant can provide protection for up to 16 years, according to its manufacturer, D.W. Electrochemicals. You will find the company's address and phone number in the Vendor List on the DVD.

Stabilant is especially effective on I/O slot connectors, adapter-card edge and pin connectors, disk drive connectors, power-supply connectors, and virtually any connector in the PC. In addition to enhancing the contact and preventing corrosion, an application of Stabilant lubricates the contacts, making insertion and removal of the connector easier.

Dusters

Compressed gas often is used as an aid in system cleaning. You use the compressed gas as a blower to remove dust and debris from a system or component. Originally, these dusters used CFCs (chlorofluorocarbons) such as Freon, whereas modern dusters use either HFCs (hydrofluorocarbons such as difluoroethane) or carbon dioxide, neither of which is known to damage the ozone layer. Be careful when you use these devices because some of them can generate a static charge when the compressed gas leaves the nozzle of the can. Be sure you are using the type approved for cleaning or dusting off computer equipment, and consider wearing a static grounding strap as a precaution. The type of compressed-air cans used for cleaning camera equipment can sometimes differ from the type used for cleaning static-sensitive computer components.

When using these compressed air products, be sure you hold the can upright so that only gas is ejected from the nozzle. If you tip the can, the raw propellant will come out as a cold liquid, which not only is wasteful but can damage or discolor plastics. You should use compressed gas only on equipment that is powered off, to minimize any chance of damage through short circuits.

Closely related to compressed-air products are chemical-freeze sprays. These sprays are used to quickly cool down a suspected failing component, which often temporarily restores it to normal operation. These substances are not used to repair a device, but to confirm that you have found a failed device. Often, a component's failure is heat-related, and cooling it temporarily restores it to normal operation. If the circuit begins operating normally, the device you are cooling is the suspect device.

Vacuum Cleaners

Some people prefer to use a vacuum cleaner instead of canned gas dusters for cleaning a system. Canned gas is usually better for cleaning in small areas. A vacuum cleaner is more useful when you are cleaning a system loaded with dust and dirt. You can use the vacuum cleaner to suck out the dust and debris instead of simply blowing it around on the other components, which sometimes happens with canned air. For onsite servicing (when you are going to the location of the equipment instead of the equipment coming to you), canned air is easier to carry in a toolkit than a small vacuum cleaner. Tiny vacuum cleaners also are available for system cleaning. These small units are easy to carry and can serve as an alternative to compressed air cans.

Some special vacuum cleaners are specifically designed for use on and around electronic components; they are designed to minimize electrostatic discharge (ESD) while in use. If you are using a regular vacuum cleaner and not one specifically designed with ESD protection, you should take precautions, such as wearing a grounding wrist strap. Also, if the cleaner has a metal nozzle, be careful not to touch it to the circuit boards or components you are cleaning.

Brushes and Swabs

You can use a small makeup, photographic, or paint brush to carefully loosen the accumulated dirt and dust inside a PC before spraying it with canned air or using the vacuum cleaner. Be careful about generating static electricity, however. In most cases, you should not use a brush directly on circuit boards, but only on the case interior and other parts, such as fan blades, air vents, and keyboards.

Wear a grounded wrist strap if you are brushing on or near any circuit boards, and brush slowly and lightly to prevent static discharges from occurring.

Use cleaning swabs to wipe off electrical contacts and connectors, disk drive heads, and other sensitive areas. The swabs should be made of foam or synthetic chamois material that does not leave lint or dust residue. Unfortunately, proper foam or chamois cleaning swabs are more expensive than typical cotton swabs. Do not use cotton swabs because they leave cotton fibers on everything they touch. Cotton fibers are conductive in some situations and can remain on drive heads, which can scratch disks. Foam or chamois swabs can be purchased at most electronics supply stores.

Caution

One item to avoid is an eraser for cleaning contacts. Many people (including me) have recommended using a soft pencil-type eraser for cleaning circuit-board contacts. Testing has proven this to be bad advice for several reasons. One reason is that any such abrasive wiping on electrical contacts generates friction and an ESD. This ESD can be damaging to boards and components, especially the newer low-voltage devices. These devices are especially static sensitive, and cleaning the contacts without a proper liquid solution is not recommended. Also, the eraser will wear off the gold coating on many contacts, exposing the tin contact underneath, which rapidly corrodes when exposed to air.

Some companies sell pre-moistened contact cleaning pads soaked in a proper contact cleaner and lubricant. These pads are safe to wipe on conductors and contacts with no likelihood of ESD damage or abrasion of the gold plating.

Silicone Lubricants

You can use a silicone lubricant such as WD-40 to lubricate the door mechanisms on floppy disk drives and any other part of the system that might require clean, non-oily lubrication. Other items you can lubricate are the disk-drive–head slider rails and even printer-head slider rails, to provide smoother operation.

Using silicone instead of conventional oils is important because silicone does not gum up and collect dust and other debris. Always use the silicone sparingly. Do not spray it anywhere near the equipment because it tends to migrate and will end up where it doesn't belong (such as on drive heads). Instead, apply a small amount to a toothpick or foam swab and dab the silicone lubricant on the components where needed. You can use a lint-free cleaning stick soaked in silicone to lubricate the metal print-head rails in a printer.

Obtaining Required Tools and Accessories

You can obtain most of the cleaning chemicals and tools discussed in this chapter from an electronics supply house, or even your local Radio Shack. A company called Chemtronics specializes in chemicals for the computer and electronics industry. These and other companies that supply tools, chemicals, and other computer and electronic cleaning supplies are listed in the Vendor List on the DVD. With all these items on hand, you should be equipped for most preventive maintenance operations.

Disassembling and Cleaning Procedures

To properly clean your system, you must at least partially disassemble it. Some people go as far as to remove the motherboard. Removing the motherboard results in the best possible access to other areas of the system; but in the interest of saving time, you probably need to disassemble the system only to the point at which the motherboard is completely visible.

To do this, remove all the system's plug-in adapter cards and the disk drives. Complete system disassembly and reassembly procedures are listed in Chapter 22, "Building or Upgrading Systems."

Although you can clean the heads of a floppy drive with a cleaning disk without opening the system unit's cover, you probably will want to do more thorough cleaning. In addition to the drive heads, you should clean and lubricate the door mechanism and clean any logic boards and connectors on the drive. This procedure usually requires removing the drive.

Next, do the same thing with the hard disk drives: Clean the logic boards and connectors, and lubricate the grounding strap. To do this, you must remove the hard disk assembly. As a precaution, be sure your data is backed up first.

Reseating Socketed Chips

Another primary preventive maintenance function is to undo the effects of chip creep. As your system heats and cools, it expands and contracts, and the physical expansion and contraction can cause components that are plugged in to sockets to gradually work their way out of those sockets. This process is called *chip creep*. To correct its effects, you must find all socketed components in the system and ensure that they are properly reseated.

In most of today's systems, the memory chips are installed in socketed SIMMs, RIMMs, or DIMMs. SIMM/RIMM/DIMM devices are retained securely in their sockets by a positive latching mechanism and cannot creep out. The memory single inline pin package (SIPP) devices (SIMMs with pins rather than contacts) used in older systems are not retained by a latching mechanism, however, and therefore can creep out of their sockets. Standard socketed memory chips are prime candidates for chip creep; most other logic components are soldered in. On an older system, you also might find the ROM chips, a math coprocessor, and even the main system processor in sockets. Newer systems place the CPU in a ZIF socket, which has a lever that releases the grip of the socket on the chip. In most cases, very little creep occurs with a ZIF socket. However, sometimes a connection oxidizes and simply removing and re-inserting the processor wipes the contact clean and restores normal operation. In most current systems, the memory (in SIMMs, RIMMs, or DIMMs) and the processor are the only components you find in sockets; all others are soldered in.

Exceptions, however, can exist. A socketed component in one system might not be socketed in another—even if both are from the same manufacturer. Sometimes this difference results from a parts-availability problem when the boards are manufactured. Rather than halt the assembly line when a part is not available, the manufacturer adds a socket instead of the component. When the component becomes available, it is plugged in and the board is finished.

To ensure that all components are fully seated in their sockets, place your hand on the underside of the board and then apply downward pressure with the thumb of your other hand (from the top) on the chip to be seated. For larger chips, seat the chip carefully in the socket, and press separately on each end of the chip with your thumb to make sure the chip is fully seated. (The processor and math coprocessor chips can usually be seated in this manner.) In most cases, you should hear a crunching sound as the chip makes its way back into the socket. Because of the great force that is sometimes required to reseat the chips, this operation is difficult if you do not remove the board.

For motherboards, forcibly seating chips can be dangerous if you do not directly support the board from the underside with your hand. Too much pressure on the board can cause it to bow or bend in the chassis, and the pressure can crack it before the chip is fully seated. The plastic standoffs that hold the board up off the metal chassis are spaced too far apart to properly support the board under this kind of stress. Try this operation only if you can remove and support the board adequately from underneath.

You might be surprised to know that, even if you fully seat a chip, it might need reseating again within a year. The creep usually is noticeable within a year or less.

Cleaning Boards

After reseating any socketed devices that might have crept out of their sockets, the next step is to clean the boards and all connectors in the system. For this step, use the cleaning solutions and the lint-free swabs mentioned earlier.

First, clean the dust and debris off the board and then clean any connectors on the board. To clean the boards, using a vacuum cleaner designed for electronic assemblies and circuit boards or a duster can of compressed gas is usually best. The dusters are especially effective at blasting any dust and dirt off the boards.

Also, blow any dust out of the power supply, especially around the fan intake and exhaust areas. You do not need to disassemble the power supply to do this; simply use a duster can and blast the compressed air into the supply through the fan exhaust port. This will blow the dust out of the supply and clean off the fan blades and grill, which will help with system airflow.

Caution

Be careful with ESD, which can cause damage when you are cleaning electronic components. Take extra precautions in the dead of winter or in extremely dry, high-static environments. You can apply antistatic sprays and treatments to the work area to reduce the likelihood of ESD damage.

An antistatic wrist-grounding strap is recommended (refer to Figure 23.5, earlier in this chapter). This should be connected to a ground on the card or board you are wiping. This strap ensures that no electrical discharge occurs between you and the board. An alternative method is to keep a finger or thumb on the ground of the motherboard or card as you wipe it off.

Cleaning Connectors and Contacts

Cleaning the connectors and contacts in a system promotes reliable connections between devices. On a motherboard, you should clean the slot connectors, power supply connectors, keyboard and mouse connectors, and speaker connector. For most plug-in cards, you should clean the edge connectors that plug in to slots on the motherboard and any other connectors, such as external ones mounted on the card bracket.

Submerge the lint-free swabs in the liquid cleaning solution. If you are using the spray, hold the swab away from the system and spray a small amount on the foam end until the solution starts to drip. Then, use the soaked foam swab to wipe the connectors on the boards. Presoaked wipes are the easiest to use—simply wipe them along the contacts to remove any accumulated dirt and leave a protective coating behind.

On the motherboard, pay special attention to the slot connectors. Be liberal with the liquid; resoak the foam swab repeatedly, and vigorously clean the connectors. Don't worry if some of the liquid drips on the surface of the motherboard. These solutions are entirely safe for the whole board and will not damage the components.

Use the solution to wash the dirt off the gold contacts in the slot connectors, and then clean any other connectors on the board. Clean the keyboard and mouse connectors, the grounding positions where screws ground the board to the system chassis, the power-supply connectors, the speaker connectors, and the battery connectors.

If you are cleaning a plug-in board, pay special attention to the edge connector that mates with the slot connector on the motherboard. When people handle plug-in cards, they often touch the gold contacts on these connectors. Touching the gold contacts coats them with oils and debris, which

prevents proper contact with the slot connector when the board is installed. Make sure these gold contacts are free of all finger oils and residue. It is a good idea to use one of the contact cleaners that has a conductive lubricant, which makes it easier to push the adapter into the slot and also protects the contacts from corrosion.

You also should use the swab and solution to clean the ends of ribbon cables or other types of cables or connectors in a system. Clean the floppy drive cables and connectors, the hard disk cables and connectors, and any others you find. Don't forget to clean the edge connectors that are on the disk drive logic boards, as well as the power connectors to the drives.

Cleaning the Keyboard and Mouse

Keyboards and mice are notorious for picking up dirt and garbage. If you ever open up an older keyboard, you will be amazed at the junk you find in there.

To prevent problems, you should periodically clean the keyboard with a vacuum cleaner. An alternative method is to turn the keyboard upside down and shoot it with a can of compressed air. This blows out the dirt and debris that has accumulated inside the keyboard and possibly prevents future problems with sticking keys or dirty keyswitches.

If a particular key is stuck or making intermittent contact, you can soak or spray that switch with contact cleaner. The best way to do this is to first remove the keycap and then spray the cleaner into the switch. This usually does not require complete disassembly of the keyboard. Periodic vacuuming or compressed gas cleaning prevents more serious problems with sticking keys and keyswitches.

Most mice are easy to clean. In most cases, a twist-off locking retainer keeps the mouse ball retained in the body of the mouse. By removing the retainer, the ball drops out. After removing the ball, you should clean it with one of the electronic cleaners. I recommend a pure cleaner instead of a contact cleaner with lubricant because you do not want any lubricant on the mouse ball. Then, wipe off the rollers in the body of the mouse with the cleaner and some swabs.

Monthly cleaning of a mouse in this manner eliminates or prevents skipping or erratic movement. I also recommend a mouse pad for most ball-type mice because the pad prevents the mouse ball from picking up debris from your desk.

Other pointing devices requiring little or no maintenance are the IBM-designed TrackPoint and similar systems introduced by other manufacturers, such as the Glidepoint by Alps. These devices are totally sealed and use pressure transducers to control pointer movement. Optical mice that don't use a ball or roller mechanism also require little or no maintenance. Because they are sealed, cleaning need only be performed externally and is as simple as wiping the device off with a mild cleaning solution to remove oils and other deposits that have accumulated from handling them.

Hard Disk Maintenance

Certain preventive maintenance procedures protect your data and ensure that your hard disk works efficiently. Some of these procedures actually minimize wear and tear on your drive, which prolongs its life. Additionally, a high level of data protection can be implemented by performing some simple commands periodically. These commands provide methods for backing up (and possibly later restoring) critical areas of the hard disk that, if damaged, would disable access to all your files.

Defragmenting Files

Over time, as you delete and save files to a hard disk, the files become fragmented. This means they are split into many noncontiguous areas on the disk. One of the best ways to protect both your hard disk and the data on it is to periodically defragment the files on the disk. This serves two purposes.

One is that by ensuring that all the files are stored in contiguous sectors on the disk, head movement and drive wear and tear is minimized. This has the added benefit of improving the speed at which the drive retrieves files by reducing the head thrashing that occurs every time it accesses a fragmented file.

The second major benefit, and in my estimation the more important of the two, is that in the case of a disaster in which the FATs and root directory are severely damaged, the data on the drive can usually be recovered easily if the files are contiguous. On the other hand, if the files are split up in many pieces across the drive, figuring out which pieces belong to which files is virtually impossible without an intact FAT and directory system. For the purposes of data integrity and protection, I recommend defragmenting your hard disk drives on a monthly basis.

The three main functions in most defragmentation programs are as follows:

- File defragmentation
- File packing (free space consolidation)
- File sorting

Defragmentation is the basic function, but most other programs also add file packing. Packing the files is optional on some programs because it usually takes additional time to perform. This function packs the files at the beginning of the disk so all free space is consolidated at the end of the disk. This feature minimizes future file fragmentation by eliminating any empty holes on the disk. Because all free space is consolidated into one large area, any new files written to the disk are capable of being written in a contiguous manner with no fragmentation.

The last function, file sorting (sometimes called disk optimizing), is not usually necessary and is performed as an option by many defragmenting programs. This function adds a tremendous amount of time to the operation and has little or no effect on the speed at which information is accessed. It can be somewhat beneficial for disaster recovery purposes because you will have an idea of which files came before or after other files if a disaster occurs. Not all defragmenting programs offer file sorting, and the extra time it takes is probably not worth any benefits you will receive. Other programs can sort the order that files are listed in directories, which is a quick and easy operation compared to sorting the file ordering the disk.

Windows 9x/Me/2000/XP include a disk defragmentation program with the operating system, which you can use on any file system the OS supports. For older DOS, Windows 3.x, and some versions of NT, you must purchase a third-party defragmentation program. Norton Utilities includes a disk defragmenter, as do many other utility packages. If you elect to use a third-party product on a Windows 9x/Me/2000/XP system, be certain that it supports the file system you use on your drives. Running a FAT16 defragmentation program on a FAT32 drive can cause severe problems. An excellent third-party defrag program that works on all systems is VOPT by Golden Bow. See the Vendor List on the DVD for more information on these programs.

Before you defragment your disks, you should run a disk repair program, such as ScanDisk or Norton Disk Doctor, even if you are not experiencing any problems. This ensures that your drives are in good working order before you begin the defragmentation process.

Windows 98/Millennium Maintenance Wizard

Windows 98 and Millennium include a Task Scheduler program that enables you to schedule programs for automatic execution at specified times. The Maintenance Wizard walks you through the steps of scheduling regular disk defragmentations, disk error scans, and deletions of unnecessary files. You can schedule these processes to execute during non-working hours, so regular system activities are not disturbed.

Virus Checking

Viruses are a danger to any system, and making scans with an antivirus program a regular part of your preventive maintenance program is a good idea. Many aftermarket utility packages are available that scan for and remove viruses. No matter which of these programs you use, you should perform a scan for virus programs periodically, especially before making hard disk backups. This helps ensure that you catch any potential virus problem before it spreads and becomes a major catastrophe. In addition, selecting an antivirus product from a vendor that provides regular updates to the program's virus signatures is important. The signatures determine which viruses the software can detect and cure, and because new viruses are constantly being introduced, these updates are essential.

Passive Preventive Maintenance Procedures

Passive preventive maintenance involves taking care of the system by providing the best possible environment—both physical and electrical—for the system. Physical concerns are conditions such as ambient temperature, thermal stress from power cycling, dust and smoke contamination, and disturbances such as shock and vibration. Electrical concerns are items such as ESD, power-line noise, and radio-frequency interference. Each of these environmental concerns is discussed in the following sections.

Examining the Operating Environment

Oddly enough, one of the most overlooked aspects of microcomputer preventive maintenance is protecting the hardware—and the sizable financial investment it represents—from environmental abuse. Computers are relatively forgiving, and they are generally safe in an environment that is comfortable for people. Computers, however, are often treated with no more respect than desktop calculators. The result of this type of abuse is many system failures.

Before you set up a new PC, prepare a proper location for it that is free of airborne contaminants such as smoke or other pollution. Do not place your system in front of a window; the computer should not be exposed to direct sunlight or temperature variations. The environmental temperature should be as constant as possible. Power should be provided through properly grounded outlets and should be stable and free from electrical noise and interference. Keep your system away from radio transmitters or other sources of radio frequency energy.

Note

I also don't recommend using computer desks that place the system unit in a sealed cabinet; this is a good way to promote overheating.

Heating and Cooling

Thermal expansion and contraction from ambient temperature changes place stress on a computer system. Therefore, keeping the temperature in your office or room relatively constant is important to the successful operation of your computer system.

Temperature variations can lead to serious problems. You might encounter excessive chip creep, for example. If extreme variations occur over a short period, signal traces on circuit boards can crack and separate, solder joints can break, and contacts in the system can undergo accelerated corrosion. Solid-state components such as chips can be damaged also, and a host of other problems can develop.

Temperature variations can wreak havoc with hard disk drives, too. On some drives, writing to a disk at different ambient temperatures can cause data to be written at different locations relative to the track centers. This can cause read and write problems at a later time.

To ensure that your system operates in the correct ambient temperature, you must first determine your system's specified functional range. Most manufacturers provide data about the correct operating temperature range for their systems. Two temperature specifications might be available, one indicating allowable temperatures during operation and another indicating allowable temperatures under non-operating conditions. IBM, for example, indicates the following temperature ranges as acceptable for most of its systems:

System on: 60–90° Fahrenheit

System off: 50–110° Fahrenheit

For the safety of the disk and the data it contains, avoid rapid changes in ambient temperatures. If rapid temperature changes occur—for example, when a new drive is shipped to a location during the winter and then brought indoors—let the drive acclimate to room temperature before turning it on. In extreme cases, condensation can form on the platters inside the drive head-disk assembly (HDA), which is disastrous for the drive if you turn it on before the condensation has a chance to evaporate. Most drive manufacturers specify a timetable to use as a guide in acclimating a drive to room temperature before operating it. You usually must wait several hours to a day before a drive is ready to use after it has been shipped or stored in a cold environment. Manufacturers normally advise that you leave the drive in its packing until it is acclimated. Removing the drive from a shipping carton when extremely cold increases the likelihood of condensation forming as the drive warms up.

Most office environments provide a stable temperature in which to operate a computer system, but some do not. Be sure to give some consideration to the placement of your equipment.

Power Cycling (On/Off)

As you have just learned, the temperature variations a system encounters greatly stress the system's physical components. The largest temperature variations a system encounters, however, are those that occur during the warm-up period right after you turn on the computer. Powering on a cold system subjects it to the greatest possible internal temperature variations. If you want a system to have the longest and most trouble-free life possible, you should limit the temperature variations in its environment. You can limit the extreme temperature cycling in two simple ways during a cold startup: Leave the system off all the time or leave it on all the time. Of these two possibilities, of course, you probably will want to choose the latter option. Leaving the power on is the best way I know to promote system reliability. If your only concern is system longevity, the simple recommendation is to keep the system unit powered on (or off!) continuously. In the real world, however, there are more variables to consider, such as the cost of electricity, the potential fire hazard of unattended running equipment, and other concerns, as well.

If you think about the way light bulbs typically fail, you can begin to understand how thermal cycling can be dangerous. Light bulbs burn out most often when you first turn them on because the filament must endure incredible thermal stress as it changes temperature, in less than one second, from ambient to several thousands of degrees. A bulb that remains on continuously lasts longer than one that is turned on and off repeatedly.

The place where problems are most likely to occur immediately at power-on is in the power supply. The startup current draw for the system during the first few seconds of operation is very high compared to the normal operating-current draw. Because the current must come from the power supply, the supply has an extremely demanding load to carry for the first few seconds of operation, especially if several disk drives must be started. Motors have an extremely high power-on current draw. This demand often overloads a marginal circuit or component in the supply and causes it to burn or break with a "snap." I have seen several power supplies die the instant a system was powered up. To enable

your equipment to have the longest possible life, try to keep the temperature of solid-state components relatively constant, and limit the number of startups on the power supply. The only way I know to do this is to leave the system on.

Although it sounds like I am telling you to leave all your computer equipment on 24 hours a day, 7 days a week, I no longer recommend this type of operation. A couple of concerns have tempered my urge to leave everything running continuously. One is that an unattended system that is powered on represents a fire hazard. I have seen monitors catch fire after internally shorting and systems whose cooling fans have frozen, causing the power supply and the entire system to overheat. I do not leave any system running in an unattended building. Another problem is wasted electrical power. Many companies have adopted austerity programs that involve turning off lights and other items when not in use. The power consumption of some of today's high-powered systems and accessories is not trivial. Also, an unattended operating system is more of a security risk than one that is powered off and locked.

Realities—such as the fire hazard of unattended systems running during night or weekend hours, security problems, and power-consumption issues—might prevent you from leaving your system on all the time. Therefore, you must compromise. Power on the system only one time daily. Don't power the system on and off several times every day. This good advice is often ignored, especially when several users share systems. Each user powers on the system to perform work on the PC and then powers off the system. These systems tend to have many more problems with component failures.

If you are in a building with a programmable thermostat, you have another reason to be concerned about temperatures and disk drives. Some buildings have thermostats programmed to turn off the heat overnight or over the weekend. These thermostats are programmed also to quickly raise the temperature just before business hours every day. In Chicago, for example, outside temperatures in the winter can dip to –20° (excluding the windchill factor). An office building's interior temperature can drop to as low as 50° during the weekend. When you arrive Monday morning, the heat has been on for only an hour or so, but the hard disk platters might not yet have reached even 60° when you turn on the system. During the first 20 minutes of operation, the disk platters rapidly rise in temperature to 120° or more. If you have an inexpensive stepper motor hard disk and begin writing to the disk at these low temperatures, you are setting yourself up for trouble.

Tip

If you do not leave a system on continuously, at least give it 15 minutes or more to warm up after a cold start before writing to the hard disk. This practice does wonders for the reliability of the data on your disk.

If you do leave your system on for long periods of time, make sure the screen is blank or displays a random image if the system is not in use. The phosphor on the picture tube can burn if a stationary image is left onscreen continuously. Higher-persistence phosphor monochrome screens are most susceptible, and the color displays with low-persistence phosphors are the least susceptible. Most of the monitors used with today's PCs will not show the effect of a screen burn. If you ever have seen a monochrome display with the image of some program permanently burned in—even with the display off—you know what I mean. Look at the monitors that display flight information at the airport; they usually show some of the effects of phosphor burn.

Most modern displays that have power-saving features can automatically enter a standby mode on command by the system. If your system has these power-saving functions, enable them because they help reduce energy costs and preserve the monitor.

Static Electricity

Static electricity or electro-static discharge (ESD) can cause numerous problems within a system. The problems usually appear during the winter months when humidity is low or in extremely dry climates where the humidity is low year-round. In these cases, you might need to take special precautions to ensure that your PC is not damaged. See the section, "ESD Protection Tools," earlier in this chapter, as well as Chapter 21, "Power Supply and Chassis/Case," and Chapter 22 for more information on ESD.

Static discharges outside a system-unit chassis are rarely a source of permanent problems within the system. Usually, the worst possible effect of a static discharge to the case, keyboard, or even a location near the computer is a parity check (memory) error or a system lockup. In some cases, I have been able to cause parity checks or system lockups by simply walking past a PC. Most static-sensitivity problems are caused by improper grounding of the system power. Be sure you always use a three-prong, grounded power cord plugged in to a properly grounded outlet. If you are unsure about the outlet, you can buy an outlet tester, such as those described earlier in this chapter, at most electronics supply or hardware stores for only a few dollars.

Whenever you open a system unit or handle circuits removed from the system, you must be much more careful with static. You can permanently damage a component with a static discharge if the charge is not routed to a ground. I usually recommend handling boards and adapters first by a grounding point such as the bracket to minimize the potential for static damage.

An easy way to prevent static problems is with good power-line grounding, which is extremely important for computer equipment. A poorly designed power-line grounding system is one of the primary causes of poor computer design. The best way to prevent static damage is to prevent the static charge from getting into the computer in the first place. The chassis ground in a properly designed system serves as a static guard for the computer and redirects the static charge safely to the ground. For this ground to be complete, therefore, the system must be plugged in to a properly grounded three-wire outlet.

If the static problem is extreme, you can resort to other measures. One is to use a grounded static mat underneath the computer. Touch the mat first before you touch the computer to ensure that any static charges are routed to ground and away from the system unit's internal parts. If problems still persist, you might want to check out the building's electrical ground. I have seen installations that had three-wire outlets that were rendered useless by the building's ungrounded electrical service.

Power-Line Noise

To run properly, a computer system requires a steady supply of clean, noise-free power. In some installations, however, the power line serving the computer also serves heavy equipment, and the voltage variations resulting from the on/off cycling of this equipment can cause problems for the computer. Certain types of equipment on the same power line also can cause voltage spikes—short, transient signals of sometimes 1,000v or more—that can physically damage a computer. Although these spikes are rare, they can be crippling. Even a dedicated electrical circuit used by only a single computer can experience spikes and transients, depending on the quality of the power supplied to the building or circuit.

During the site-preparation phase of a system installation, you should be aware of these factors to ensure a steady supply of clean power:

- If possible, the computer system should be on its own circuit with its own circuit breaker. This setup does not guarantee freedom from interference, but it helps.
- The circuit should be checked for a good, low-resistance ground, proper line voltage, freedom from interference, and freedom from brownouts (voltage dips).

- A three-wire circuit is a must, but some people substitute grounding-plug adapters to adapt a grounded plug to a two-wire socket. This setup is not recommended; the ground is there for a reason.
- Power-line noise problems increase with the resistance of the circuit, which is a function of wire size and length. So, to decrease resistance, avoid extension cords unless absolutely necessary, and then use only heavy-duty extension cords.
- Inevitably, you will want to plug in other equipment later. Plan ahead to avoid the temptation to connect too many items to a single outlet. If possible, provide a separate power circuit for non–computer-related devices.

Air conditioners, coffee makers, copy machines, laser printers, space heaters, vacuum cleaners, and power tools are some of the worst corrupters of a PC system's power. Any of these items can draw an excessive amount of current and wreak havoc with a PC system on the same electrical circuit. I've seen offices in which all the computers begin to crash at about 9:05 a.m. daily, which is when all the coffee makers are turned on!

Also, try to ensure that copy machines and laser printers do not share a circuit with other computer equipment. These devices draw a large amount of power.

Another major problem in some companies is partitioned offices. Many of these partitions are prewired with their own electrical outlets and are plugged in to one another in a sort of power-line daisy-chain, similar to chaining power strips together. I pity the person in the cubicle at the end of the electrical daisy-chain, who is likely to have very erratic power!

As a real-world example of too many devices sharing a single circuit, I can describe several instances in which a personal computer had a repeating parity check problem. All efforts to repair the system had been unsuccessful. The reported error locations from the parity-check message were inconsistent, which normally indicates a problem with power. The problem could have been the power supply in the system unit or the external power supplied from the wall outlet. This problem was solved one day as I stood watching the system. The parity check message was displayed at the same instant that someone two cubicles away turned on a copy machine. Placing the computers on a separate line solved the problem.

By following the guidelines in this section, you can create the proper power environment for your systems and help ensure trouble-free operation.

Radio-Frequency Interference

Radio-frequency interference (RFI) is easily overlooked as a problem factor. The interference is caused by any source of radio transmissions near a computer system. Living next door to a 50,000-watt commercial radio station is one sure way to get RFI problems, but less-powerful transmitters can cause problems, too. I know of many instances in which cordless telephones have caused sporadic random keystrokes to appear, as though an invisible entity were typing on the keyboard. I also have seen RFI cause a system to lock up. Solutions to RFI problems are more difficult to state because every case must be handled differently. Sometimes, simply moving the system eliminates the problem because radio signals can be directional in nature. At other times, you must invest in specially shielded cables for external devices, such as the keyboard and the monitor.

One type of solution to an RFI noise problem with cables is to pass the cable through a toroidal iron core, a doughnut-shaped piece of iron placed around a cable to suppress both the reception and transmission of electromagnetic interference (EMI). Many monitors include a toroid on the cable that connects to the computer. If you can isolate an RFI noise problem in a particular cable, you often can solve the problem by passing the cable through a toroidal core. Because the cable must pass through

the center hole of the core, it often is difficult, if not impossible, to add a toroid to a cable that already has end connectors installed.

Radio Shack sells a special snap-together toroid designed specifically to be added to cables already in use. This toroid looks like a thick-walled tube that has been sliced in half. You simply lay the cable in the center of one of the halves, and snap the other half over the first. This type of construction makes adding the noise-suppression features of a toroid to virtually any existing cable easy.

The best, if not the easiest, way to eliminate an RFI problem is to correct it at the source. It is unlikely that you'll be able to convince the commercial radio station near your office to shut down, but if you are dealing with a small radio transmitter that is generating RFI, sometimes you can add a filter to the transmitter that suppresses spurious emissions. Unfortunately, problems sometimes persist until the transmitter is either switched off or moved some distance away from the affected computer.

Dust and Pollutants

Dirt, smoke, dust, and other pollutants are bad for your system. The power-supply fan carries airborne particles through your system, and they collect inside. If your system is used in an extremely harsh environment, you might want to investigate some of the industrial systems on the market designed for harsh conditions.

Many companies make special hardened versions of their systems for harsh environments. Industrial systems usually use a different cooling system from the one used in regular PCs. A large cooling fan is used to pressurize the case rather than depressurize it. The air pumped into the case passes through a filter unit that must be cleaned and changed periodically. The system is pressurized so that no contaminated air can flow into it; air flows only outward. The only way air can enter is through the fan and filter system.

These systems also might have special keyboards impervious to liquids and dirt. Some flat-membrane keyboards are difficult to type on, but are extremely rugged; others resemble the standard types of keyboards but have a thin, plastic membrane that covers all the keys. You can add this membrane to normal types of keyboards to seal them from the environment.

A new breed of humidifier can cause problems with computer equipment. This type of humidifier uses ultrasonics to generate a mist of water sprayed into the air. The extra humidity helps cure problems with static electricity resulting from a dry climate, but the airborne water contaminants can cause many problems. If you use one of these systems, you might notice a white, ash-like deposit forming on components. The deposit is the result of abrasive and corrosive minerals suspended in the vaporized water. If these deposits collect on the system components, they can cause all kinds of problems. The only safe way to run one of these ultrasonic humidifiers is to use distilled water. If you use a humidifier, be sure it does not generate these deposits.

If you do your best to keep the environment for your computer equipment clean, your system will run better and last longer. Also, you will not have to open up your unit as often for complete preventive maintenance cleaning.

Basic Troubleshooting Guidelines

This section lists basic and general system troubleshooting procedures and guidelines. For specific procedures for troubleshooting a component in the system, use Appendix C, "Troubleshooting Index," as a quick reference for finding the chapter or section dedicated to that part of the PC.

Before starting any system troubleshooting, a few basic steps should be performed to ensure a consistent starting point and to enable isolating the failed component:

1. Turn off the system and any peripheral devices. Disconnect all external peripherals from the system, except for the keyboard and video display.
2. Make sure the system is plugged in to a properly grounded power outlet.
3. Make sure the keyboard and video displays are connected to the system. Turn on the video display, and turn up the brightness and contrast controls to at least two-thirds of the maximum. Some displays have onscreen controls that might not be intuitive. Consult the display documentation for more information on how to adjust these settings. If you can't get any video display but the system seems to be working, try moving the card to a different slot (not possible with AGP adapters) or try a different video card or monitor.
4. To enable the system to boot from a hard disk, make sure no floppy disk is in the floppy drive. Or put a known good bootable floppy with DOS or diagnostics on it in the floppy drive for testing.
5. Turn on the system. Observe the power supply, chassis fans (if any), and lights on either the system front panel or power supply. If the fans don't spin and the lights don't light, the power supply or motherboard might be defective.
6. Observe the power on self test (POST). If no errors are detected, the system beeps once and boots up. Errors that display onscreen (*nonfatal* errors) and that do not lock up the system display a text message that varies according to BIOS type and version. Record any errors that occur and refer to the DVD accompanying this book for a list of BIOS error codes for more information on any specific codes you see. Errors that lock up the system (*fatal* errors) are indicated by a series of audible beeps. Refer to the DVD for a list of beep error codes.
7. Confirm that the operating system loads successfully.

Note

The Technical Reference section of the DVD accompanying this book contains an exhaustive listing of BIOS error codes, error messages, and beep codes for BIOSes from Phoenix, AMI, Award, Microid Research, and IBM.

Problems During the POST

Problems that occur during the POST are usually caused by incorrect hardware configuration or installation. Actual hardware failure is a far less-frequent cause. If you have a POST error, check the following:

1. Are all cables correctly connected and secured?
2. Are the configuration settings correct in Setup for the devices you have installed? In particular, ensure the processor, memory, and hard drive settings are correct.
3. Are all drivers properly installed?
4. Are switches and jumpers on the baseboard correct, if changed from the default settings?
5. Are all resource settings on add-in boards and peripheral devices set so that no conflicts exist—for example, two add-in boards sharing the same interrupt?
6. Is the power supply set to the proper input voltage (110/220v)?
7. Are adapter boards and disk drives installed correctly?
8. Is a keyboard attached?
9. Is a bootable hard disk (properly partitioned and formatted) installed?

10. Does the BIOS support the drive you have installed, and if so, are the parameters entered correctly?
11. Is a bootable floppy disk installed in drive A:?
12. Are all memory SIMMs or DIMMs installed correctly? Try reseating them.
13. Is the operating system properly installed?

Hardware Problems After Booting

If problems occur after the system has been running, and without having made any hardware or software changes, a hardware fault possibly has occurred. Here is a list of items to check in that case:

1. Try reinstalling the software that has crashed or refuses to run.
2. Try clearing CMOS RAM and running Setup.
3. Check for loose cables, a marginal power supply, or other random component failures.
4. A transient voltage spike, power outage, or brownout might have occurred. Symptoms of voltage spikes include a flickering video display, unexpected system reboots, and the system not responding to user commands. Reload the software and try again.
5. Try reseating the memory modules (SIMMs, DIMMs, or RIMMs).

Problems Running Software

Problems running application software (especially new software) are usually caused by or related to the software itself, or are due to the fact that the software is incompatible with the system. Here is a list of items to check in that case:

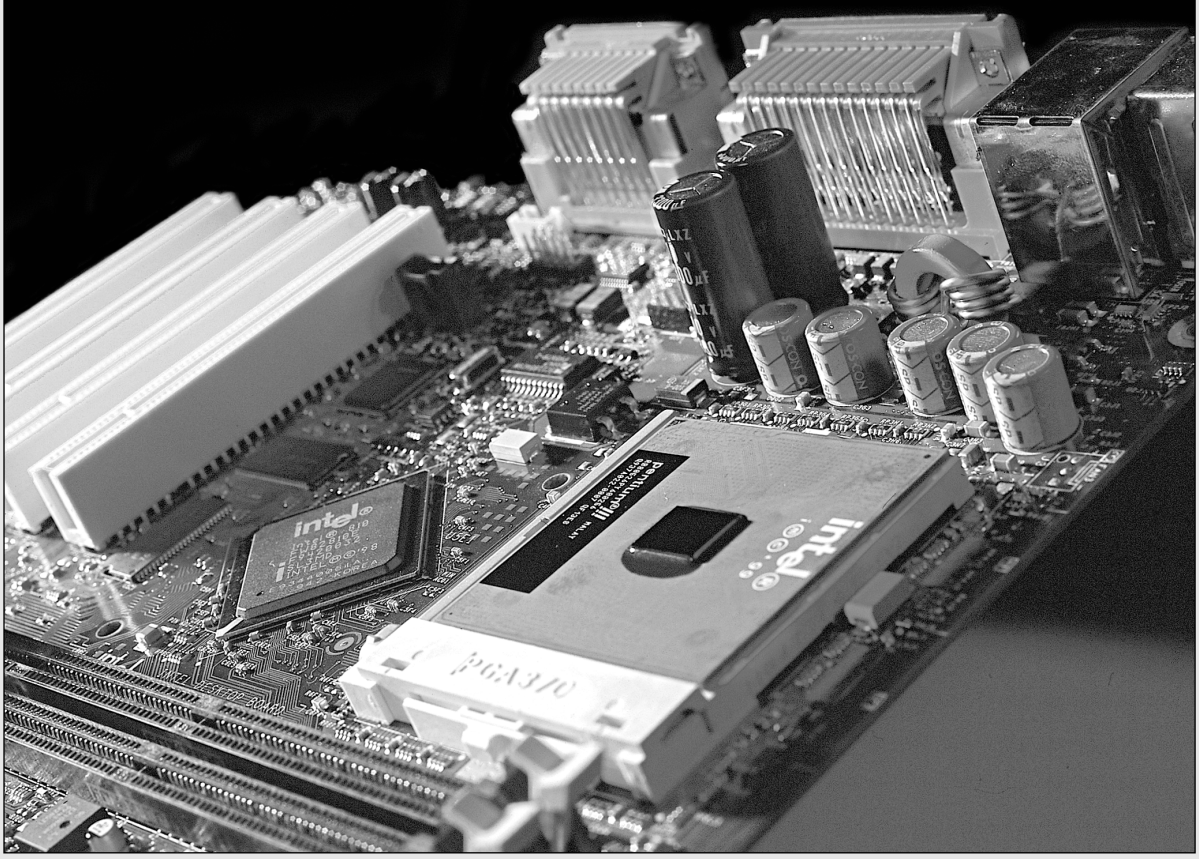
1. Does the system meet the minimum hardware requirements for the software? Check the software documentation to be sure.
2. Check to see that the software is correctly installed. Reinstall if necessary.
3. Check to see that the latest drivers are installed.
4. Scan the system for viruses using the latest antivirus software.

Problems with Adapter Cards

Problems related to add-in boards are usually related to improper board installation or resource (interrupt, DMA, or I/O address) conflicts. Chapter 4, "Motherboards and Buses," has a detailed discussion of these system resources, what they are, how to configure them, and how to troubleshoot them. Also be sure to check drivers for the latest versions and ensure that the card is compatible with your system and the operating system version you are using.

Sometimes adapter cards can be picky about which slot they are running in. Despite the fact that, technically, a PCI or ISA adapter should be able to run in any of the slots, minor timing or signal variations sometimes occur from slot to slot. I have found on numerous occasions that simply moving a card from one slot to another can make a failing card begin to work properly. Sometimes moving a card works just by the inadvertent cleaning (wiping) of the contacts that takes place when removing and reinstalling the card, but in other cases I can duplicate the problem by inserting the card back into its original slot. When all else fails, try moving the cards around!

Caution



Note that PCI cards become slot specific after their drivers are installed. By this I mean that if you move the card to another slot, the plug-and-play resource manager sees it as if you have removed one card and installed a new one. You therefore must install the drivers all over again for that card. Don't move a PCI card to a different slot unless you are prepared with all the drivers at hand to perform the driver installation. ISA cards don't share this quirk because the system is not aware of which slot an ISA card is in.

One common problem I've seen cropping up lately is with people installing newer PCI video cards in older systems with PCI slots. The PCI bus has gone through several revisions; most older slots are "2.0" type, and most newer cards need "2.1" or later PCI slots. The version of PCI your system has is dictated by the motherboard chipset. If you install a newer video or other PCI card that requires 2.1 slots in a system with 2.0 slots, often the system won't boot up or operate at all.

If you check the chipset reference information in Chapter 4, you might be able to determine which revision of PCI slots your motherboard has by knowing which chipset it has. If this is your problem, the only solution is to change either the card or motherboard so that they are both compatible.

CHAPTER 24

File Systems and Data Recovery

File Systems

Physically, the hard disks and other media provide the basic technology for storing data. Logically, however, the file system provides the hierarchical structure of volumes and directories in which you store individual files and the organizational model that enables the system to locate data anywhere on a given disk or drive. File systems typically are an integrated part of an operating system (OS), and many of the newer OSes provide support for several file systems from which you can choose.

Several file systems are available from which to choose in a modern PC. Each file system has specific limitations, advantages, and disadvantages, and which ones you use can also be limited by the operating system you choose. Not all operating systems support all the file systems.

The primary file systems to choose from today include

- File allocation table (FAT), which includes FAT12, FAT16, and FAT32
- New Technology File System (NTFS)

Although other file systems, such as OS/2's High Performance File System (HPFS), are in use on PCs, these are the two you're most likely to find on a Windows-based PC. Consequently, this chapter focuses mainly on FAT and NTFS.

File Allocation Table

The most commonly used file systems today are based on a file allocation table (FAT), which keeps track of the data stored in each cluster on a disk. Several varieties of the FAT system exist, called FAT12, FAT16, and FAT32—all of which are differentiated by the number of digits used in the allocation table numbers. In other words, FAT16 uses 16-bit numbers to keep track of data clusters, FAT32 uses 32-bit numbers, and so on. The various FAT systems are used as follows:

- *FAT12.* Used on all volumes smaller than 16MB (for example, floppies).
- *FAT16.* Used on volumes from 16MB through 2GB by MS-DOS and most versions of Windows. Windows NT, Windows 2000, and Windows XP support FAT16 volumes as large as 4GB.
- *FAT32.* Optionally used on volumes from 512MB through 2TB.

FAT12 and FAT16 are the file systems originally used by DOS and Windows and are supported by virtually every other PC operating system in use today.

FAT32 is supported by Windows 95B and later versions, including 95C, 98, Me, Windows 2000, and Windows XP (Windows 2000 and Windows XP also support NTFS). Although all PC operating systems I am aware of support at least FAT12 and FAT16, some have support for non-FAT file systems as well. Windows NT introduced the NTFS, which is unique to NT-based operating systems (including Windows 2000 and Windows XP) and is not supported by Windows 9x/Me. OS/2 1.2 introduced the High Performance File System, which is unique to OS/2, although NT versions 3.x also support it. Most PC drives or volumes today are formatted under one of the FAT file systems.

This chapter examines these file systems in more detail. Because of the popularity of the FAT file systems, they are emphasized, although the additional capabilities provided by HPFS or NTFS are also discussed.

To manage files on a disk and enable all applications to see a consistent interface to the file system no matter what type of storage hardware is being used, the operating system creates several structures on the disk. These structures are the same for any OS that supports the FAT file system, including Windows 9x, Windows NT, and Windows 2000. The following list shows all the structures and areas FAT uses to manage a disk, in roughly the same order in which they appear on the media:

- Master and extended partition boot records (sectors)
- Volume boot record
- Root directory
- File allocation tables
- Clusters (allocation units in the data area)
- Diagnostic read-and-write cylinder

All these structures are detailed later in this section. A hard disk has all these disk-management structures, and a floppy disk has all but the master and extended partition boot records and diagnostic cylinder. The volume boot record through data area structures are repeated for each partition or volume on a drive. These structures are created on hard disk drives or other high-capacity media by the FDISK program included with all operating systems. You can't use FDISK on a floppy disk because floppy disks can't be partitioned. Figure 24.1 is a simple diagram showing the relative locations of these FAT disk-management structures on a 2111MB Western Digital hard disk.

Note

Some removable cartridge drives, such as the SuperDisk (LS-120) and Iomega Zip drive, function like high-capacity floppy disk drives. They lack a master boot record (MBR) and diagnostic cylinder and can't be partitioned like hard disk drives. Other higher-capacity removable drives, such as the Iomega Jaz, can be partitioned like a hard disk drive.

Figure 24.1 shows the placement and arrangement of the file-management structures on a typical drive. This particular example uses a Western Digital Caviar AC12100, but all PC hard drives using the FAT file system are similar except for the number of cylinders.

Each disk area has a purpose and function. If one of these special areas is damaged, serious consequences can result. Damage to one of these sensitive structures usually causes a domino effect, limiting access to other areas of the disk or causing further problems in using the disk. For example, the OS normally can't access a drive at all if the MBR is corrupted. Therefore, you should understand these data structures well enough to be able to repair them when necessary. Rebuilding these special tables and areas of the disk is essential to the art of data recovery.

Master Boot Record

The first PC OS to support hard disks, DOS 2.0 released in 1983, was also the first to introduce the 16-bit FAT and the capability to partition a drive. *Partitioning* is basically dividing the drive into multiple volumes. One concept easily misunderstood is that all drives that *can* be partitioned *must* be partitioned; that is, you have to partition the drive even if you are going to set it up with only one partition. Another name for a partition is a *logical volume* because the partition shows up as an additional drive letter or volume to the OS.

Although the primary use for partitioning today is to divide a single drive into multiple volumes for use by the same OS, originally it was intended to allow multiple different OSes, each with different file systems, to coexist on a single drive. This multi-OS capability still exists today; however, additional aftermarket utilities often are required to manage and boot from multiple OSes on a single machine.

To use a hard disk with different operating systems, you can create partitions to logically divide the disk. You can, for example, use FDISK to create one or more FAT partitions for use with DOS or Windows 9x and leave the rest of the disk storage area for use by another OS's file system, such as NTFS or Linux. Each of the FAT partitions appear to the OS as a separate drive letter. The unused or

non-FAT partitions are listed as such in Windows 9x/Me or DOS FDISK and are ignored by the disk management and other tools in these operating systems.

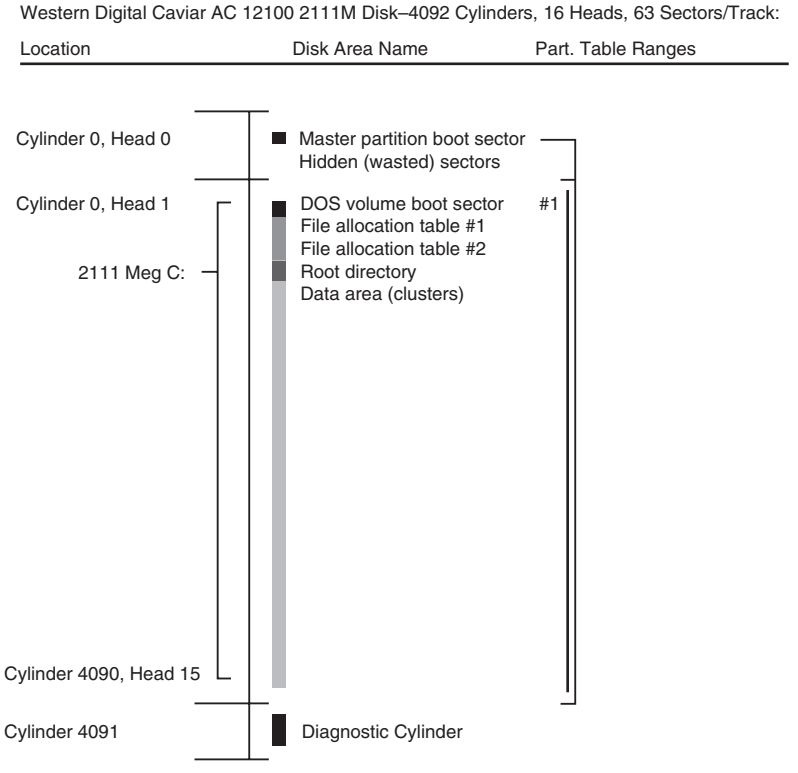


Figure 24.1 FAT file-management structures on a typical drive.

◀◀ For more information about creating and formatting partitions, see Chapter 14, "Physical Drive Installation and Configuration," p. 813.

Information about each of the partitions on the disk is stored in a partition (or volume) boot record at the beginning of each partition. Additionally, a main table lists the partitions embedded in the master partition boot record.

The master partition boot record (or master boot sector) is always located in the first sector of the entire disk (cylinder 0, head 0, sector 1) and consists of the following structures:

- *Master partition table.* Contains a list of the partitions on the disk and the locations of their volume boot records. This table is very small and can contain only four entries at the most. Therefore, to accommodate more partitions, operating systems such as DOS can divide a single extended partition into multiple logical volumes.
- *Master boot code.* A small program that is executed by the system BIOS, the main function of which is to pass control of the system to the partition that has been designated as active (or bootable).

Primary and Extended FAT Partitions

Most OSes are designed to support up to 24 partitions on a single hard disk drive (represented by the drive letters C:–Z:), but the partition table in the master partition boot record can have a maximum of only four entries. To resolve this discrepancy, the FDISK program enables you to create two types of FAT partitions: a primary partition and an extended partition. The first FAT partition you create on a disk should be the *primary*, which is listed in the master partition table and appears to the operating system as a single drive letter.

An *extended* partition is listed in the master partition table like the primary is, but it differs in that you can use its disk space to create multiple logical partitions, or *volumes*. You can create only one extended partition on a single drive, meaning that typically there will never be more than two entries in the master partition table devoted to FAT volumes.

The logical volumes you create in the extended partition appear as separate drive letters to the operating system, but they are not listed in the master partition table. Logical volumes can't be active partitions and are therefore not bootable. You can create up to 23 volumes out of a single extended partition (assuming that you already have created a primary FAT partition, which brings the total to 24).

Each of the logical partitions (or volumes) in an extended partition includes an extended partition table that contains information about that volume. The master partition table's entry for the extended partition contains a reference to the first volume's extended partition table. This table in turn contains a reference detailing the location of the second volume's table. This chain of references continues, linking all the volumes in the extended partition to the master partition table.

Of course, few people have any reason to create 24 FAT partitions on a single disk drive, but the extended partition makes it possible to exceed the four-entry limitation of the master partition table.

Because the master boot record contains the first program the system executes when you boot a PC, it is frequently a target for creators of computer viruses. A virus that infects or destroys the master boot record can make it impossible for the BIOS to find the active partition, thus preventing the operating system from loading. Because the master boot record contains the first program executed by the system, a virus stored there loads before any antivirus code can detect it. To remove a master boot record virus, you must first boot the system from a clean, uninfected disk, such as a floppy disk, bootable CD-ROM, or high-capacity disk, and then run an antivirus program.

Each partition on a disk contains a volume boot record as its first sector, which is listed in the master partition table. With the FDISK utility, you can designate a single partition as active (or bootable). The master partition boot record causes the active partition's volume boot record to receive control whenever the system is started or reset. You can also create additional disk partitions for Novell NetWare, Windows NT/2000's NTFS, OS/2's HPFS, AIX (Unix), XENIX, or other file systems, using disk utilities provided with the operating systems that support them. These partitions are listed in the master partition table, even though they might use different structures within the partition. If you install multiple operating systems on a single system, a boot manager program (which might be included with the operating systems or installed separately) is needed to allow you to select which partition to make active each time you boot the system.

However, you can't access the data stored on these foreign operating system partitions with DOS. In some cases, you can't access FAT partitions using other operating systems either, although OS/2 and Windows NT/2000/XP do support FAT in addition to their own file systems: HPFS (OS/2) and NTFS (NT/2000/XP). You must create at least one partition on a hard disk for it to be accessible by an operating system. Creating a partition adds an entry to the master partition table.

Table 24.1 shows the format of the master boot record and its partition tables. The table lists the fields in each of the master partition table's four entries, the location on the disk where each field begins (the offset), and its length. Some of the fields are stored as *dwords*—four bytes read in reverse order—because of the internal structure of the Intel processors.

Table 24.1 Master Boot Record (Partition Tables)

Master Partition Table Entry #1		
Offset	**Length**	**Description**
1BEh 446	1 byte	Boot indicator byte (80h = active, else 00h)
1BFh 447	1 byte	Starting head (or side) of partition
1C0h 448	16 bits	Starting cylinder (10 bits) and sector (6 bits)
1C2h 450	1 byte	System indicator byte (see Table 24.2)
1C3h 451	1 byte	Ending head (or side) of partition
1C4h 452	16 bits	Ending cylinder (10 bits) and sector (6 bits)
1C6h 454	1 dword	Relative sector offset of partition
1CAh 458	1 dword	Total number of sectors in partition
Partition Table Entry #2		
Offset	**Length**	**Description**
1CEh 462	1 byte	Boot indicator byte (80h = active, else 00h)
1CFh 463	1 byte	Starting head (or side) of partition
1D0h 464	16 bits	Starting cylinder (10 bits) and sector (6 bits)
1D2h 466	1 byte	System indicator byte (see Table 24.2)
1D3h 467	1 byte	Ending head (or side) of partition
1D4h 468	16 bits	Ending cylinder (10 bits) and sector (6 bits)
1D6h 470	1 dword	Relative sector offset of partition
1DAh 474	1 dword	Total number of sectors in partition
Partition Table Entry #3		
Offset	**Length**	**Description**
1DEh 478	1 byte	Boot indicator byte (80h = active, else 00h)
1DFh 479	1 byte	Starting head (or side) of partition
1E0h 480	16 bits	Starting cylinder (10 bits) and sector (6 bits)
1E2h 482	1 byte	System indicator byte (see Table 24.2)
1E3h 483	1 byte	Ending head (or side) of partition
1E4h 484	16 bits	Ending cylinder (10 bits) and sector (6 bits)
1E6h 486	1 dword	Relative sector offset of partition
1EAh 490	1 dword	Total number of sectors in partition

Table 24.1 Continued

Partition Table Entry #4		
Offset	**Length**	**Description**
1EEh 494	1 byte	Boot indicator byte (80h = active, else 00h)
1EFh 495	1 byte	Starting head (or side) of partition
1F0h 496	16 bits	Starting cylinder (10 bits) and sector (6 bits)
1F2h 498	1 byte	System indicator byte (see Table 24.2)
1F3h 499	1 byte	Ending head (or side) of partition
1F4h 500	16 bits	Ending cylinder (10 bits) and sector (6 bits)
1F6h 502	1 dword	Relative sector offset of partition
1FAh 506	1 dword	Total number of sectors in partition
Signature Bytes		
Offset	**Length**	**Description**
1FEh 510	2 bytes	Boot sector signature (55AAh)

A word equals 2 bytes read in reverse order, and a dword equals two words read in reverse order.

The data in the partition table entries tells the system where each partition starts and ends on the drive, how big it is, whether it is bootable, and which type of file system is contained in the partition. Each entry in the master partition table contains a system indicator byte that identifies the file system type used in the partition referenced by that entry. Table 24.2 shows the standard values and meanings of the system indicator bytes, and Table 24.3 lists the nonstandard values.

Table 24.2 Standard System Indicator Byte Values

Value	Partition Type	Translation Mode	Partition Size
00h	None	—	—
01h	Primary FAT12	CHS	0–15MB
04h	Primary FAT16	CHS	16MB–32MB
05h	Extended	CHS	16MB–32MB
06h	Primary FAT16 (also called BigDOS)	CHS	32MB–2GB
07h	NTFS/HPFS/QNX (also Advanced Unix)	All	All
0Ah	OS/2 Bootmanager	All	All
0Bh	Primary FAT32	LBA	512MB–2TB
0Ch	Primary FAT32	LBA	512MB–2TB
0Eh	Primary FAT16	LBA	32MB–2GB
0Fh	Extended	LBA	32MB–2GB

CHS = Cylinder head sector

LBA = Logical block address

Table 24.3 Nonstandard System Indicator Byte Values

Value	Partition Type	Value	Partition Type
02h	MS-XENIX Root	75h	IBM PC/IX
03h	MS-XENIX usr	80h	Minix v.1.1–v1.4a
08h	AIX File System Boot	81h	Minix v1.4b-up or Linux
09h	AIX Data	82h	Linux swap file
12h	Compaq diagnostics	83h	Linux native file system
40h	ENIX 80286	93h	Amoeba file system
50h	OnTrack Disk Manager read-only DOS	94h	Amoeba bad block table
51h	OnTrack Disk Manager read/write DOS	B7h	BSDI file system (secondary swap)
52h	CP/M or Microport System V/386	B8h	BSDI file system (secondary file system)
54h	OnTrack Disk Manager non-DOS	DBh	DR Concurrent DOS/CPM-86/CTOS
55h	Micro House EZ-Drive non-DOS	E1h	SpeedStor 12-bit FAT extended
56h	Golden Bow Vfeature Deluxe	E4h	SpeedStor 16-bit FAT extended
61h	Storage Dimensions SpeedStor	F2h	DOS 3.3+secondary
63h	IBM 386/ix or Unix System V/386	F4h	SpeedStor primary
64h	Novell NetWare 286	FEh	LANstep
65h	Novell NetWare 386	FFh	Unix/Xenix Bad Block Table Partition

These values can be useful for somebody trying to manually repair a partition table using a disk editor such as the Diskedit program included with Norton Utilities.

Undocumented FDISK

FDISK is a very powerful program. In DOS 5 and later versions, including Windows 9x/Me, it gained some additional capabilities (Windows NT/2000/XP use the Disk Administrator to perform the functions of FDISK and FORMAT). Unfortunately, these capabilities were never documented in any of the Microsoft documentation for Windows or DOS. The most important undocumented parameter in FDISK is the `/MBR` (master boot record) parameter, which causes FDISK to rewrite the master boot record code area, leaving the partition table area intact.

The `/MBR` parameter is tailor-made for eliminating boot sector virus programs that infect the master partition boot record (cylinder 0, head 0, sector 1) of a hard disk. To use this feature, enter the following:

```
FDISK /MBR
```

FDISK then rewrites the boot record code, leaving the partition tables intact. This should not cause any problems on a normally functioning system, but just in case, I recommend backing up the partition table information to floppy disk before trying it. You can do this by using a third-party product such as Norton Utilities.

Be aware that using FDISK with the `/MBR` switch overwrites the partition tables if the two signature bytes at the end of the sector (55AAh) are damaged. This situation is highly unlikely, however. In fact, if these signature bytes were damaged, you would know—the system would not boot and would act as though there were no partitions at all. If you are unable to access your hard disk after booting from a clean floppy or removable-media drive, your system might be infected with a boot sector virus. You should scan for viruses with an up-to-date antivirus program and use it to guide repair.

Caution

Also note that **FDISK/MBR** should be used only on systems using the normal master boot record structure. If a disk-management program such as Disk Manager, EZ-Drive, MaxBlast, Data Lifeguard Tools, or similar is being used to allow your system to access the drive's full capacity, do not use **FDISK/MBR** because these programs use a modified MBR for disk access. Using **FDISK/MBR** will wipe out the changes they made to your drive and could make your data inaccessible.

The equivalent Windows NT/2000 Recovery Console feature to DOS/Windows 9x/Me's **FDISK/MBR** is called **FIXMBR**. The Recovery Console equivalent to FDISK is **DISKPART**. For details on the use of these commands, type **HELP** after loading the Recovery Console.

Volume Boot Records

The volume boot record is the first sector on any area of a drive addressed as a partition or volume (or logical DOS disk). On a floppy disk or removable cartridge (such as a Zip disk), for example, this sector is the first one on the disk because DOS recognizes the disk as a volume without the need for partitioning. On a hard disk, the volume boot record or sectors are located as the first sector within any disk area allocated as a nonextended partition, or any area recognizable as a logical volume. Refer to Figure 24.1 for an idea of the physical relationship between this volume boot record and the other data structures on a disk. The volume boot record resembles the master partition boot record in that it contains two elements, which are as follows:

- *Disk parameter block*. Sometimes called the media parameter block, the disk parameter block contains specific information about the volume, such as its size, the number of disk sectors it uses, the size of its clusters, and the volume label name.
- *Volume boot code*. The program that begins the process of loading the operating system. For DOS and Windows 9x/Me systems, this is the **IO.SYS** file.

Either the system ROM BIOS for floppy disks or the master partition boot record on a hard disk loads the volume boot record of the active partition on a disk. The program code in the volume boot record is given control of the system; it performs some tests and then attempts to load the first system file (in DOS/Windows this is **IO.SYS**). The volume boot record, similar to the master boot record, is transparent to the running system; it is outside the data area of the disk on which files are stored.

Note

Many of today's systems are capable of booting from drives other than standard floppy disk and hard disk drives. In these cases, the system BIOS must specifically support the boot drive. For example, some BIOS products enable you to select an ATAPI CD-ROM as a boot device, in addition to the floppy and hard disk drives.

Other types of removable media, such as Zip cartridges and LS-120 disks, can also be made bootable. When the BIOS properly supports it, an LS-120 drive can replace the existing floppy disk drive as drive A:. Some of the latest systems even support booting from USB drives.

On a FAT partition, you create a volume boot record with the **FORMAT** command (high-level format) included with DOS and Windows 9x. Hard disks on FAT systems have a volume boot record at the beginning of every DOS logical drive area allocated on the disk, in both the primary and extended partitions. Although all the logical drives contain the program area as well as a data table area, only the program code from the volume boot record in the active partition on a hard disk is executed. The others are read by the operating system files during bootup to obtain their data tables and determine the volume parameters.

The volume boot record contains program code and data. The single data table in this sector is called the media parameter block or disk parameter block. The operating system needs the information this table contains to verify the capacity of the disk volume as well as the location of important structures, such as the FAT. The format of this data is very specific.

Table 24.4 shows the format and layout of the DOS boot record (DBR), including the location of each field within the record (the offset) in both hexadecimal and decimal notation and the length of each field.

Table 24.4 DOS Boot Record Format Offset

Hex	Dec	Field Length	Description
00h	0	3 bytes	Jump instruction to boot program code
03h	3	8 bytes	OEM name and DOS version (IBM 5.0)
0Bh	11	1 word	Bytes/sector (usually 512)
0Dh	13	1 byte	Sectors/cluster (must be a power of 2)
0Eh	14	1 word	Reserved sectors (boot sectors, usually 1)
10h	16	1 byte	FAT copies (usually 2)
11h	17	1 word	Maximum root directory entries (usually 512)
13h	19	1 word	Total sectors (if partition <= 32MB, else 0)
15h	21	1 byte	Media descriptor byte (F8h for hard disks)
16h	22	1 word	Sectors/FAT
18h	24	1 word	Sectors/track
1Ah	26	1 word	Number of heads
1Ch	28	1 dword	Hidden sectors (if partition <= 32MB, 1 word only)
		For DOS 4.0 or Higher Only, Else 00h	
Hex	**Dec**	**Field Length**	**Description**
20h	32	1 dword	Total sectors (if partition > 32MB, else 0)
24h	36	1 byte	Physical drive no. (00h = floppy, 80h = hard disk)
25h	37	1 byte	Reserved (00h)
26h	38	1 byte	Extended boot record signature (29h)
27h	39	1 dword	Volume serial number (32-bit random number)
2Bh	43	11 bytes	Volume label (NO NAME stored if no label)
36h	54	8 bytes	File system ID (FAT12 or FAT16)
		For All Versions of DOS	
Hex	**Dec**	**Field Length**	**Description**
3Eh	62	448 bytes	Boot program code
1FEh	510	2 bytes	Signature bytes (55AAh)

A word is 2 bytes read in reverse order, and a dword is two words read in reverse order.

Root Directory

A *directory* is a simple database containing information about the files stored on a FAT partition. Each record in this database is 32 bytes long, with no delimiters or separating characters between the fields

or records. A directory stores almost all the information that the operating system knows about a file, including the following:

- *Filename and extension.* The eight-character name and three-character extension of the file. The dot between the name and the extension is implied but not included in the entry.

Note

To see how Windows 9x/Me extends filenames to allow 255 characters within the 8.3 directory structure, see the section "VFAT and Long Filenames," later in this chapter.

- *File attribute byte.* The byte containing the flags representing the standard DOS file attributes, using the format shown in Table 24.6.
- *Date/Time of last change.* The date and time that the file was created or last modified.
- *File size.* The size of the file, in bytes.
- *Link to start cluster.* The number of the cluster in the partition where the beginning of the file is stored. To learn more about clusters, see the section "Clusters (Allocation Units)," later in this chapter.

Other information exists that a directory does not contain about a file. This includes where the rest of its clusters in the partition are located and whether the file is contiguous or fragmented. This information is contained in the FAT.

Two basic types of directories exist: the root directory (also called the root folder) and subdirectories (also called folders). Any given volume can have only one root directory. The root directory is always stored on a disk in a fixed location immediately following the two copies of the FAT. Root directories vary in size because of the different types and capacities of disks, but the root directory of a given disk is fixed. Using the `FORMAT` command creates a root directory that has a fixed length and can't be extended to hold more entries. The root directory entry limits are shown in Table 24.5. Subdirectories are stored as files in the data area of the disk and can grow in size dynamically; therefore, they have no fixed length limits.

Table 24.5 Root Directory Entry Limits

Drive Type	Maximum Root Directory Entries
Hard disk	512
1.44MB floppy disk	224
2.88MB floppy disk	448
Jaz and Zip	512
LS-120	512

Note

Two advantages of the FAT32 file system are that the root directory can be located anywhere on the disk and it can have an unlimited number of entries. FAT32 is discussed in more detail later in this chapter.

Every directory, whether it is the root directory or a subdirectory, is organized in the same way. Entries in the directory database store important information about individual files and how files are

named on the disk. The directory information is linked to the FAT by the starting cluster entry. In fact, if no file on a disk were longer than one single cluster, the FAT would be unnecessary. The directory stores all the information needed by DOS to manage the file, with the exception of the list of clusters the file occupies other than the first one. The FAT stores the remaining information about the other clusters the file occupies.

To trace a file on a disk, use a disk editor, such as the DISKEDIT program that comes with the Norton Utilities. Start by looking up the directory entry to get the information about the starting cluster of the file and its size. Then, using the appropriate editor commands, go to the FAT where you can follow the chain of clusters the file occupies until you reach the end of the file. By using the directory and FAT in this manner, you can visit all the clusters on the disk that are occupied by the file. This type of technique can be useful when these entries are corrupted and when you are trying to find missing parts of a file.

FAT directory entries are 32 bytes long and are in the format shown in Table 24.6, which shows the location (or offset) of each field within the entry (in both hexadecimal and decimal form) and the length of each field.

Table 24.6 FAT Directory Format

Offset (Hex)	Offset (Dec)	Field Length	Description
00h	0	8 bytes	Filename
08h	8	3 bytes	File extension
0Bh	11	1 byte	File attributes
0Ch	12	10 bytes	Reserved (00h)
16h	22	1 word	Time of creation
18h	24	1 word	Date of creation
1Ah	26	1 word	Starting cluster
1Ch	28	1 dword	Size in bytes

Filenames and extensions are left-justified and padded with spaces, (which are represented as ASCII 32h bytes). In other words, if your filename is "AL", it is really stored as "AL------", where the hyphens are spaces. The first byte of the filename indicates the file status for that directory entry, shown in Table 24.7.

Table 24.7 Directory Entry Status Byte (First Byte)

Hex	File Status
00h	Entry never used; entries past this point not searched.
05h	Indicates that the first character of the filename is actually E5h.
E5h	s (lowercase sigma). Indicates that the file has been erased.
2Eh	. (period). Indicates that this entry is a directory. If the second byte is also 2Eh, the cluster field contains the cluster number of the parent directory (0000h, if the parent is the root).

A word is 2 bytes read in reverse order, and a dword is two words read in reverse order.

Table 24.8 describes the FAT directory file attribute byte. Attributes are 1-bit flags that control specific properties of a file, such as whether it is hidden or designated as read-only. Each flag is individually

activated (1) or deactivated (0) by changing the bit value. The combination of the eight bit values can be expressed as a single hexadecimal byte value; for example, 07h translates to 00000111, and the 1 bits in positions 3, 2, and 1 indicate the file is system, hidden, and read-only.

Table 24.8 FAT Directory File Attribute Byte

Bit Positions 7 6 5 4 3 2 1 0	Hex Value	Description
0 0 0 0 0 0 0 1	01h	Read-only file
0 0 0 0 0 0 1 0	02h	Hidden file
0 0 0 0 0 1 0 0	04h	System file
0 0 0 0 1 0 0 0	08h	Volume label
0 0 0 1 0 0 0 0	10h	Subdirectory
0 0 1 0 0 0 0 0	20h	Archive (updated since backup)
0 1 0 0 0 0 0 0	40h	Reserved
1 0 0 0 0 0 0 0	80h	Reserved
		Examples
0 0 0 0 0 1 1 1	07h	System, hidden, read-only
0 0 1 0 0 0 0 1	21h	Read-only, archive
0 0 1 1 0 0 1 0	32h	Hidden, subdirectory, archive
0 0 1 0 0 1 1 1	27h	Read-only, hidden, system, archive

File Allocation Tables

The file allocation table (FAT) is a list of numerical entries describing how each cluster in the partition is allocated. The data area of the partition has a single entry in the table for each of its clusters. Sectors in the non-data area of the partition are outside the range of the disk controlled by the FAT. Thus, the sectors that comprise the boot records, FATs, and root directory are outside the range of sectors controlled by the FAT.

▶▶ See "The Data Area," p. 1355.

The FAT does not manage every data sector specifically, but rather allocates space in groups of sectors called *clusters* or *allocation units*. A cluster is a unit of storage consisting of one or more sectors. The FDISK program determines the size of a cluster during the creation of the partition, based on the partition's size. The smallest space a file can occupy in a partition is one cluster; all files use space in integer (whole) cluster units. If a file is one byte larger than one cluster, two whole clusters are used.

You can think of the FAT as a type of spreadsheet that tracks the allocation of the disk's clusters. Each cell in the spreadsheet corresponds to a single cluster on the disk. The number stored in that cell is a code indicating whether a file uses the cluster and, if so, where the next cluster of the file is located. Thus, to determine which clusters a particular file is using, you would start by looking at the first FAT reference in the file's directory entry. When you look up the referenced cluster in the FAT, the table contains a reference to the file's next cluster. Each FAT reference, therefore, points to the next cluster in what is called a FAT *chain* until you reach the cluster containing the end of the file. Numbers stored in the FAT are hexadecimal numbers that are either 12 or 16 bits long. The 16-bit FAT numbers are easy to follow in a disk sector editor because they take an even 2 bytes of space. The 12-bit numbers are 1 1/2 bytes long, which presents a problem because most disk sector editors show data in byte

units. To edit a 12-bit FAT, you must do some hex/binary math to convert the displayed byte units to FAT numbers. Fortunately (unless you are using the DOS `DEBUG` program), most of the available tools and utility programs have a FAT-editing mode that automatically converts the numbers for you. Most of them also show the FAT numbers in decimal form, which most people find easier to handle. Table 24.9 shows the relationship between the directory and FAT for a given file (assuming the file is not fragmented).

Table 24.9 Directory and FAT Relationship (File Not Fragmented)

Directory		
Name	**Starting Cluster**	**Size**
`USCONST.TXT`	1000	4
FAT16 File Allocation Table		
FAT Cluster #	**Value**	**Meaning**
00002	0	First cluster available
…	…	…
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1002	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of file
01004	0	Cluster available
01005	0	Cluster available
…	…	…
65526	0	Last cluster available

In this example, the directory entry states that the file starts in cluster number 1000. In the FAT, that cluster has a nonzero value, which indicates it is in use; the specific value indicates where the file using it would continue. In this case, the entry for cluster 1000 is 1001, which means the file continues in cluster 1001. The entry in 1001 points to 1002, and from 1002 the entry points to 1003. The entry for 1003 is FFFFh, which is an indication that the cluster is in use but that the file ends here and uses no additional clusters.

The use of the FAT becomes clearer when you see that files can be fragmented. Let's say that before the `USCONST.TXT` file was written, another file already occupied clusters 1002 and 1003. If `USCONST.TXT` was written starting at 1000, it would not have been capable of being completely written before running into the other file. As such, the operating system would skip over the used clusters and continue the file in the next available cluster. The end result is shown in Table 24.10.

Table 24.10 Directory and FAT Relationship (Fragmented File)

Directory		
Name	**Starting Cluster**	**Size**
`PLEDGE.TXT`	1002	2
`USCONST.TXT`	1000	4

Table 24.10 Continued

FAT16 File Allocation Table

FAT Cluster #	Value	Meaning
00002	0	First cluster available
…	…	…
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1004	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of file
01004	1005	In use, points to next cluster
01005	FFFFh	End of file
…	…	…
65526	0	Last cluster available

In this example, the `PLEDGE.TXT` file that was previously written interrupted `USCONST.TXT`, so those clusters are skipped over, and the pointers in the FAT reflect that. Note that the defrag programs included with DOS and Windows take an example like this and move the files so they are contiguous, one after the other, and update the FAT to indicate the change in cluster use.

The first two entries in the FAT are reserved and contain information about the table itself. All remaining entries correspond to specific clusters on the disk. Most FAT entries consist of a reference to another cluster containing the next part of a particular file. However, some FAT entries contain hexadecimal values with special meanings, as follows:

- *0000h.* Indicates that the cluster is not in use by a file
- *FFF7h.* Indicates that at least one sector in the cluster is damaged and that it should not be used to store data
- *FFF8h–FFFFh.* Indicates that the cluster contains the end of a file and that no reference to another cluster is necessary

The FDISK program determines whether a 12-bit, 16-bit, or 32-bit FAT is placed on a disk, even though the FAT isn't written until you perform a high-level format (using the `FORMAT` utility). On today's systems, usually only floppy disks use 12-bit FATs, but FDISK also creates a 12-bit FAT if you create a hard disk volume that is smaller than 16MB (32,756 sectors). On hard disk volumes of more than 16MB, FDISK creates a 16-bit FAT. On drives larger than 512MB, the FDISK program included in Windows 95 OSR2, Windows 98, and Windows Me enables you to create 32-bit FATs when you answer Yes to the question `Enable Large Disk Support?` when you start FDISK. You can also select FAT32 when you prepare a drive with the Windows 2000 or Windows XP Disk Administrator program.

FDISK creates two copies of the FAT. Each one occupies contiguous sectors on the disk, and the second FAT copy immediately follows the first. Unfortunately, the operating system uses the second FAT copy only if sectors in the first FAT copy become unreadable. If the first FAT copy is corrupted, which is a much more common problem, the operating system does not use the second FAT copy. Even the `CHKDSK` command does not check or verify the second FAT copy. Moreover, whenever the OS updates the first FAT, it automatically copies large portions of the first FAT to the second FAT. If the first copy

was corrupted and subsequently updated by the OS, a large portion of the first FAT is copied over to the second FAT copy, damaging it in the process. After the update, the second copy is usually a mirror image of the first one, complete with any corruption. Two FATs rarely stay out of sync for very long. When they are out of sync and the OS writes to the disk, it updates the first FAT and overwrites the second FAT with the first. This is why disk repair and recovery utilities warn you to stop working as soon as you detect a FAT problem. Programs such as Norton Disk Doctor use the second copy of the FAT as a reference to repair the first one, but if the OS has already updated the second FAT, repair might be impossible.

Clusters (Allocation Units)

The term *cluster* was changed to *allocation unit* in DOS 4.0 (although many people continue to use the old term). *Allocation unit* is appropriate because a single cluster is the smallest unit of the disk that the operating system can handle when it writes or reads a file. A cluster is equal to one or more 512-byte sectors, in a power of 2. Although a cluster can be a single disk sector, it is usually more than one. Having more than one sector per cluster reduces the size and processing overhead of the FAT and enables the operating system to run faster because it has fewer individual units to manage. The trade-off is in wasted disk space. Because operating systems manage space only in full-cluster units, every file consumes space on the disk in increments of one cluster.

Table 24.11 shows the default cluster (or allocation unit) sizes for the various floppy disk formats used over the years.

Table 24.11 Default Floppy Disk Cluster (Allocation Unit) Sizes

Drive Type	Cluster (Allocation Unit) Size	Density
5 1/4" 360KB	2 sectors (1,024 bytes)	Low
5 1/4" 1.2MB	1 sector (512 bytes)	High
3 1/2" 720KB	2 sectors (1,024 bytes)	Low
3 1/2" 1.44MB	1 sector (512 bytes)	High
3 1/2" 2.88MB	2 sectors (1,024 bytes)	Extra

It seems strange that the high-density disks, which have many more individual sectors than low-density disks, sometimes have smaller cluster sizes. The larger the FAT, the more entries the operating system must manage and the slower it seems to function. This sluggishness is due to the excessive overhead required to manage all the individual clusters; the more clusters to be managed, the slower things become. The trade-off is in the minimum cluster size. High-density floppy disk drives are faster than their low-density counterparts, so perhaps IBM and Microsoft determined that the decrease in cluster size balances the drive's faster operation and offsets the use of a larger FAT.

Because the operating system can allocate only whole clusters, inevitably a certain amount of wasted storage space results. File sizes rarely fall on cluster boundaries, so the last cluster allocated to a particular file is rarely filled completely. The extra space left over between the actual end of the file and the end of the cluster is called *slack*. A partition with large clusters has more slack space, whereas smaller clusters generate less slack.

For hard disks, the cluster size varies greatly among partition sizes and file systems. With FAT16, the field in the disk parameter block that specifies the cluster size is 2 bytes long, so its maximum possible value is 65,535. Thus, the largest possible cluster is 32KB because a 64KB cluster would require a value of 65,536 in this field. Table 24.12 shows the cluster sizes FDISK selects for a particular volume size when FAT16 is the file system used.

Table 24.12 Default Hard Disk Cluster (Allocation Unit) Sizes for FAT16

Hard Disk Volume Size	Cluster (Allocation Unit) Size	FAT Type
0MB to less than 16MB	8 sectors or 4,096 bytes	12-bit
16MB–128MB	4 sectors or 2,048 bytes	16-bit
More than 128MB–256MB	8 sectors or 4,096 bytes	16-bit
More than 256BMB–512MB	16 sectors or 8,192 bytes	16-bit
More than 512MB–1,024MB	32 sectors or 16,384 bytes	16-bit
More than 1,024MB–2,048MB	64 sectors or 32,768 bytes	16-bit

The effect of larger cluster sizes on disk utilization can be substantial. A 2GB partition containing about 5,000 files, with average slack of one-half of the last 32KB cluster used for each file, wastes more than 78MB [5000×(.5×32)KB] of file space. When files under 32KB in size are stored on a drive with a 32KB allocation unit, waste (slack) factors can approach 40% of the drive's capacity.

The cluster size, in combination with the structure of the FAT, also dictates the maximum possible FAT partition size. Because the FAT uses 16-byte entries to reference the clusters in the partition, there can be a maximum of only 65,536 (2^{16}) clusters. At 32KB per cluster, the largest possible FAT16 partition is 2,096,832KB or 2,047.6875MB in size with MS-DOS and Windows 9x/Me. Even if the 2-byte cluster size field could contain the value indicating 64KB clusters, the maximum partition size would still be constrained. The maximum partition size would be limited by the field in the disk parameter block that specifies the number of sectors per cluster. This field is only 1 byte long, and its value must be a power of 2. This makes its highest possible value 128 sectors, which equates to a maximum cluster size of 64KB. 65,536 clusters at 64KB each equals a maximum partition size of 4GB.

Note

Windows NT/2000/XP support the use of 64KB clusters on FAT16 partitions, enabling you to create partitions up to 4GB in size. However, the huge amount of slack that generally results from clusters this large makes this practice undesirable. Also note that no other operating systems with FAT16 support are capable of accessing a FAT16 partition larger than 2GB.

The Data Area

The data area of a partition is the place where the actual files are stored. It is located following the boot record, file allocation tables, and root directory. This is the area of the disk that is divided into clusters and managed by the FAT and root directory.

Diagnostic Read-and-Write Cylinder

The FDISK partitioning program always reserves the last cylinder of a hard disk for use as a special diagnostic read-and-write test cylinder. Because this cylinder is reserved, FDISK always reports fewer total cylinders than the drive manufacturer states are available. Operating systems do not use this cylinder for any normal purpose because it lies outside the partitioned area of the disk.

◀◀ See "Disk Formatting," p. 604.

On systems with IDE or SCSI disk interfaces, the drive and controller also might allocate an additional area past the logical end of the drive for a bad-track table and spare sectors. This situation can account for additional discrepancies between the FDISK and the drive manufacturer's reported sizes.

The diagnostics area enables software such as a manufacturer-supplied diagnostics disk to perform read-and-write tests on a hard disk without corrupting any user data. Many of these programs also swap spare cylinders for damaged cylinders if damaged cylinders are detected during testing.

VFAT and Long Filenames

The original Windows 95 release uses what is essentially the same FAT file system as DOS, except for a few important enhancements. Like much of the rest of Windows 95, the operating system support for the FAT file system was rewritten using 32-bit code and called *VFAT (virtual file allocation table)*. VFAT works in combination with the 32-bit protected mode VCACHE (which replaces the 16-bit real mode SMARTDrive cache used in DOS and Windows 3.1) to provide better file system performance. However, the most obvious improvement in VFAT is its support for long filenames. DOS and Windows 3.1 had been encumbered by the standard 8.3 filenaming convention for many years, and adding long filename support was a high priority in Windows 95—particularly in light of the fact that Macintosh and OS/2 users had long enjoyed this capability.

The problem for the Windows 95 designers, as is often the case in the PC industry, was backward-compatibility. It is no great feat to make long filenames possible when you are designing a new file system from scratch, as Microsoft did years before with Windows NT's NTFS. However, the Windows 95 developers wanted to add long filenames to the existing FAT file system and still make it possible to store those names on existing DOS volumes and for previous versions of DOS and Windows to access the files.

VFAT provides the capability to assign file and directory names that are up to 255 characters in length (including the length of the path). The three-character extension is maintained because, like previous Windows versions, Windows 9x relies on the extensions to associate file types with specific applications. VFAT's long filenames can also include spaces, as well as the following characters, which standard DOS 8.3 names can't: +,;=[].

The first problem when implementing the long filenames was how to make them usable to previous versions of DOS and 16-bit Windows applications that support only 8.3 names. The resolution to this problem was to give each file two names: a long filename and an alias that uses the traditional 8.3 naming convention. When you create a file with a long filename in Windows 9x, VFAT uses the following process to create an equivalent 8.3 alias name:

1. The first three characters after the last dot in the long filename become the extension of the alias.
2. The first six characters of the long filename (excluding spaces, which are ignored) are converted into uppercase and become the first six characters of the alias filename. If any of these six characters are illegal under the standard 8.3 naming rules (that is, +,;=[]), VFAT converts those characters into underscores.
3. VFAT adds the two characters ~1 as the seventh and eighth characters of the alias filename, unless this will result in a name conflict, in which case it uses ~2, ~3, and so on, as necessary.

Aliasing in Windows NT/2000/XP

Note that Windows NT/2000/XP creates aliases differently than Windows 9x (as shown later).

NT/2000/XP begins by taking the first six legal characters in the LFN and following them with a tilde and number. If the first six characters are unique, a number 1 follows the tilde.

If the first six characters aren't unique, a number 2 is added. NT/2000/XP uses the first three legal characters following the last period in the LFN for a file extension.

At the fifth iteration of this process, NT/2000/XP takes only the first two legal characters, performs a hash on the filename to produce four hexadecimal characters, places the four hex characters after the first two legal characters, and appends a ~5. The ~5 remains for all subsequent aliases; only the hex numbers change.

Tip

You can modify the behavior of the VFAT filename truncation mechanism to make it use the first eight characters of the long filename instead of the first six characters plus ~1. To do this, you must add a new binary value to the `HKEY_LOCAL_MACHINE\System\CurrentControlSet\control\FileSystem` Registry key called `NameNumericTail`, with a value of `0`. Changing the value to `1` returns the truncation process to its original state.

Although this Registry change creates "friendly" alias names, it causes many programs working with alias names to fail and is not recommended.

VFAT stores this alias filename in the standard name field of the file's directory entry. Any version of DOS or 16-bit Windows can therefore access the file using the alias name. The big problem that still remains, however, is where to store the long filenames. Clearly, storing a 255-character filename in a 32-byte directory entry is impossible (because each character requires 1 byte). However, modifying the structure of the directory entry would make the files unusable by previous DOS versions.

The developers of VFAT resolved this problem by using additional directory entries to store the long filenames. Each of the directory entries is still 32 bytes long, so up to 8 might be required for each long name, depending on its length. To ensure that these additional directory entries are not misinterpreted by earlier DOS versions, VFAT flags them with a combination of attributes that is not possible for a normal file: read-only, hidden, system, and volume label. These attributes cause DOS to ignore the long filename entries, while preventing them from being mistakenly overwritten.

Caution

When using long filenames on a standard FAT12 or FAT16 partition, you should avoid storing them in the root directory. Files with long names that take up multiple directory entries can more easily use up the limited number of entries allotted to the root directory than files with 8.3 names. On FAT32 drives, this is not a problem because the root directory has an unlimited number of entries.

In an experiment, I created a small (1KB) text file on a floppy disk and gave it a 135-character long filename using Windows 98. I copied the file and pasted it repeatedly into the root directory of a floppy disk using Windows Explorer. Before I could make 20 copies of the file, the system displayed a `File copying` error. The disk could not accept any more files because the extremely long filename had used up all the root directory entries.

This solution for implementing backward-compatible long filenames in Windows 9x is ingenious, but it is not without its problems. Most of these problems stem from the use of applications that can access only the 8.3 alias names assigned to files. In some cases, if you open a file with a long name using one of these programs and save it again, the connection to the additional directory entries containing the long name is severed and the long name is lost.

This is especially true for older versions of disk utilities, such as Norton Disk Doctor for MS-DOS, that are not designed to support VFAT. Most older applications ignore the additional directory entries because of the combination of attributes assigned to them, but disk repair utilities usually are designed to detect and "correct" discrepancies of this type. The result is that running an old version

of Norton Disk Doctor on a partition with long filenames results in the loss of all the long names. In the same way, backup utilities not designed for use with VFAT can strip off the long filenames from a partition.

Note

When using VFAT's long filename capabilities, you definitely should use disk and backup utilities that are intended to support VFAT. Windows 9x includes VFAT-compatible disk repair, defragmentation, and backup programs. If, however, you are for some reason inclined to use an older program that does not support VFAT, Windows 9x includes a clumsy, but effective, solution.

A program is included on the Windows 9x CD-ROM called LFNBK.EXE. It doesn't install with the operating system, but you can use it to strip the long filenames from a VFAT volume and store them in a text file called `LFNBK.DAT`. You can then work with the files on the volume as though they were standard 8.3 FAT files. Afterward, you can use LFNBK.EXE to restore the long filenames to their original places (assuming the file and directory structure has not changed). This is not a convenient solution, nor is it recommended for use in anything but extraordinary circumstances, but the capability is there if needed. Some backup programs designed for disaster recovery (which enable you to reconstruct the contents of the hard drive without reloading Windows first) have used this feature to enable restoration of a Windows drive with long filenames from a DOS prompt (where only 8.3 alias names usually are supported).

Another problem with VFAT's long filenames involves the process by which the file system creates the 8.3 alias names. VFAT creates a new alias every time you create or copy a file into a new directory; therefore, the alias can change. For example, you might have a file called `Expenses-January98.doc` stored in a directory with the alias `EXPENS~1.DOC`. If you use Windows 9x Explorer to copy this file to a directory that already contains a file called `Expenses-December97.doc`, you are likely to find that this existing file is already using the alias `EXPENS~1.DOC`. In this case, VFAT assigns `EXPENS~2.DOC` as the alias of the newly copied file, with no warning to the user. This is not a problem for applications that support VFAT because the long filenames are unchanged, but a user running an older application might open the `EXPENS~1.DOC` file expecting to find the list of January 1998 expenses and see the December 1997 expenses list instead.

FAT32

When the FAT file system was being developed, 2GB hard disk drives were a fantasy and no one expected the partition size limitation imposed by the combination of 16-bit FAT entries and 32KB cluster sizes to be a problem. Today, however, even low-end PCs come equipped with hard drives holding at least 10GB, and 20GB and 30GB drives are common. When you use the standard FAT file system with these larger drives, you must create several partitions, each no larger than approximately 2GB. To many users, having multiple drive letters representing a single disk is confusing, making organizing and locating files difficult.

To address this problem, Microsoft released an enhanced version of the FAT file system, called FAT32. FAT32 works just like the standard FAT; the only difference is that it uses numbers with more digits, so it can manage more clusters on a disk. Unlike VFAT, which is a Windows 9x innovation that uses existing file system structures, FAT32 is an enhancement of the FAT file system itself. In other words, whereas VFAT is implemented as part of the Windows 9x Virtual Machine Manager (Vmm.vxd), FAT32 is implemented by the FDISK program before the Windows GUI is even loaded. FAT32 was first included in the Windows 95 OEM Service Release 2 (OSR2) and is also part of Windows 98/Me, Windows 2000, and Windows XP operating systems.

Note

Because the FDISK utility can implement the FAT32 file system when you partition the drive, you can't use FAT32 on a floppy disk or any removable cartridge that does not use a partition table. However, any medium you can partition with FDISK, such as an Iomega Jaz cartridge, can use FAT32.

The most obvious improvement in FAT32 is that by using 32-bit values for FAT entries instead of 16-bit ones, the maximum number of clusters allowed in a single partition jumps from 65,536 (2^{16}) to 268,435,456. This value is equivalent to 2^{28}, not 2^{32}, because 4 bits out of the 32 are reserved for other uses. FAT32 also uses 32-bit values for the low-level operating system calls used to retrieve a specific disk sector.

These expanded values blow the top off the 2GB limit on partition sizes; FAT32 partitions can theoretically be up to 2TB in size (1TB = 1,024GB). This figure is derived from a new maximum of 4,294,967,296 (2^{32}) possible 512-byte sectors. Individual files can be up to 4GB in size and are limited by the size field in the directory entry, which is 4 bytes long. Because the clusters are numbered using 32-bit values instead of 16-bit ones, the format of the directory entries on a FAT32 partition must be changed slightly. The 2-byte Link to Start Cluster field is increased to 4 bytes, using 2 of the 10 bytes (bytes 12–21) in the directory entry that were reserved for future use. In reality, limitations in the design of Windows 9x and the current ATA-5 version of the IDE specification restrict maximum disk size to a still-impressive 128GB. Windows 2000 and Windows XP can format a FAT32 partition of 32GB or less but can read larger FAT32 partitions.

Another important difference in FAT32 partitions is the nature of the root directory. In a FAT32 partition, the root directory does not occupy a fixed position on the disk as in a FAT16 partition. Instead, it can be located anywhere in the partition and expand to any size. This eliminates the preset limit on root directory entries and provides the infrastructure necessary to make FAT32 partitions dynamically resizable. Microsoft has not yet implemented this feature in Windows 9x/Me, but third-party products such as PowerQuest's PartitionMagic take advantage of this capability.

The primary drawback of FAT32 is that it is not compatible with previous versions of DOS and Windows 95. You can't boot to a previous version of DOS or (pre-OSR2) Windows 95 from a FAT32 drive, nor can a system started with an old DOS or Windows 95 boot disk see FAT32 partitions. Apart from Windows 95 OSR2, Windows 98/Me, and Windows 2000/XP, the only operating system that natively supports FAT32 is Linux. Most recent distributions of Linux now support FAT32, but older ones might require a patch. Check your distribution's documentation for details.

FAT32 Cluster Sizes

Because FAT32 partitions can have so many more clusters than FAT16 partitions, the clusters themselves can be smaller. Using smaller clusters reduces the wasted disk space caused by slack. For example, the same 2GB partition with 5,000 files on it mentioned earlier would use 4KB clusters with FAT32 instead of 32KB clusters with FAT16. Assuming the same amount of slack for each file, the smaller cluster size reduces the average amount of wasted space on that partition from more than 78MB to less than 10MB.

To compare FAT16 and FAT32, you can look at how a file would be stored on each. For FAT16, I'll use the same example as before. With FAT16 the cluster numbers are stored as 16-bit entries, from 0000h to FFFFh. The largest value possible is FFFFh, which corresponds to 65,535 in decimal, but several numbers at the beginning and end are reserved for special use. The actual cluster numbers allowed in a FAT16 system range from 0002h to FFF6h, which is 2–65,526 in decimal. All files must be stored in cluster numbers within that range. That leaves only 65,524 valid clusters to use for storing files (cluster numbers below 2 and above 65,526 are reserved), meaning a partition must be broken up into that many clusters or less. A typical file entry under FAT16 might look like Table 24.13.

Table 24.13 FAT16 File Entries

Directory		
Name	**Starting Cluster**	**Size**
USCONST.TXT	1000	4
FAT16 File Allocation Table		
FAT Cluster #	**Value**	**Meaning**
00002	0	First cluster available
…	…	…
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1002	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of file
01004	0	Cluster available
…	…	…
65526	0	Last cluster available

With FAT32, the cluster numbers range from 00000000h to FFFFFFFFh, which is 0–4,294,967,295 in decimal. Again, some values at the low and high ends are reserved, and only values between 00000002h and FFFFFFF6h are valid, which means values 2–4,294,967,286 are valid. This leaves 4,294,967,284 valid entries, so the drive must be split into that many clusters or less. Because a drive can be split into so many more clusters, the clusters can be smaller, which conserves disk space. The same file as shown earlier could be stored on a FAT32 system as illustrated in Table 24.14.

Table 24.14 FAT32 File Entries

Directory		
Name	**Starting Cluster**	**Size**
USCONST.TXT	1000	8
FAT32 File Allocation Table		
FAT Cluster #	**Value**	**Meaning**
0000000002	0	First cluster available
…	…	…
0000000999	0	Cluster available
0000001000	1001	In use, points to next cluster
0000001001	1002	In use, points to next cluster
0000001002	1003	In use, points to next cluster
0000001003	1004	In use, points to next cluster
0000001004	1005	In use, points to next cluster
0000001005	1006	In use, points to next cluster
0000001006	1007	In use, points to next cluster

Table 24.14 Continued

FAT32 File Allocation Table		
FAT Cluster #	**Value**	**Meaning**
0000001007	FFFFFFFFh	End of file
0000001008	0	Cluster available
…	…	…
4,294,967,286	0	Last cluster available

Because the FAT32 system enables many more clusters to be allocated, the cluster size is usually smaller. So, although files overall use more individual clusters, less wasted space results because the last cluster is, on average, only half filled.

Note

PC Magazine has released a free DOS utility called CHKDRV that calculates the slack on a FAT16 or FAT32 partition. You can download this program from `ftp://ftp.zdnet.com/pcmag/1995/0627/chkdrv.zip`.

Table 24.15 lists the cluster sizes for various FAT32 partition sizes.

Table 24.15 FAT32 Cluster Sizes

32GB–2TB	32,768 bytes		
Maximum Volume Sectors	**Volume Size (MiB)**	**Cluster Size (Sectors)**	**Cluster Size (Bytes)**
66,600	32.5	FAT12/16	FAT12/16
532,480	260	1	512
16,777,216	8,192	8	4,096
33,554,432	16,384	16	8,192
67,108,864	32,768	32	16,384
4,294,967,296	2,097,152	64	32,768

MiB = Mebibytes (1,048,576 bytes)

Some additional limitations exist on FAT32 volumes. Volumes less than 512MB default to FAT16, but FAT32 partitions as small as 32.6MB can be forced using the proper utilities or commands. Anything smaller than that, however, must be either FAT16 or FAT12. Also Windows 2000/XP or later will not format a volume larger than 32GiB using FAT32. If you attempt to format a FAT32 partition larger than 32GiB under Windows 2000/XP or later, the format operation will fail near the end of the process and you might receive the following error message: `Logical Disk Manager: Volume size too big`. If you want to use a larger FAT32 partition under Windows 2000/XP or later, you can format the partition using Windows 9x/Me because Windows 2000/XP or later mounts and supports these larger FAT32 partitions without any other problems. The only additional limitation with FAT32 partitions under Windows 2000/XP or later is in the formatting process. Finally, remember that DOS, Windows 95a, and Windows NT (through 4.0) do not recognize FAT32 partitions and are incapable of booting from a FAT32 volume.

Using smaller clusters results in many more clusters and more entries in the FAT. A 2GB partition using FAT32 requires 524,288 FAT entries, whereas the same drive needs only 65,536 entries using FAT16. Thus, the size of one copy of the FAT16 table is 128KB (65,536 entries×16 bits = 1,048,576 bits/8 = 131,072 bytes/1,024 = 128KB), whereas the FAT32 table is 2MB in size.

The size of the FAT has a definite impact on the performance of the file system. Windows 9x/Me uses VCACHE to keep the FAT in memory at all times to improve file system performance. The use of 4KB clusters for drives up to 8GB in size is, therefore, a reasonable compromise for the average PC's memory capacity. If the file system were to use clusters equal to one disk sector (1 sector = 512KB) in an attempt to minimize slack as much as possible, the FAT table for a 2GB drive would contain 4,194,304 entries and be 16MB in size.

This would monopolize a substantial portion of the memory in the average system, probably resulting in noticeably degraded performance. Although at first it might seem as though even a 2MB FAT is quite large when compared to 128KB, keep in mind that hard disk drives are a great deal faster now than they were when the FAT file system was originally designed. In practice, FAT32 typically results in a minor (less than 5%) improvement in file system performance. However, systems that perform a great many sequential disk writes might see an equally minor degradation in performance.

FAT Mirroring

FAT32 also takes greater advantage of the two copies of the FAT stored on a disk partition. On a FAT16 partition, the first copy of the FAT is always the primary copy and replicates its data to the secondary FAT, sometimes corrupting it in the process. On a FAT32 partition, when the system detects a problem with the primary copy of the FAT, it can switch to the other copy, which then becomes the primary. The system can also disable the FAT mirroring process to prevent the viable FAT from being corrupted by the other copy. This provides a greater degree of fault tolerance to FAT32 partitions, often enabling you to repair a damaged FAT without an immediate system interruption or a loss of table data.

Creating FAT32 Partitions

Despite the substantial changes FAT32 provides, the new file system does have a large effect on the procedures you use to create and manage partitions. You create new FAT32 partitions in Windows 9x using the FDISK utility from the command prompt, just as you would create FAT16 partitions. When you launch FDISK, the program examines your hard disk drives and, if they have a capacity greater than 512MB, presents the following message:

```
Your computer has a disk larger than 512 MB. This version of Windows
includes improved support for large disks, resulting in more efficient
use of disk space on large drives, and allowing disks over 2 GB to be
formatted as a single drive.

IMPORTANT: If you enable large disk support and create any new drives on this
disk, you will not be able to access the new drive(s) using other operating
systems, including some versions of Windows 95 and Windows NT, as well as
earlier versions of Windows and MS-DOS. In addition, disk utilities that
were not designed explicitly for the FAT32 file system will not be able
to work with this disk. If you need to access this disk with other operating
systems or older disk utilities, do not enable large drive support.

Do you wish to enable large disk support (Y/N).....? [N]
```

If you answer Yes to this question, any partitions you create that are larger than 512MB will be FAT32 partitions. If you want to create partitions larger than 2GB, you must use FAT32. Otherwise, you can choose which file system you prefer. All the screens following this one are the same as those in previous versions of FDISK.

Normally, the FDISK utility determines the cluster size used when you format the partition, based on the partition's size and the file system used. However, you can override FDISK using an undocumented switch for the `FORMAT` utility. If you use the command

```
FORMAT /Z:n
```

where *n* multiplied by 512 equals the desired cluster size in bytes, you can create a partition that uses cluster sizes that are larger or smaller than the defaults for the file system.

Caution

The `/Z` switch does not override the 65,536-cluster limit on FAT16 partitions, so it is recommended that you use it only with FAT32. In addition, you should not use this switch on a production system without extensive testing first. Modifying the cluster size can increase or decrease the amount of slack on the partition, but it also can have a pronounced effect on the performance of the drive. Some disk utilities might not work with nonstandard cluster sizes.

Converting FAT16 to FAT32

If you want to convert an existing FAT16 partition to FAT32, Windows 98 and later include a FAT32 Conversion Wizard that enables you to migrate existing partitions in place.

The wizard gathers the information needed to perform the conversion, informs you of the consequences of implementing FAT32, and attempts to prevent data loss and other problems. After you have selected the drive you want to convert, the wizard performs a scan for applications (such as disk utilities) that might not function properly on the converted partition. The wizard gives you the opportunity to remove these and warns you to back up the data on the partition before proceeding with the conversion. Even if you don't use the Microsoft Backup utility the wizard offers, backing up your data is a strongly recommended precaution.

Because the conversion must deal with the existing partition data in addition to creating new volume boot record information, FATs, and clusters, the process can take far longer than partitioning and formatting an empty drive. Depending on the amount of data involved and the new cluster size, the conversion can take several hours to complete.

After you convert a FAT16 partition to FAT32, you can't convert it back with Windows tools, except by destroying the partition and using FDISK to create a new one. Aftermarket partitioning utilities are available that can convert FAT32 back to FAT16 if you want. You should take precautions before beginning the conversion process, such as connecting the system to a UPS. A power failure during the conversion could result in a loss of data.

Third-Party Partitioning Utilities

Windows includes only basic tools for creating FAT32 partitions, but programs such as Partition Commander from VCOM (`www.v-com.com`) and PartitionMagic from PowerQuest (`www.powerquest.com`) provide many other partition manipulation features. These programs can easily convert partitions back and forth between FAT16, FAT32, and NTFS file systems, as well as resize, move, and copy partitions without destroying the data they contain. They also allow changes in cluster sizes beyond what the standard Windows tools create.

FAT File System Errors

File system errors can, of course, occur because of hardware problems, but you are more likely to see them result from software crashes and improper system handling. Turning off a system without shutting down Windows properly, for example, can result in errors that cause clusters to be incorrectly

listed as in use when they are not. Some of the most common file system errors that occur on FAT partitions are described in the following sections.

Lost Clusters

Probably the most common file system error, *lost* clusters are clusters the FAT designates as being in use when they actually are not. Most often caused by an interruption of a file system process due to an application crash or a system shutdown, for example, the FAT entry of a lost cluster might contain a reference to a subsequent cluster. However, the FAT chain stemming from the directory entry has been broken somewhere along the line.

Lost clusters appear in the file structure as shown in Table 24.16.

Table 24.16 Lost Clusters in a File Structure

		Directory
Name	**Starting Cluster**	**Size**
(no entry)	0	0
	FAT16 File Allocation Table	
FAT Cluster #	**Value**	**Meaning**
00002	0	First cluster available
…	…	…
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1002	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of file
01004	0	Cluster available
…	…	…
65526	0	Last cluster available

The operating system sees a valid chain of clusters in the FAT but no corresponding directory entry to back it up. Programs that are terminated before they can close their open files typically cause this. The operating system usually modifies the FAT chain as the file is written, and the final step when closing is to create a matching directory entry. If the system is interrupted before the file is closed (such as by shutting down the system improperly), lost clusters are the result. Disk repair programs check for lost clusters by tracing the FAT chain for each file and subdirectory in the partition and building a facsimile of the FAT in memory. After compiling a list of all the FAT entries that indicate properly allocated clusters, the program compares this facsimile with the actual FAT. Any entries denoting allocated clusters in the real FAT that do not appear in the facsimile are lost clusters because they are not part of a valid FAT chain.

The utility typically gives you the opportunity to save the data in the lost clusters as a file before it changes the FAT entries to show them as unallocated clusters. If your system crashed or lost power while you were working with a word processor data file, for example, you might be able to retrieve text from the lost clusters in this way. When left unrepaired, lost clusters are unavailable for use by the system, reducing the storage capacity of your drive.

The typical choices you have for correcting lost clusters are to assign them a made-up name or zero out the FAT entries. If you assign them a name, you can at least look at the entries as a valid file and then delete the file if you find it useless. The CHKDSK and SCANDISK programs are designed to fix lost clusters by assigning them names starting with `FILE0001.CHK`. If more than one lost chain exists, sequential numbers following the first one are used. The lost clusters shown earlier could be corrected by CHKDSK or SCANDISK as shown in Table 24.17.

Table 24.17 Finding Lost Clusters

		Directory
Name	**Starting Cluster**	**Size**
`FILE0001.CHK`	1000	4
	FAT16 File Allocation Table	
FAT Cluster #	**Value**	**Meaning**
00002	0	First cluster available
…	…	…
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1002	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of file
01004	0	Cluster available
…	…	…
65526	0	Last cluster available

As you can see, a new entry was created to match the FAT entries. The name is made up because there is no way for the repair utility to know what the original name of the file might have been.

Cross-Linked Files

Cross-linked files occur when two directory entries improperly reference the same cluster in their Link to Start Cluster fields. The result is that each file uses the same FAT chain. Because the clusters can store data from only one file, working with one of the two files can inadvertently overwrite the other file's data.

Cross-linked files would appear in the file structure as shown in Table 24.18.

Table 24.18 Cross-Linked Files

		Directory
Name	**Starting Cluster**	**Size**
`USCONST.TXT`	1000	4
`PLEDGE.TXT`	1002	2

Table 24.18 Continued

FAT16 File Allocation Table		
FAT Cluster #	**Value**	**Meaning**
00002	0	First cluster available
…	…	…
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1002	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of file
01004	0	Cluster available
…	…	…
65526	0	Last cluster available

In this case, two files claim ownership of clusters 1002 and 1003, so these files are said to be cross-linked on 1002. When a situation such as this arises, one of the files typically is valid and the other is corrupt, being that only one actual given set of data can occupy a given cluster. The normal repair is to copy both files involved to new names, which duplicates their data separately in another area of the disk, and then delete *all* the cross-linked files. Deleting them all is important because by deleting only one of them, the FAT chain is zeroed, which further damages the other entries. Then, you can examine the files you copied to determine which one is good and which is corrupt.

Detecting cross-linked files is a relatively easy task for a disk repair utility because it must examine only the partition's directory entries and not the file clusters themselves. However, by the time the utility detects the error, the data from one of the two files is probably already lost—although you might be able to recover parts of it from lost clusters.

Invalid Files or Directories

Sometimes the information in a directory entry for a file or subdirectory can be corrupted to the point at which the entry is not just erroneous (as in cross-linked files) but invalid. The entry might have a cluster or date reference that is invalid, or it might violate the rules for the entry format in some other way. In most cases, disk repair software can correct these problems, permitting access to the file.

FAT Errors

As discussed earlier, accessing its duplicate copy can sometimes repair a corrupted FAT. Disk repair utilities typically rely on this technique to restore a damaged FAT to its original state, as long as the mirroring process has not corrupted the copy. FAT32 tables are more likely to be repairable because their more advanced mirroring capabilities make the copy less likely to be corrupted.

An example of a damaged FAT might appear to the operating system as shown in Table 24.19.

Table 24.19 Damaged FAT

Directory		
Name	**Starting Cluster**	**Size**
USCONST.TXT	1000	4
FAT16 File Allocation Table		
FAT Cluster #	**Value**	**Meaning**
00002	0	First cluster available
…	…	…
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	0	Cluster available
01002	1003	In use, points to next cluster
01003	FFFFh	End of file
01004	0	Cluster available
…	…	…
65526	0	Last cluster available

This single error would cause multiple problems to appear. The file USCONST.TXT would now come up as having an allocation error—in which the size in the directory no longer matches the number of clusters in the FAT chain. The file would end after cluster 1001 in this example, and the rest of the data would be missing if you loaded this file for viewing. Also, two lost clusters would exist; that is, 1002 and 1003 appear to have no directory entry that owns them. When multiple problems such as these appear, a single incident of damage is often the cause. The repair in this case could involve copying the data from the backup FAT back to the primary FAT, but in most cases, the backup is similarly damaged. Normal utilities would truncate the file and create an entry for a second file out of the lost clusters. You would have to figure out yourself that they really belong together. This is where having knowledge in data recovery can help over using automated utilities that can't think for themselves.

FAT File System Utilities

The CHKDSK, RECOVER, and SCANDISK commands are the DOS damaged-disk recovery team. These commands are crude, and their actions sometimes are drastic, but at times they are all that is available or necessary. RECOVER is best known for its function as a data recovery program, and CHKDSK typically is used for inspection of the file structure. Many users are unaware that CHKDSK can implement repairs to a damaged file structure. DEBUG, a crude, manually controlled program, can help in the case of a disk disaster—if you know exactly what you are doing.

SCANDISK is a safer, more automated, more powerful replacement for CHKDSK and RECOVER. It should be used in their places if you are running Windows 95 or newer or DOS 6.

If you are using MS-DOS 5.0 or older, the only disk testing utilities supplied with your version of MS-DOS are CHKDSK and RECOVER. To learn more about how CHKDSK works, see *Upgrading and Repairing PCs, 11th Edition*, included in electronic form on the DVD packaged with this book.

The *RECOVER* Command

The DOS RECOVER command is designed to mark clusters as bad in the FAT when the clusters can't be read properly. When the system can't read a file because of a problem with a sector on the disk going bad, the RECOVER command can mark the FAT so another file does not use those clusters. When used improperly, this program is highly dangerous. The RECOVER utility has not been included in DOS since version 5 and is not supplied in Windows 9x because its functionality has been replaced by SCANDISK.

Caution

Be very careful when you use **RECOVER**. Used improperly, it can do severe damage to your files and the FAT. If you enter the **RECOVER** command without a filename for it to work on, the program assumes you want every file on the disk recovered and operates on every file and subdirectory on the disk. It converts all subdirectories to files, places all filenames in the root directory, and gives them new names (**FILE0000.REC**, **FILE0001.REC**, and so on). This process essentially wipes out the file system on the entire disk. Do not use **RECOVER** without providing a filename for it to work on. This program should be considered as dangerous as the **FORMAT** command. **RECOVER** is so notorious for this behavior that older versions of the Norton Utilities had a "recover from DOS RECOVER" option that could sometimes undo the damage caused by improper use of **RECOVER**.

SCANDISK

You should check your FAT partitions regularly for the problems discussed in this chapter and any other difficulties that might arise. By far an easier and more effective solution for disk diagnosis and repair than CHKDSK and RECOVER is the SCANDISK utility, included with DOS 6 and higher versions, as well as with Windows 9x/Me. This program is more thorough and comprehensive than CHKDSK or RECOVER and can perform the functions of both of them—and a great deal more.

Note

The equivalent of **SCANDISK** in Windows NT/2000 and Windows XP is called **CHKDSK**, but it is far more powerful than the old MS-DOS **CHKDSK** program. For more information on the old MS-DOS **CHKDSK** program, see *Upgrading and Repairing PCs, 12th Edition*, included in its entirety on the DVD accompanying this book.

SCANDISK is similar to a scaled-down version of third-party disk repair programs such as Norton Disk Doctor, and it can verify both file structure and disk sector integrity. If SCANDISK finds problems, it can repair directories and FATs. If the program finds bad sectors in the middle of a file, it marks the clusters (allocation units) containing the bad sectors as bad in the FAT and attempts to read the file data by rerouting around the defect.

Windows 9x includes both DOS and Windows versions of SCANDISK, which are named SCANDISK.EXE and SCANDSKW.EXE, respectively. Windows scans your drives at the beginning of the operating system installation process and automatically loads the DOS version of SCANDISK whenever you restart your system after turning it off without completing the proper shutdown procedure. You can also launch SCANDISK.EXE from a DOS prompt or from a batch file using the following syntax:

```
Scandisk x: [/a] [/n] [/p] [dblspace.nnn/drvspace.nnn]
x: - designator of the drive that you want to scan
/a - scans all local fixed hard disks
/n - noninteractive mode; requires no user input
/p - scans only, without correcting errors
/custom - runs Scandisk with the options configured in the
➥[CUSTOM] section of the Scandisk.ini file
```

```
dblspace.nnn or drvspace.nnn - scans a compressed volume file,
➥where nnn is replaced by the file extension (such as 001)
```

The SCANDISK.INI file, located in the C:\WINDOWS\COMMAND directory on a Windows system by default, contains extensive and well-documented parameters you can use to control the behavior of SCANDISK.EXE. Note that the options in the SCANDISK.INI file are applied only to the DOS version of the utility and have no effect on the Windows GUI version.

You also can run the GUI version of the utility by opening the Start menu and selecting Programs, Accessories, System Tools. Both versions scan and repair the FAT and the directory and file structures, repair problems with long filenames, and scan volumes that have been compressed with DriveSpace or DoubleSpace.

SCANDISK provides two basic testing options: Standard and Thorough. The difference between the two is that the Thorough option causes the program to scan the entire surface of the disk for errors in addition to the items just mentioned. You also can select whether to run the program interactively or let it automatically repair any errors it finds.

The DOS and Windows versions of SCANDISK also test the FAT in different ways. The DOS version scans and, if necessary, repairs the primary copy of the file allocation table. After this, it copies the repaired version of the primary to the backup copy. The Windows version, however, scans both copies of the FAT. If the program finds discrepancies between the two copies, it uses the data from the copy that it judges to be correct and reassembles the primary FAT using the best data from both copies. If the FAT information is not reconstructed correctly, some or all of your data might become inaccessible.

SCANDISK also has an Advanced Options dialog box that enables you to set the following parameters:

- Whether the program should display a summary of its findings
- Whether the program should log its findings
- How the program should repair cross-linked files (two directory entries pointing to the same cluster)
- How the program should repair lost file fragments
- Whether to check files for invalid names, dates, and times

Although SCANDISK is good, and is certainly a vast improvement over the old DOS CHKDSK, I recommend using one of the commercial packages, such as the Norton Utilities or Norton System Works, for any major disk problems. These utilities go far beyond what is included in DOS or Windows.

Disk Defragmentation

The entire premise of the FAT file systems is based on the storage of data in clusters that can be located anywhere on the disk. This enables the computer to store a file of nearly any size at any time. The process of following a FAT chain to locate all the clusters holding the data for a particular file can force the hard disk drive to access many locations on the disk. Because of the physical work involved in moving the disk drive heads, reading a file that is heavily fragmented in this way is slower than reading one that is stored on consecutive clusters.

As you regularly add, move, and delete files on a disk over a period of time, the files become increasingly fragmented, which can slow down disk performance. You can relieve this problem by periodically running a disk defragmentation utility on your drives, such as the one included with Windows 9x. When you run Disk Defragmenter, the program reads each of the files in the disk, using the FAT table to access its clusters, wherever they might be located.

The program then writes the file to a series of contiguous clusters and deletes the original. By progressively reading, erasing, and writing files, the program eventually leaves the disk in a state where all its files exist on contiguous clusters. As a result, the drive is capable of reading any file on the disk with a minimum of head movement, thus providing what is often a noticeable performance increase.

The Windows Defragmentation utility provides this basic defragmenting function. It also enables you to select whether you want to arrange the files on the disk to consolidate the empty clusters into one contiguous free space (which takes longer). The Windows 98/Me version adds a feature that examines the files on the disk and arranges them with the most frequently used program files grouped together at the front of the disk, which can make programs load more quickly.

To show how defragmenting works, see the example of a fragmented file shown in Table 24.20.

Table 24.20 Fragmented File

Directory		
Name	**Starting Cluster**	**Size**
PLEDGE.TXT	1002	2
USCONST.TXT	1000	4
FAT16 File Allocation Table		
FAT Cluster #	**Value**	**Meaning**
00002	0	First cluster available
…	…	…
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1004	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of file
01004	1005	In use, points to next cluster
01005	FFFFh	End of file
…	…	…
65526	0	Last cluster available

In the preceding example, the file USCONST.TXT is fragmented in two pieces. If you ran a defragmenting program, the files would be read off the disk and rewritten in a contiguous fashion. One possible outcome is shown in Table 24.21.

Table 24.21 Defragmented File

Directory		
Name	**Starting Cluster**	**Size**
PLEDGE.TXT	1004	2
USCONST.TXT	1000	4

Table 24.21 Continued

FAT16 File Allocation Table

FAT Cluster #	Value	Meaning
00002	0	First cluster available
…	…	…
00999	0	Cluster available
01000	1001	In use, points to next cluster
01001	1002	In use, points to next cluster
01002	1003	In use, points to next cluster
01003	FFFFh	End of file
01004	1005	In use, points to next cluster
01005	FFFFh	End of file
…	…	…
65526	0	Last cluster available

Although it doesn't look like much was changed, you can see that now both files are in one piece, stored one right after the other. Because defragmenting involves reading and rewriting a possibly large number of files on your drive, it can take a long time, especially if you have a large drive with a lot of fragmented files and not very much free working space on the drive.

Third-party defragmentation utilities, such as the Speed Disk program included in the Norton Utilities, provide additional features, such as the capability to select specific files that should be moved to the front of the disk. Speed Disk also can defragment the Windows swap file and files that are flagged with the system and hidden attributes, which Disk Defragmenter will not touch.

Caution

Although the disk-defragmentation utilities included with Windows and third-party products are usually quite safe, you should always be aware that defragmenting a disk is an inherently dangerous procedure. The program reads, erases, and rewrites every file on the disk and has the potential to cause damage to your data when interrupted improperly. Although I have never seen a problem result from the process, an unforeseen event—such as a power failure—during a defragmentation procedure can conceivably be disastrous. I strongly recommend that you always run a disk-repair utility, such as `SCANDISK`, on your drives before defragmenting them and have a current backup ready.

Windows NT 4.0 does not include a defragmentation utility, but Windows 2000 and Windows XP do include such a utility.

Third-Party Programs

When you get a `Sector not found` error reading drive C:, the best course of action is to use one of the third-party disk-repair utilities on the market, rather than DOS's `RECOVER` or even `SCANDISK`. The Norton Utilities by Symantec (also included in Norton System Works) stands as perhaps the premier data recovery package on the market today. This package is comprehensive and automatically repairs most types of disk problems.

Norton Utilities and Norton System Works

Programs such as Norton Disk Doctor can perform much more detailed repairs with a greater amount of safety. Disk Doctor preserves as much of the data in the file as possible and can mark the FAT so the bad sectors or clusters of the disk are not used again. These programs also save Undo information, enabling you to reverse any data recovery operation.

Disk Doctor is part of Symantec's Norton Utilities package, which includes a great many other useful tools. For example, Norton Utilities has an excellent sector editor that enables you to view and edit any part of a disk, including the master and volume boot records, FATs, and other areas that fall outside the disk's normal data area. Currently, no other program is as comprehensive or as capable of editing disks at the sector level. The disk editor included with Norton Utilities can give the professional PC troubleshooter or repairperson the ability to work directly with any sector on the disk, but this does require extensive knowledge of sector formats and disk structures. The documentation with the package is excellent and can be very helpful if you are learning data recovery on your own.

Note

Data recovery is a lucrative service that the more advanced technician can provide. People are willing to pay much more to get their data back than to replace a hard drive.

You also can create a rescue disk for restarting your system and testing the drive in case of emergencies, unerase accidentally deleted files (even if the Recycle Bin was bypassed), and unformat accidentally formatted drives.

Norton Utilities is now available in version 2002 as a standalone product or as a component in Norton System Works 2002 (for Windows 9x/Me/NT/2000/XP). System Works 2002 also includes Norton Anti-Virus and Norton CleanSweep uninstaller; the Professional version also includes Norton Ghost disk imaging, WinFax Basic, and Web Services. Some of the programs provided with Norton Utilities are designed to be run from the command line or from a DOS prompt, such as

- Norton Disk Doctor (`NDD.EXE`)
- Disk Editor (`DISKEDIT.EXE`)
- UnErase (`UNERASE.EXE`)
- UnFormat (`UNFORMAT.EXE`)
- Rescue Restore (`RESCUE.EXE`)

However, most Norton Utilities programs are designed to be run from within the Windows GUI.

You should not use older versions of Norton Utilities, such as version 8.0 (designed for Windows 3.1 and MS-DOS), with 32-bit versions of Windows because of the possibility of data loss due to a lack of support for long filenames and large drives.

SpinRite 5

The SpinRite 5 program from Gibson Research (`http://grc.com`) provides testing of both IDE and SCSI hard drives as well as removable-media drives of all sizes that have FAT-type file systems, including FAT32. During testing, SpinRite 5 statistically analyzes hard-to-read disk sectors to determine their original contents; it then moves the data to a properly working area of the disk. This process takes longer than with a program such as DiskDoctor, but for heavily damaged disks and drives for which no backup is available, this process can be more successful at recovering data. Another handy feature of SpinRite 5 is its capability to query your drive's partition table to determine the disk geometry

originally used to set up the disk. This enables you to access data on a disk even if the factory disk geometry values were not used to prepare the disk with FDISK and were not written down for future use.

The most important consideration when you purchase third-party disk utilities is to choose products that support your file system. For example, Norton Utilities supports both FAT (including FAT32) and NTFS files systems. On the other hand, SpinRite 5 supports all FAT file systems but not NTFS. Never use a disk utility not designed for your file system, and never use an out-of-date disk utility (designed for an earlier operating system) on your disk. In both cases, you could cause irreparable damage to the data on your drive.

New Technology File System

New Technology File System (NTFS) is the native file system of Windows NT, Windows 2000, and Windows XP. Windows 2000 and Windows XP use an enhanced version of NTFS called NTFS 5 or NTFS 2000; Windows NT 4.0 must have Service Pack 4 or above installed to be capable of accessing an NTFS 5/NTFS 2000 disk. Although NT/2000/XP support FAT partitions (and Windows 2000/XP even support FAT32), NTFS provides many advantages over FAT, including long filenames, support for larger files and partitions, extended attributes, and increased security. NTFS, like all of Windows NT, was newly designed from the ground up. Backward-compatibility with previous Microsoft operating systems was not a concern because the developers were intent on creating an entirely new 32-bit platform. As a result, no operating systems other than Windows NT and Windows 2000/XP, which are based on Windows NT, can read NTFS partitions.

This is an important consideration. All the other Windows operating systems are fundamentally based on DOS and give you the alternative of booting to a DOS prompt in special situations. Whether you have to run a special DOS utility to configure a piece of hardware or perform an emergency disk repair, the DOS option is always there.

Windows NT/2000/XP are not DOS based. You can open a window that provides a DOS-like command prompt in Windows NT/2000/XP, but this is actually a DOS emulation—not a true shell. You can't boot the system to a command prompt, avoiding the GUI, as you can with Windows 9x unless you install the Windows 2000 or Windows XP Recovery Console. As the name implies, the Recovery Console is designed for system repair and maintenance procedures, not for routine use. You can, of course, bypass NT/2000/XP entirely by starting the system with a DOS boot disk, but if you have NTFS partitions on your drives, you can't access them from the DOS prompt.

NTFS supports filenames of up to 255 characters, using spaces, multiple periods, and any other standard characters except the following: *?/\;<>|. Because NTFS file offsets are 64 bits long, files and partitions can be truly enormous—up to 16EB (exabytes) in size (1EB = 2^{64} bytes = 17,179,869,184TB)! To give you an idea of just how much data this is, it is estimated that all the words ever spoken by humans throughout history would occupy 5EB of storage.

Since Windows NT 3.51, NTFS has also supported compression on a file-by-file basis through each file's properties sheet. No third-party program, such as WinZip or PKZip, is needed to compress or decompress files stored on an NTFS drive.

NTFS Architecture

Although NTFS partitions are very different from FAT partitions internally, they do comply with the extra-partitional disk structures described earlier in this chapter. NTFS partitions are listed in the master partition table of a disk drive's master boot record, just like FAT partitions, and they have a volume boot record as well, although it is formatted somewhat differently.

When a volume is formatted with NTFS, system files are created in the root directory of the NTFS volume. These system files can be stored at any physical location on the NTFS volume. This means that damage to any specific location on the disk will probably not render the entire partition inaccessible.

Typically, 10 NTFS system files are created when you format an NTFS volume. Table 24.22 shows the names and descriptions for these files.

Table 24.22 NTFS System Files

Filename	Meaning	Description
`$mft`	Master file table (MFT)	Contains a record for every file on the NTFS volume in its `Data` attribute
`$mftmirr`	Master file table2 (MFT2)	Mirror of the MFT used for recoverability purposes
`$badclus`	Bad cluster file	Contains all the bad clusters on the volume
`$bitmap`	Cluster allocation bitmap	Contains the bitmap for the entire volume, showing which clusters are used
`$boot`	Boot file	Contains the volume's bootstrap if the volume is bootable
`$attrdef`	Attribute definitions table	Contains the definition of all system- and user-defined attributes on the volume
`$logfile`	Log file	Logs file transactions; used for recoverability purposes
`$quota`	Quota table	Table used to indicate disk quota usage for each user on a volume; used in NTFS 5
`$upcase`	Upcase table	Table used for converting uppercase and lowercase characters to the matching uppercase Unicode characters
`$volume`	Volume	Contains volume information, such as volume name and version

An NTFS partition is based on a structure called the master file table (MFT). The MFT concept expands on that of the FAT. Instead of using a table of cluster references, the MFT contains much more detailed information about the files and directories in the partition. In some cases, it even contains the files and directories themselves.

The first record in the MFT is called the *descriptor*, which contains information about the MFT itself. The volume boot record for an NTFS partition contains a reference that points to the location of this descriptor record. The second record in the MFT is a mirror copy of the descriptor, which provides fault tolerance, should the first copy be damaged.

The third record is the log file record. All NTFS transactions are logged to a file that can be used to restore data in the event of a disk problem. The bulk of the MFT consists of records for the files and directories stored on the partition. NTFS files take the form of objects that have both user- and system-defined attributes. Attributes on NTFS partitions are more comprehensive than the few simple flags used on FAT partitions. All the information on an NTFS file is stored as attributes of that file. In fact, even the file data itself is an attribute. Unlike FAT files, the attributes of NTFS files are part of the file itself; they are not listed separately in a directory entry. Directories exist as MFT records as well, but they consist mainly of indexes listing the files in the directory—they do not contain the size, date, time, and other information about the individual files.

Thus, an NTFS drive's MFT is much more than a cluster list, like a FAT; it is actually the primary data storage structure on the partition. If a file or directory is relatively small (less than approximately 1,500 bytes), the entire file or directory might even be stored in the MFT. For larger amounts of storage, the MFT record for a file or directory contains pointers to external clusters in the partition. These

external clusters are called *extents*. All the records in the MFT, including the descriptors and the log file, are capable of using extents for storage of additional attributes. The attributes of a file that are part of the MFT record are called *resident* attributes, whereas those stored in extents are called *nonresident* attributes.

NTFS 5 (NTFS 2000)

Along with Windows 2000 came a new variation of NTFS called NTFS 5 (also called NTFS 2000); NTFS 5 is also used by Windows XP. This update of the NT file system includes several new features that are exploited and even required by Windows 2000. Because of this, when you install Windows 2000, any existing NTFS volumes automatically are upgraded to NTFS 5 (there is no way to override). If you also run Windows NT versions earlier than Windows NT 4 Service Pack 4 (SP4), NT 4 is no longer capable of accessing the NTFS 5 volumes. If you want to run both NT 4 and Windows 2000 on the same system (as in a dual-boot configuration), you must upgrade NT 4 by installing Service Pack 4 or later. An updated `NTFS.SYS` driver in Service Pack 4 enables NT 4 to read from and write to NTFS 5 volumes.

New features of the NTFS 5 file system include

- *Disk quotas*. System administrators can limit the amount of disk space users can consume on a per-volume basis. The three quota levels are Off, Tracking, and Enforced.
- *Encryption*. NTFS 5 can automatically encrypt and decrypt files as they are read from and written to the disk.
- *Reparse points*. Programs can trap open operations against objects in the file system and run their own code before returning file data. This can be used to extend file system features such as mount points, which you can use to redirect data read and written from a folder to another volume or physical disk.
- *Sparse files*. This feature enables programs to create very large files as placeholders but to consume disk space by adding to the files only as necessary.
- *USN (Update Sequence Number) Journal*. Provides a log of all changes made to files on the volume.

Because these features—especially the USN Journal—are required for Windows 2000 to run, a Win2000 domain controller must use an NTFS 5 partition as the system volume.

NTFS Compatibility

Although NTFS partitions are not directly accessible by DOS and other operating systems, Windows NT/2000 is designed for network use, so other operating systems are expected to be capable of accessing NTFS files via the network. For this reason, NTFS continues to support the standard DOS file attributes and the 8.3 FAT naming convention.

One of the main reasons for using NTFS is the security it provides for its files and directories. NTFS security attributes are called *permissions* and are designed to enable system administrators to control access to files and directories by granting specific rights to users and groups. This is a much more granular approach than the FAT file system attributes, which apply to all users.

However, you can still set the FAT-style attributes on NTFS files using the standard Windows NT/2000 file management tools, including Windows NT/2000 Explorer and even the command-prompt `ATTRIB` command. When you copy FAT files to an NTFS drive over the network, the FAT-style attributes remain in place until you explicitly remove them. This can be an important consideration because the FAT-style attributes take precedence over the NTFS permissions. A file on an NTFS drive that is flagged with the FAT read-only attribute, for example, can't be deleted by a Windows NT/2000 user, even if that user has NTFS permissions that grant her full access.

To enable DOS and 16-bit Windows systems to access files on NTFS partitions over a network, the file system maintains an 8.3 alias name for every file and directory on the partition. The algorithm for deriving the alias from the long filename is the same as that used by Windows 95's VFAT. Windows NT/2000 also provides its FAT partitions with the same type of long filename support used by VFAT, allocating additional directory entries to store the long filenames as necessary.

Creating NTFS Drives

NTFS is for use on hard disk drives. You can't create an NTFS floppy disk (although you can format removable media, such as Iomega Zip and Jaz cartridges to use NTFS). Three basic ways to create an NTFS disk partition are as follows:

- Create a new NTFS volume out of unpartitioned disk space during the Windows NT/2000 installation process or after the installation with the Disk Administrator utility.
- Format an existing partition to NTFS (destroying its data in the process), using the Windows NT Format dialog box (accessible from Windows NT Explorer or Disk Administrator) or the `FORMAT` command (with the `/fs:ntfs` switch) from the command prompt.
- Convert an existing FAT partition to NTFS (preserving its data) during the Windows NT/2000 installation process or after the installation with the command-line `CONVERT` utility.

NTFS Tools

Because it uses a fundamentally different architecture, virtually none of the troubleshooting techniques outlined earlier in this chapter are applicable when dealing with NTFS partitions, nor can the disk utilities intended for use on FAT partitions address them. Windows NT has a rudimentary capability to check a disk for file system errors and bad sectors with its own version of `CHKDSK`, but a part from that, the operating system contains no other disk repair or defragmentation utilities. Windows 2000 and Windows XP include a command-line and GUI version of `CHKDSK` and also include a defragmenting tool that is run from the Windows Explorer GUI.

The NTFS file system, however, does have its own automatic disk repair capabilities. In addition to Windows NT/2000/XP's fault-tolerance features, such as disk mirroring (maintaining the same data on two separate drives) and disk striping with parity (splitting data across several drives with parity information for data reconstruction), the OS also uses a disk error recovery technique called *cluster remapping*.

With cluster remapping, when Windows (NT/2000/XP) detects a bad sector on an NTFS partition, it automatically remaps the data in that cluster to another cluster. If the drive is part of a fault-tolerant drive array, any lost data is reconstructed from the duplicate data on the other drives.

Despite these features, however, there is still a real need for disk repair and defragmentation utilities for Windows NT/2000/XP. They have been a long time in coming, but finally third-party utilities now are available that can repair and defragment NTFS drives. One I recommend is Norton Utilities 2001 by Symantec, which works with Windows 98, Windows Me, Windows NT 4.0, and Windows 2000. An updated version is necessary for Windows XP.

High Performance File System

The High Performance File System (HPFS) was first introduced in OS/2 version 1.2 and included many additional features over the existing FAT16 system available at the time. In many ways, HPFS was the predecessor to the NTFS that later debuted in Windows NT.

HPFS uses directory entries like FAT does, but these directory entries hold more information, including the modification, creation, and access date and times. Directory entries in HPFS also point to the

FNODE for the file, which can contain the file's actual data or pointers to the file's data. HPFS automatically sorts the list of filenames in the directory, and filenames can be up to 254 double-byte characters in length. An important feature of HPFS is its efficiency—the allocation unit or cluster size has been reduced to a single physical sector (512 bytes), which reduces disk space lost to slack at the end of files.

File fragmentation is minimal in HPFS because it tries to allocate as much of a file in contiguous sectors as possible. To further increase access speed, HPFS organizes a drive into a series of 8MB bands and, whenever possible, attempts to keep a file within one of these bands. Between each band is a 2KB allocation bitmap that keeps track of which sectors within a band are allocated.

HPFS also includes several unique structures, such as the Super Block and the Spare Block. The Super Block is located in logical sector 16 and contains a pointer to the FNODE of the root directory. The Spare Block is located in logical sector 17 and contains the Spare Directory Block as well as a table of hot fixes, which allows spare sectors to be assigned on-the-fly.

If a bad sector is found, the hot fixes table is used to point to an existing good sector in place of the bad sector. Hot fixing enables spare sectors to be assigned on-the-fly, transparent to any applications that are running. Hot fixing is supported only under OS/2; Windows NT does not support hot fixing in its implementation of HPFS.

HPFS is supported only by OS/2 and has limited support under Windows NT versions 3.1, 3.5, and 3.51. No other versions of Windows can access HPFS partitions. Because OS/2 was not popular on PCs and is now considered obsolete, you will rarely encounter HPFS out in the field. When Windows NT 4.0 debuted, Microsoft abandoned HPFS in favor of the NTFS file system it had established in Windows.

Common Drive Error Messages and Solutions

Several common error messages are associated with problems in the file system or drives. This section covers the common ones, listing their causes and possible solutions.

Some of the most common file system errors are as follows:

- `Missing Operating System`
- `NO ROM BASIC - SYSTEM HALTED`
- `Boot Error Press F1 to Retry`
- `Invalid Drive Specification`
- `Invalid Media Type`
- `Hard Disk Controller Failure`

These usually occur when booting the system or when trying to log in to or access a drive. The following sections describe each of these errors and offer possible solutions.

Missing Operating System

This error indicates problems in the master boot record or partition table entries. The partition table entries might be pointing to a sector that is not the actual beginning of a partition. This can also be caused by invalid BIOS settings, in some cases resulting from a dead or dying battery. In fact, in my experience, corrupt or improper BIOS settings—such as incorrect geometry (cylinder/head/sector) or LBA mode settings—are the leading cause of this problem. Another cause can be virus damage to the MBR. This error also can occur if no active partition is defined in the partition table.

The normal solution is to correct the invalid BIOS settings. The BIOS settings for drive parameters and LBA translation must be set to the same values as when the drive was partitioned and formatted to read the drive correctly. If the MBR is damaged or virus infected, you can try `FDISK/MBR` to repair it. Other types of damage require more sophisticated use of a disk editor utility or repartitioning and reformatting the drive to start over.

NO ROM BASIC - SYSTEM HALTED

This error is generated by the AMI BIOS when the boot sector or master boot record of the boot drive is damaged or missing. This error also can occur if the boot device has been improperly configured or is not configured at all in the BIOS. In this case, data in the partition might be valid and undamaged, but no bootable partition exists.

IBM systems in this situation used to drop into a built-in BIOS version of BASIC, but most non-IBM BIOS manufacturers did not license this code from Microsoft. So, instead of dropping into BASIC, they displayed this cryptic message. Because the most common cause of this type of error is a failure to set at least one partition as active (bootable), the typical solution is to run FDISK and set the primary partition as active. If this is not the problem, the solution is to repair the damaged MBR or correct the improper BIOS settings.

Other possible problems include corrupted or missing drive parameters in the BIOS Setup.

Boot Error Press F1 to Retry

This error is generated by the Phoenix BIOS when the hard disk is missing a master boot record or boot sector or when there is a problem accessing the boot drive. This has the same meaning as `NO ROM BASIC` does on an AMI BIOS. The most common cause of this message is having no partitions defined as active (bootable). See the section on `NO ROM BASIC` earlier in the chapter for more information.

Invalid Drive Specification

This error occurs when you attempt to log in to a drive that has not been partitioned or for which the partition table entry has been damaged or is incorrect. Use FDISK to partition the drive or to check out the existing partitions. If they are damaged, you probably should use a data recovery utility such as the Norton Utilities to correct the problem. Such correction might require manual editing of the partition table with the DISKEDIT program included with the Norton Utilities. Another solution is to repartition the drive from scratch, but this causes any existing data on the drive to be overwritten.

Invalid Media Type

This indicates the partition table is valid, but the volume boot sector, directory, or file allocation tables are corrupt, damaged, or not yet initialized. For example, this is the standard error you would receive if you tried to access a drive that had been partitioned but not yet formatted. The `FORMAT` command is what creates the volume boot record (VBR), file allocation tables, and directories on the disk.

The repair typically involves using a data recovery utility, such as the Norton Utilities Disk Doctor, or redoing the high-level format on the drive. Because high-level formatting does not actually destroy the data, one technique to recover is to high-level format (OS Format) the volume and then immediately unformat it using the unformat utility included with the Norton Utilities.

Hard Disk Controller Failure

This message indicates the hard disk controller has failed, the hard disk controller is not set up properly in the BIOS, or the controller can't communicate with the attached drives (such as with cable problems).

The solution is to check out the drive installation and ensure that the cables to the drive are properly installed, the drive is receiving power, it is spinning, and the BIOS Setup definitions are correct. If all these are correct, the drive, cable, or controller might be physically damaged. Replace them with known-good spares one at a time until the problem is solved.

General File System Troubleshooting for MS-DOS, Windows 9x, and Windows Me

Here are some general procedures to follow for troubleshooting drive access, file system, or boot problems:

1. Start the system using a Windows startup disk, or any bootable MS-DOS disk that contains `FDISK.EXE`, `FORMAT.COM`, `SYS.COM`, and `SCANDISK.EXE` (Windows 95B or later versions preferred).
2. If your system can't boot from the floppy, you might have more serious problems with your hardware. Check the floppy drive and the motherboard for proper installation and configuration. On some systems, the BIOS configuration doesn't list the floppy as a boot device or puts it after the hard disk. Reset the BIOS configuration to make the floppy disk the first boot device if necessary and restart your computer.
3. Run FDISK from the Windows startup disk. Select option 4 (Display partition information).
4. If the partitions are listed, make sure that the bootable partition (usually the primary partition) is defined as active (look for an uppercase *A* in the Status column).
5. If no partitions are listed and you do not want to recover any of the data existing on the drive now, use FDISK to create new partitions, and then use `FORMAT` to format the partitions. This overwrites any previously existing data on the drive.
6. If you want to recover the data on the drive and no partitions are being shown, you must use a data recovery program, such as the Norton Utilities by Symantec or Lost and Found by PowerQuest, to recover the data.
7. If all the partitions appear in `FDISK.EXE` and one is defined as active, run the `SYS` command as follows to restore the system files to the hard disk:

   ```
   SYS C:
   ```

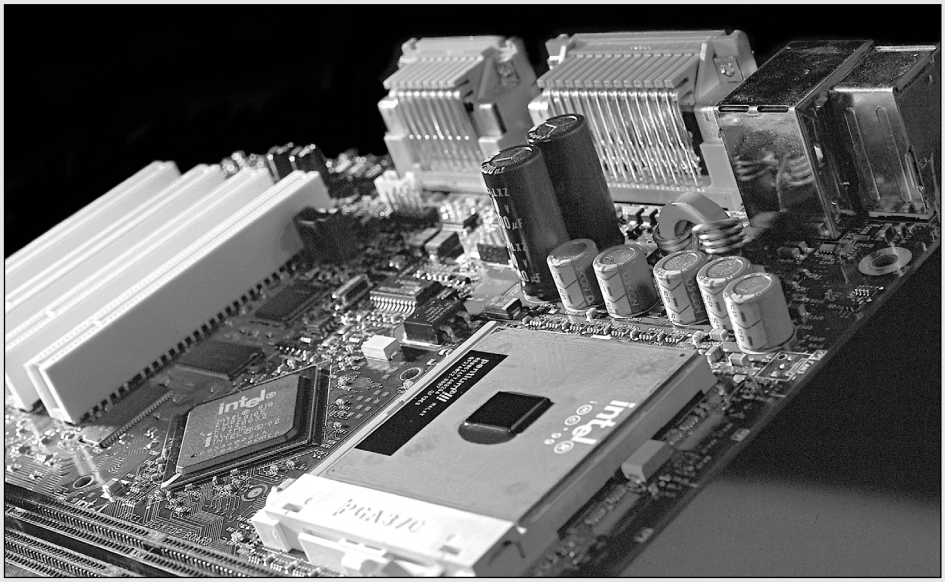
8. For this to work properly, it is important that the disk you boot from be a startup disk from the same operating system (or version of Windows) you have on your hard disk.
9. You should receive the message `System Transferred` if the command works properly. Remove the disk from drive A:, and restart the system. If you still have the same error as before after you restart your computer, your drive might be improperly configured or damaged.
10. Run `SCANDISK` from the Windows startup disk or an aftermarket data-recovery utility, such as the Norton Utilities, to check for problems with the hard disk.
11. Using `SCANDISK`, perform a surface scan. If `SCANDISK` reports any physically damaged sectors on the hard disk, the drive might need to be replaced.

General File System Troubleshooting for Windows 2000/XP

The process for file system troubleshooting with Windows 2000/XP is similar to that used for Windows 9x. The major difference is the use of the Windows 2000/XP Recovery Console, which is clarified here:

- If the Recovery Console was added to the boot menu, start the system normally, log in as Administrator if prompted, and select the Recovery Console.
- If the Recovery Console was not previously added to the boot menu, start the system using the Windows CD-ROM or the Windows Setup disks. Select Repair from the Welcome to Setup menu, and then press C to start the Recovery Console when prompted.

If your system can't boot from CD-ROM or the floppy, you might have more serious problems with your hardware. Check your drives, BIOS configuration, and motherboard for proper installation and configuration. Set the floppy disk as the first boot device and the CD-ROM as the second boot device and restart the system.



After you start the Recovery Console do the following:

1. Type **HELP** for a list of Recovery Console commands and assistance.
2. Run DISKPART to examine your disk partitions.
3. If the partitions are listed, make sure that the bootable partition (usually the primary partition) is defined as active.
4. If no partitions are listed and you do not want to recover any of the data existing on the drive now, use FDISK to create new partitions, and then use FORMAT to format the partitions. This overwrites any previously existing data on the drive.
5. If you want to recover the data on the drive and no partitions are being shown, you must use a data recovery program, such as the Norton Utilities by Symantec or Lost and Found by PowerQuest, to recover the data.
6. If all the partitions appear in DISKPART and one is defined as active, run the FIXBOOT command as follows to restore the system files to the hard disk:

   ```
   FIXBOOT
   ```

7. Type **EXIT** to restart your system. Remove the disk from drive A: or the Windows 2000 CD-ROM from the CD-ROM drive.
8. If you still have the same error as before after you restart your computer, your drive might be improperly configured or damaged.
9. Restart the Recovery Console and run CHKDSK to check for problems with the hard disk.

APPENDIX A

Glossary

This glossary contains computer and electronics terms that are applicable to the subject matter in this book. The glossary is meant to be as comprehensive as possible on the subject of upgrading and repairing PCs. Many terms correspond to the latest technology in disk interfaces, modems, video and display equipment, and standards that govern the PC industry. Although a glossary is a resource not designed to be read from beginning to end, you should find that scanning through this one is interesting, if not enlightening, with respect to some of the newer PC technology.

The computer industry is filled with abbreviations used as shorthand for a number of terms. This glossary defines many abbreviations, as well as the terms on which the abbreviations are based. The definition of an abbreviation usually is included under the acronym. For example, *video graphics array* is defined under the abbreviation *VGA* rather than under *video graphics array*. This organization makes looking up a term easier—*IDE*, for example—even if you do not know in advance what it stands for (*integrated drive electronics*).

For additional reference, *Que's Computer Dictionary* (ISBN: 0-7897-1670-4) is a comprehensive dictionary of computer terminology.

These Web sites can also help you with terms not included in this glossary:

```

http://www.webopedia.com

http://whatis.techtarget.com
```

1–50X CD-ROM maximum speeds in relation to the speed of a music CD (1X = 150KBps). At speeds of 16X or above, most drives are CAV and reach their rated speeds only on the outer edges of the disc. See also *CLV* and *CAV*.

10BASE-2 IEEE standard for baseband Ethernet at 10Mbps over RG-58 coaxial cable to a maximum distance of 185 meters. Also known as Thin Ethernet (Thinnet) or IEEE 802.3.

10BASE-5 IEEE standard for baseband Ethernet at 10Mbps over thick coaxial cable to a maximum distance of 500 meters. Also known as Thick Ethernet or Thicknet.

10BASE-T A 10Mbps CSMA/CD Ethernet LAN that works on Category 3 or better twisted-pair wiring, which is very similar to standard telephone cabling. 10BASE-T Ethernet LANs work on a "star" configuration, in which the wire from each workstation routes directly to a 10BASE-T hub. Hubs can be joined together. 10BASE-T has a maximum distance of 100 meters between each workstation and the hub.

24x7 Refers to continuous 24 hours a day, 7 days a week computer or services operation.

56K The generic term for modems that can receive data at 56Kbps. See also *V.90*, *V.92*, *X2*, *K56flex*.

64-bit processor A processor that has 64-bit registers. The Intel Itanium, which can also emulate 32-bit Intel processors, is one of several 64-bit processors now in use for enterprise server tasks.

100BASE-T A 100Mbps CSMA/CD Ethernet local area network (LAN) that works on Category 5 twisted-pair wiring. 100BASE-T Ethernet LANs work on a "star" configuration in which the wire from each workstation routes directly to a central 100BASE-T hub. This is the current standard for 100Mbps Ethernet, replacing 100BASE-VG.

100BASE-VG The joint Hewlett-Packard–AT&T proposal for Fast Ethernet running at 100Mbps. It uses four pairs of Category 5 cable using the 10BASE-T twisted-pair wiring scheme to transmit or receive. 100BASE-VG splits the signal across the four wire pairs at 25MHz each. This standard has not found favor with corporations and has been almost totally replaced by 100BASE-T.

286 See *80286*.

386 See *80386DX*.

404 Web site error code indicating the specified page is not found. Some Web sites display a customized error message instead of the standard 404 code.

486 See *80486DX*.

586 A generic term used to refer to fifth-generation processors similar to the Intel Pentium, such as the AMD K6 series and the VIA Cyrix MII.

640KB barrier The limit imposed by the PC-compatible memory model using DOS mode. DOS programs can address only 1MB total memory, and PC-compatibility generally requires the top 384KB to be reserved for the system, leaving only the lower 640KB for DOS or other real-mode applications.

802.11 The family name for various wireless Ethernet standards. See also *IEEE 802.11 Family*.

1000BASE-T A 1,000Mbps Ethernet local area network (LAN) that runs over four pairs of Category 5 cable. Popularly known as Gigabit Ethernet, 1000BASE-T can be used as an upgrade to a properly wired 100BASE-T network because the same cable and distance limitations (100 meters) apply.

1394 See *FireWire*.

8086 An Intel microprocessor with 16-bit registers, a 16-bit data bus, and a 20-bit address bus. This processor can operate only in real mode.

8087 An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 8087 can be installed in most 8086- and 8088-based systems and adds more than

50 new instructions to those available in the primary CPU alone.

8088 An Intel microprocessor with 16-bit registers, an 8-bit data bus, and a 20-bit address bus. This processor can operate only in real mode and was designed as a low-cost version of the 8086.

8514/A An analog video display adapter from IBM for the PS/2 line of personal computers. Compared to previous display adapters, such as EGA and VGA, it provides a high resolution of 1,024×768 pixels with as many as 256 colors or 64 shades of gray. It provides a video coprocessor that performs two-dimensional graphics functions internally, thus relieving the CPU of graphics tasks. It uses an interlaced monitor and scans every other line every time the screen is refreshed.

80286 An Intel microprocessor with 16-bit registers, a 16-bit data bus, and a 24-bit address bus. It can operate in both real and protected virtual modes.

80287 An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 80287 can be installed in most 286- and some 386DX-based systems, and it adds more than 50 new instructions to what is available in the primary CPU alone.

80386 See *80386DX*.

80386DX An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. This processor can operate in real, protected virtual, and virtual real modes.

80386SX An Intel microprocessor with 32-bit registers, a 16-bit data bus, and a 24-bit address bus. This processor, designed as a low-cost version of the 386DX, can operate in real, protected virtual, and virtual real modes.

80387DX An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 80387DX can be installed in most 386DX-based systems and adds more than 50 new instructions to those available in the primary CPU alone.

80387SX An Intel math coprocessor designed to perform floating-point math with much greater speed and precision than the main CPU. The 80387SX can be installed in most 386SX-based systems and adds more than 50 new instructions to those available in the primary CPU alone.

80486 See *80486DX*.

80486DX An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. The 486DX has a built-in cache controller with 8KB of cache memory as well as a built-in math coprocessor equivalent to a 387DX. The 486DX can operate in real, protected virtual, and virtual real modes.

80486DX2 A version of the 486DX with an internal clock-doubling circuit that causes the chip to run at twice the motherboard clock speed. If the motherboard clock is 33MHz, the DX2 chip will run at 66MHz. The DX2 designation applies to chips sold through the OEM market, whereas a retail version of the DX2 is sold as an overdrive processor.

80486DX4 A version of the 486DX with an internal clock-tripling circuit that causes the chip to run at three times the motherboard clock speed. If the motherboard clock is 33.33MHz, the DX4 chip will run at 100MHz.

80486SX An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. The 486SX is the same as the 486DX, except that it lacks the built-in math coprocessor function and was designed as a low-cost version of the 486DX. The 486SX can operate in real, protected virtual, and virtual real modes.

80487SX An Intel microprocessor with 32-bit registers, a 32-bit data bus, and a 32-bit address bus. Although the name implies that the 80487SX adds floating-point math capabilities, in reality the 487SX is the same as the 486DX, except that it uses a modified pinout and must be installed in a special 80487SX socket. When installed, the 80487SX replaces the 80486SX for all processing tasks. The 487SX can operate in real, protected virtual, and virtual real modes.

A+ Refers to the CompTIA A+ Certification, a vendor-neutral certification for computer hardware technicians. A+ Certification exams test knowledge of basic hardware and software skills. The A+ Certification can be used as part of the exam requirements for the Microsoft Certified System Administrator (MCSA) credential.

abend Short for *abnormal end*. A condition occurring when the execution of a program or task is terminated unexpectedly because of a bug or crash.

absolute address An explicit identification of a memory location, device, or location within a device.

AC (alternating current) The frequency is measured in cycles per seconds (cps) or hertz (Hz). The standard value running through the wall outlet is 120 volts at 60Hz through a fuse or circuit breaker that usually can handle about 15 or 20 amps.

accelerated graphics port See *AGP*.

Accelerated Hub Architecture (AHA) An Intel technology used on its 800-series chipsets to transfer data between the memory controller hub (MCH), which is equivalent to the North Bridge, and the input/output controller hub (ICH), which is equivalent to the South Bridge. AHA transfers data at 266MBps, twice the speed of the PCI bus previously used.

accelerator board An add-in board replacing the computer's CPU with circuitry that enables the system to run more quickly. See also *graphics accelerator*.

access light The LED on the front of a drive or other device (or on the front panel of the system) that indicates the computer is reading or writing data on the device.

access mechanism See *actuator*.

access time The time that elapses from the instant information is requested to the point that delivery is completed. It's usually described in nanoseconds (ns) for memory chips and in milliseconds (ms) for disk drives. Most manufacturers rate average access time on a hard disk as the time required for a seek across one third of the total number of cylinders plus one-half the time for a single revolution of the disk platters (latency).

accumulator A register (temporary storage) in which the result of an operation is formed.

acoustic coupler A device used to connect a computer modem to a phone line by connecting to the handset of a standard AT&T-style phone. The audible sounds to and from the modem are transmitted to the handset through the coupler while the handset is resting in the coupler. Although often thought of as obsolete, an acoustic coupler can be used to ensure the availability of a modem connection when traveling and access to an RJ-11 jack is unavailable.

ACPI (Advanced Configuration and Power Interface) A standard developed by Intel, Microsoft, and Toshiba that is designed to implement power management functions in the operating system. ACPI is a replacement for APM. See also *APM*.

ACR Short for Advanced Communication Riser, an alternative to CNR advocated by the ACR Special Interest Group (`www.acrsig.org`). ACR, like CNR, is designed to allow motherboard designers to add low-cost network capabilities to motherboards but uses the same PCI connector used by PCI expansion cards.

Acrobat Refers to the Adobe Acrobat program for creating and reading cross-platform documents created in Adobe's Portable Document Format (PDF) file format. Many computer and component manuals are available online in Acrobat format. The Acrobat Reader can be downloaded free from Adobe's Web site.

active high Designates a digital signal that must go to a high value to be true. Synonymous with positive.

active low Designates a digital signal that must go to a low value to be true. Synonymous with negative.

active matrix A type of LCD screen that contains at least one transistor for every pixel on the screen. Color active-matrix screens use

three transistors for each pixel—one each for the red, green, and blue dots. The transistors are arranged on a grid of conductive material, with each connected to a horizontal and a vertical member. See also *TFT*.

active partition Any partition marked as bootable in the partition table.

actuator The device that moves a disk drive's read/write heads across the platter surfaces. Also known as an access mechanism.

adapter The device that serves as an interface between the system unit and the devices attached to it. It's often synonymous with circuit board, circuit card, or card, but it also can refer to a connector or cable adapter that changes one type of connector to another.

adapter description files (ADF) Refers to the setup and configuration files and drivers necessary to install an adapter card, such as a network adapter card. Primarily used with Micro Channel Architecture (MCA) bus cards.

add-in board See *expansion card*.

address Refers to where a particular piece of data or other information is found in the computer. Also can refer to the location of a set of instructions.

address bus One or more electrical conductors used to carry the binary-coded address from the microprocessor throughout the rest of the system.

ADSL (asymmetric digital subscriber line) A high-speed transmission technology originally developed by Bellcore and now standardized by ANSI as T1.413. ADSL uses existing UTP copper wires to communicate digitally at high speed between the telephone company central office (CO) and the subscriber. ADSL sends information asymmetrically, meaning it is faster one way than the other. The original ADSL speed was T-1 (1.536Mbps) downstream from the carrier to the subscriber's premises and 16Kbps upstream. However, ADSL is available in a variety of configurations and speeds. See also *DSL*.

AGP (accelerated graphics port) Developed by Intel, AGP is a fast, dedicated interface between the video adapter or chipset and the motherboard chipset North Bridge. AGP is 32 bits wide; runs at 66MHz base speed; and can transfer 1, 2, 4, or 8 bits per cycle (1x, 2x, 4x, or 8x modes) for a throughput of up to 2,132Mbytes/sec.

aliasing Undesirable visual effects (sometimes called artifacts) in computer-generated images caused by inadequate sampling techniques. The most common effect is jagged edges along diagonal or curved object boundaries. See also *antialiasing*.

allocation unit See *cluster*.

alphanumeric characters A character set that contains only letters (A–Z) and digits (0–9). Other characters, such as punctuation marks, also might be allowed.

AMD Short for Advanced Micro Devices, the number-two PC processor maker. AMD makes the popular K6, Athlon, and Duron series of processors, as well as chipsets and flash memory devices.

ampere The basic unit for measuring electrical current. Also called amp.

AMR Short for Audio/Modem Riser, it's an Intel-developed specification for packaging modem I/O ports and a codec chip into a small card that can be installed into an AMR slot on a motherboard. Although many motherboards have AMR slots, AMR risers have not been popular, and the CNR specification has largely replaced AMR. See also *CNR*.

analog The representation of numerical values by physical variables such as voltage, current, and so on; continuously variable quantities whose values correspond to the quantitative magnitude of the variables.

analog loopback A modem self-test in which data from the keyboard is sent to the modem's transmitter, modulated into analog form, looped back to the receiver, demodulated into digital form, and returned to the screen for verification.

analog signals Continuously variable signals. Analog circuits are more subject to distortion and noise than are digital circuits but are

capable of handling complex signals with relatively simple circuitry. See also *digital signals*.

analog-to-digital converter An electronic device that converts analog signals to digital form.

AND A logic operator having the property that if P is a statement, Q is a statement, R is a statement…, then the AND of P, Q, R… is true if all statements are true and is false if any statement is false.

AND gate A logic gate in which the output is 1 only if all inputs are 1.

animation The process of displaying a sequential series of still images to achieve a motion effect.

ANSI (American National Standards Institute) A nongovernmental organization founded in 1918 to propose, modify, approve, and publish data processing standards for voluntary use in the United States. It's also the U.S. representative to the International Standards Organization (ISO) in Paris and the International Electrotechnical Commission (IEC). For more information, see the Vendor List on the DVD. Contact ANSI, 1430 Broadway, New York, NY 10018.

answer mode A state in which the modem transmits at the predefined high frequency of the communications channel and receives at the low frequency. The transmit/receive frequencies are the reverse of the calling modem, which is in originate mode. See also *originate mode*.

antialiasing Software adjustment to make diagonal or curved lines appear smooth and continuous in computer-generated images. See also *aliasing*.

antistatic mat A pad placed next to a computer upon which components are placed while servicing the system to prevent static damage. Also can refer to a larger-sized mat below an entire computer desk and chair to discharge static from a user before he touches the computer.

antivirus Software that prevents files containing viruses from running on a computer or software that detects, repairs, cleans, or removes virus-infected files.

APA (all points addressable) A mode in which all points of a displayable image can be controlled by the user or a program.

aperture grille A type of shadow mask used in CRTs. The most common is used in Sony's Trinitron monitors, which use vertical phosphor stripes and vertical slots in the mask, compared to the traditional shadow mask that uses phosphor dots and round holes in the mask. See also *shadow mask*.

API (application program interface) A system call (routine) that gives programmers access to the services provided by the operating system. In IBM-compatible systems, the ROM BIOS and DOS together present an API that a programmer can use to control the system hardware.

APM (Advanced Power Management) A specification sponsored by Intel and Microsoft originally proposed to extend the life of batteries in battery-powered computers. It is now used in desktop computers as well. APM enables application programs, the system BIOS, and the hardware to work together to reduce power consumption. An APM-compliant BIOS provides built-in power-management services to the operating system. The application software communicates power-saving data via predefined APM interfaces. Replaced in newer systems by ACPI. See also *ACPI*.

application End-user–oriented software, such as a word processor, spreadsheet, database, graphics editor, game, or Web browser.

Application Layer See *OSI*.

arbitration A method by which multiple devices attached to a single bus can bid or arbitrate to get control of that bus.

archive bit The bit in a file's attribute byte that sets the archive attribute. Tells whether the file has been changed since it last was backed up.

archive file A collection of files that has been stored (often in a compressed format)

within a single file. Zip and CAB files are the most common types of archive file formats used with Windows–based PCs. See also *Zip file* and *CAB file*.

archive medium A storage medium (floppy disk, tape cartridge, or removable cartridge) to hold files that need not be accessible instantly.

ARCnet (Attached Resource Computer Network) A baseband, token-passing LAN technology offering a flexible bus/star topology for connecting personal computers. Operating at 2.5Mbit/sec, it is one of the oldest LAN systems and was popular in low-cost networks. It was originally developed by John Murphy of Datapoint Corporation, although ARCnet interface cards are available from a variety of vendors.

areal density A calculation of the bit density (bits per inch, or BPI) multiplied by the track density (tracks per inch, or TPI), which results in a figure indicating how many bits per square inch are present on the disk surface.

ARQ (automatic repeat request) A general term for error-control protocols that feature error detection and automatic retransmission of defective blocks of data.

ASCII (American Standard Code for Information Interchange) A standard 7-bit code created in 1965 by Robert W. Bemer to achieve compatibility among various types of data processing equipment. The standard ASCII character set consists of 128 decimal numbers ranging from 0 to 127, which are assigned to letters, numbers, punctuation marks, and the most common special characters. In 1981, IBM introduced the extended ASCII character set with the IBM PC, extending the code to 8 bits and adding characters from 128 to 255 to represent additional special mathematical, graphics, and foreign characters.

ASCII character A 1-byte character from the ASCII character set, including alphabetic and numeric characters, punctuation symbols, and various graphics characters.

ASME (American Society of Mechanical Engineers; `http://www.asme.org/`) ASME International has nearly 600 codes and standards in print, and its many committees involve more than 3,000 individuals, mostly engineers but not necessarily members of the society. The standards are used in more than 90 countries throughout the world.

aspect ratio The measurement of a film or television viewing area in terms of relative height and width. The aspect ratio of most modern motion pictures varies from 3:5 to as large as 3:7, which creates a problem when a wide-format motion picture is transferred to the more square-shaped television screen, with its aspect ratio of 3:4.

assemble The act of translating a program expressed in an assembler language into a computer machine language.

assembler language A computer-oriented language whose instructions are usually in one-to-one correspondence with machine language instructions.

asymmetrical modulation A duplex transmission technique that splits the communications channel into one high-speed channel and one slower channel. During a call under asymmetrical modulation, the modem with the greater amount of data to transmit is allocated the high-speed channel. The modem with less data is allocated the slow, or back, channel. The modems dynamically reverse the channels during a call if the volume of data transfer changes.

asynchronous communication Data transmission in which the length of time between transmitted characters can vary. Timing depends on the actual time for the transfer to take place, as opposed to synchronous communication, which is timed rigidly by an external clock signal. Because the receiving modem must be signaled about when the data bits of a character begin and end, start and stop bits are added to each character. See also *synchronous communication*.

asynchronous memory Memory that runs using a timing or clock rate different from (usually slower than) the motherboard speed.

AT clock Refers to the Motorola 146818 real-time clock (RTC) and CMOS RAM chip, which first debuted in the IBM AT and whose function has been present in all PC-compatible systems since. Keeps track of the time of day and makes this data available to the operating system or other software.

ATA (AT Attachment Interface) An IDE disk interface standard introduced in March 1989 that defines a compatible register set, a 40-pin connector, and its associated signals. See also *IDE*.

ATA-2 The second-generation AT Attachment Interface specification, approved in 1996. This version defines faster transfer modes and logical block addressing schemes to allow high-performance, large-capacity drives. Also called Fast ATA, Fast ATA-2, and enhanced IDE (EIDE).

ATA-3 Published in 1997, ATA-3 defines 8-bit DMA transfers and S.M.A.R.T. support for drive failure prediction.

ATA/ATAPI-4 The fourth-generation ATA specification was published in 1998. ATA/ATAPI-4 incorporates ATAPI and adds Ultra DMA/33 (33MBps) transfer mode; APM support; an optional 80-wire, 40-pin cable; support for Compact Flash memory devices; and enhanced BIOS support for larger drives.

ATA/ATAPI-5 Approved in 2000, ATA/ATAPI-5 includes UDMA/66 support, mandates the 80-wire cable for UDMA/66, detects the cable type, and allows UDMA/66 or faster speeds only if the 80-wire cable is present.

ATA/ATAPI-6 The latest draft standard, ATA/ATAPI-6 includes UDMA/100 (100MBps) support and increases the ATA drive size limit to 144.12PB (petabytes). See also *petabyte*.

ATAPI (AT Attachment Packet Interface) A specification that defines device-side characteristics for an IDE-connected peripheral, such as a CD-ROM or tape drive. ATAPI is essentially an adaptation of the SCSI command set to the IDE interface. ATA-4 and newer ATA standards include ATAPI standards.

Athlon An AMD sixth-generation processor family roughly comparable to the Intel Pentium III and Pentium 4. Later models (beginning with the Thunderbird core) include on-die L2 cache running at full core speed. It includes MMX and AMD 3DNow! instructions for multimedia performance. Originally available in a Slot-A cartridge package, all Athlons are now available only in the Socket-A (462-pin) package. The Athlon 4 is designed for mobile applications, the Athlon MP is designed for workstation/server multiprocessor configurations, and the Athlon XP is designed mainly for single processor applications. All three use the improved Palomino core and 3DNow! Professional multimedia extensions. The Athlon XP processors include AMD's new QuantiSpeed design for faster internal operation and are rated by their performances relative to the Intel Pentium 4, rather than by their clock speeds. For example, the Athlon XP 1900+, which performs comparably to the Pentium 4 1.9GHz processor, runs at a clock speed of about 1.6GHz.

ATM (asynchronous transfer mode) A high-bandwidth, low-delay, packet-like switching and multiplexing technique. Usable capacity is segmented into fixed-size cells consisting of header and information fields, allocated to services on demand.

attribute byte A byte of information, held in the directory entry of any file or folder, that describes various attributes of the file or folder, such as whether it is read-only or has been backed up since it last was changed. Attributes can be set by the DOS `ATTRIB` command or with Windows Explorer.

ATX A motherboard and power supply form factor standard designed by Intel and introduced in 1995. It is characterized by a double row of rear external I/O connectors on the motherboard, a single keyed power supply connector, memory and processor locations that are designed not to interfere with the installation of adapter cards, and an improved cooling flow. The current specification—ATX 2.0—was introduced in December 1996.

audio A signal that can be heard, such as through the speaker of the PC. Many PC

diagnostic tests use both visual (onscreen) codes and audio signals.

audio frequencies Frequencies that can be heard by the human ear (approximately 20Hz–20,000Hz).

auto-answer A setting in modems enabling them to answer incoming calls over the phone lines automatically.

auto-dial A feature in modems enabling them to dial phone numbers without human intervention.

auto-disconnect A modem feature that enables a modem to hang up the telephone line when the modem at the other end hangs up.

AUTOEXEC.BAT A special batch file DOS and Windows 9x execute at startup. Contains any number of DOS commands that are executed automatically, including the capability to start programs at startup. See also *batch file*.

automatic head parking Disk drive head parking performed whenever the drive is powered off. Found in all modern hard disk drives with a voice-coil actuator.

auto-redial A modem or software feature that automatically redials the last number dialed if the number is busy or does not answer.

available memory Memory currently not in use by the operating system, drivers, or applications, which can be used to load additional software.

average access time The average time it takes a disk drive to begin reading any data placed anywhere on the drive. This includes the average seek time, which is when the heads are moved, as well as the latency, which is the average amount of time required for any given data sector to pass underneath the heads. Together, these factors make up the average access time. See also *average seek time* and *latency*.

average latency The average time required for any byte of data stored on a disk to rotate under the disk drive's read/write head. Equal to one-half the time required for a single rotation of a platter.

average seek time The average amount of time it takes to move the heads from one random cylinder location to another, usually including any head settling time. In many cases, the average seek time is defined as the seek time across one third of the total number of cylinders.

AVI (audio video interleave) A storage technique developed by Microsoft for its Video for Windows product that combines audio and video into a single frame or track, saving valuable disk space and keeping audio in synchronization with the corresponding video. AVI files are widely supported by media players and video production programs.

AWG American Wire Gauge, a U.S. standard for measuring the thickness of copper and aluminum wire for electrical and data-transmission use. Thinner wire is used to save space and for short distances, but thicker wire has less resistance and is better for long wire runs.

B Channel The bearer channel in an ISDN network, it's used to carry data at a rate of 64KBps. See also *BRI*.

backbone The portion of the Internet or wide area network (WAN) transmission wiring that connects the main Internet/WAN servers and routers and is responsible for carrying the bulk of the Internet/WAN data.

backplane A rarely used motherboard design in which the components typically found on a motherboard are instead located on an expansion adapter card plugged into a slot. In these systems, the board with the slots is the backplane.

backup The process of duplicating a file or library onto a separate piece of media. It's good insurance against the loss of an original.

backup disk Contains information copied from another disk. Used to ensure that original information is not destroyed or altered.

backward compatibility The design of software and hardware to work with previous versions of the same software or hardware.

bad sector A disk sector that can't hold data reliably because of a media flaw or damaged format markings.

bad track table A label affixed to the casing of an ST412/506 or ESDI hard disk drive that tells which tracks are flawed and incapable of holding data. The listing is entered into the low-level formatting program. Modern ATA (IDE) and SCSI drives are low-level formatted during manufacture and don't have (or need) a bad track table.

balanced signal Refers to signals consisting of equal currents moving in opposite directions. When balanced or nearly balanced signals pass through twisted-pair lines, the electromagnetic interference effects—such as crosstalk caused by the two opposite currents—largely cancel each other out. Differential signaling (used by some types of SCSI interfaces) is a method that uses balanced signals.

balun Short for balanced/unbalanced. A type of transformer that enables balanced cables to be joined with unbalanced cables. Twisted-pair (balanced) cables, for example, can be joined with coaxial (unbalanced) cables if the proper balun transformer is used.

bandwidth 1) Generally, the measure of the range of frequencies within a radiation band required to transmit a particular signal. The difference between the lowest and highest signal frequencies. The bandwidth of a computer monitor is a measure of the rate at which a monitor can handle information from the display adapter. The wider the bandwidth, the more information the monitor can carry and the greater the resolution. 2) Used to describe the data-carrying capacity of a given communications circuit or pathway. The bandwidth of a circuit is a measure of the rate at which information can be passed.

bank The collection of memory chips or modules that make up a block of memory readable or writable by the processor in a single cycle. This block, therefore, must be as large as the data bus of the particular microprocessor. In PC systems, the processor data bus (and therefore the bank size) is usually 8, 16, 32, or 64 bits wide. Optionally, some systems also incorporate an additional parity or ECC bit for each 8 data bits, resulting in a total of 9, 18, 36, or 72 bits (respectively) for each bank. Memory in a PC always must be added or removed in full-bank increments. The number of memory chips or modules that make up a bank varies with the width of the memory in bits and the size of the processor's data bus. For example, a K6-2 processor has a data bus that is 64 bits wide. If the motherboard uses 72-pin SIMMs (which are 32 data bits wide), a bank is two SIMMs. However, if the motherboard uses DIMMs, which are 64 data bits wide, a bank is one DIMM.

bar code The code used on consumer products and inventory parts for identification purposes. Consists of bars of varying thickness that represent characters and numerals that are read with an optical reader. The most common version is called the universal product code (UPC).

base-2 Refers to the computer numbering system that consists of two numerals: 0 and 1. Also called binary.

base address Starting location for a consecutive string of memory or I/O addresses/ports.

base memory The amount of memory available to the operating system or application programs within the first megabyte, accessible in the processor's real mode.

baseband transmission The transmission of digital signals over a limited distance. ARCnet and Ethernet local area networks use baseband signaling. Contrasts with broadband transmission, which refers to the transmission of analog signals over a greater distance.

BASIC (Beginner's All-purpose Symbolic Instruction Code) A popular computer programming language originally developed by John Kemeny and Thomas Kurtz in the mid-1960s at Dartmouth College. Normally, BASIC is an interpretive language, meaning that each statement is translated and executed as it is encountered, but it can be a compiled language, in which all the program statements are compiled before execution. Microsoft

Visual Basic, a popular development environment for Windows, is not related to BASIC.

batch file A set of commands stored in a disk file for execution by the operating system. A special batch file called `AUTOEXEC.BAT` is executed by DOS each time the system is started. All DOS and Windows batch files have a .BAT file extension.

baud A unit of signaling speed denoting the number of discrete signal elements that can be transmitted per second. The word baud is derived from the name of J.M.E. Baudot (1845–1903), a French pioneer in the field of printing telegraphy and the inventor of Baudot code. Although technically inaccurate, baud rate commonly is used to mean bit rate. Because each signal element or baud can translate into many individual bits, bits per second (bps) usually differs from baud rate. A rate of 2,400 baud means that 2,400 frequency or signal changes per second are being sent, but each frequency change can signal several bits of information. For example, 33.6Kbps modems actually transmit at only 2,400 baud.

Baudot code A 5-bit code used in many types of data communications, including teletype (TTY), radio teletype (RTTY), and telecommunications devices for the deaf (TDD). Baudot code has been revised and extended several times. See also *baud*.

bay An opening in a computer case or chassis that holds disk drives.

BBS (bulletin board system) A computer that operates with a program and a modem to enable other computers with modems to communicate with it, often on a round-the-clock basis. Thousands of PC IBM- and Apple-related BBSes offer a wealth of information and public-domain software that can be downloaded.

benchmark A test or set of tests designed to compare the performance of hardware or software. A popular set of benchmarks for PC hardware is the Ziff Davis Media benchmarks, which you can download from `http://www.zdnet.com`.

bezel A cosmetic panel that covers the face of a drive or some other device.

Bézier curve A mathematical method for describing a curve, often used in illustration and CAD programs to draw complex shapes.

bidirectional 1) Refers to lines over which data can move in two directions, such as a data bus or telephone line. 2) Refers to the capability of a printer to print from right to left and from left to right alternately.

binary See *base-2*.

BIOS (basic input/output system) The part of an operating system that handles the communications between the computer and its peripherals. Often burned into read-only memory (ROM) chips or rewritable flash (EEPROM) memory chips found on motherboards and expansion cards, such as video cards and SCSI and ATA/IDE host adapters.

bipolar A category of semiconductor circuit design that was used to create the first transistor and the first integrated circuit. Bipolar and CMOS are the two major transistor technologies. Almost all personal computers use CMOS technology chips. CMOS uses far less energy than bipolar.

bisynchronous (binary synchronous control) An earlier protocol developed by IBM for software applications and communicating devices operating in synchronous environments. The protocol defines operations at the link level of communications—for example, the format of data frames exchanged between modems over a phone line.

bit binary digit Represented logically by 0 or 1 and electrically by 0 volts and (typically) 5 volts. Other methods are used to represent binary digits physically (tones, different voltages, lights, and so on), but the logic is always the same.

bit density Expressed as bits per inch (BPI). Defines how many bits can be written onto one linear inch of a track. Sometimes also called linear density.

bit depth The number of bits used to describe the color of each pixel on a computer display. For example, a bit depth of two means the monitor can display only black and white

pixels; a bit depth of four means the monitor can display 16 different colors; a bit depth of eight allows for 256 colors; and so on.

bitmap A method of storing graphics information in memory, in which a bit devoted to each pixel (picture element) onscreen indicates whether that pixel is on or off. A bitmap contains a bit for each point or dot on a video display screen and enables fine resolution because any point or pixel onscreen can be addressed. A greater number of bits can be used to describe each pixel's color, intensity, and other display characteristics.

blank or blanking interval A period in which no video signal is received by a monitor while the videodisc or digital video player searches for the next video segment or frame to display.

block A string of records, words, or characters formed for technical or logic reasons and to be treated as an entity.

block diagram The logical structure or layout of a system in graphics form. Does not necessarily match the physical layout and does not specify all the components and their interconnections.

Blue Book The standard for enhanced CDs (CD-E). CD-E media contains both music (for play on standard CD players) and computer content. Developed by Philips and Sony in 1995.

blue screen of death A system crash in Windows that replaces the normal desktop with a blue screen with white text reporting the problem and locks up the system. Also referred to as a BSOD, this condition can be triggered by defective memory, file system errors, and other system problems.

Bluetooth An emerging short-range networking standard, Bluetooth is designed to enable PCs, mobile phones, and PDAs to exchange data with each other. Bluetooth uses the same 2.4GHz frequency range used by some types of wireless phones and by the IEEE 802.11b Wi-Fi wireless Ethernet network. Bluetooth has a speed of 1Mbps or 2Mbps, depending on the version.

BMP A Windows graphics format that can be device dependent or independent. Device-independent BMP files (DIB) are coded for translation to a wide variety of displays and printers.

BNC (Bayonet-Neill-Concelman) Also known as British-Naval-Connector, Baby-N-Connector, or Bayonet-Nut-Coupler, this bayonet-locking connector is noted for its excellent shielding and impedance-matching characteristics, resulting in low noise and minimal signal loss at any frequency up to 4GHz. It is used in Ethernet 10BASE-2 networks (also known as IEEE 802.3 or Thinnet) to terminate coaxial cables. It is also used for some high-end video monitors. BNC is named for its connection type (bayonet) and its co-developers.

bonding In ISDN, joining two 64Kbps B-channels to achieve 128Kbps speed. Bonding can also be used with analog modems that use the Multilink Point-to-Point protocol that is supported by Windows 98 and newer versions but by only a few ISPs.

Boolean operation Any operation in which each of the operands and the result take one of two values. A Boolean search can be performed with many search engines used on Web sites and help files using operators such as `AND`, `OR`, and `NOT`.

boot To load a program into the computer. The term comes from the phrase "pulling a boot on by the bootstrap."

boot manager A program that enables you to select which active partition to boot from. Often supplied with aftermarket disk-partitioning programs, such as PartitionMagic, or installed by default when you install a Windows upgrade into a separate disk partition instead of replacing your old version.

boot record The first sector on a disk or partition that contains disk parameter information for the BIOS and operating system as well as bootstrap loader code that instructs the system how to load the operating system files into memory, thus beginning the initial boot sequence to boot the machine.

boot sector See *boot record*.

boot sector virus A virus designed to occupy the boot sector of a disk. Any attempt to start or boot a system from this disk transfers the virus to the hard disk, after which it subsequently is loaded every time the system is started. Most PC viruses are boot sector viruses.

bootstrap A technique or device designed to bring itself into a desired state by means of its own action. The term is used to describe the process by which a device such as a PC goes from its initial power-on condition to a running condition without human intervention. See also *boot*.

boule Purified, cylindrical silicon crystals from which semiconducting electronic chips, including microprocessors, memory, and other chips, in a PC are manufactured. Also called an ingot.

bps (bits per second) The number of binary digits, or bits, transmitted per second. Sometimes confused with baud.

branch prediction A feature of fifth-generation (Pentium and higher) processors that attempts to predict whether a program branch will be taken and then fetches the appropriate following instructions.

BRI Short for basic rate interface, it's a form of ISDN used in home and small business applications. A 2B+1D BRI service has two B channels and a single D channel for signaling and control uses.

bridge In local area networks, an interconnection between two similar networks. Also the hardware equipment used to establish such an interconnection.

broadband transmission A term used to describe analog transmission. Requires modems for connecting terminals and computers to the network. Using frequency division multiplexing, many signals or sets of data can be transmitted simultaneously. The alternative transmission scheme is baseband, or digital, transmission.

brownout An AC supply voltage drop in which the power does not shut off entirely but continues to be supplied at lower-than-normal levels.

BSOD See *blue screen of death*.

bubble memory A special type of nonvolatile read/write memory introduced by Intel in which magnetic regions are suspended in crystal film and data is maintained when the power is off. A typical bubble memory chip contains about 512KB, or more than four million bubbles. Bubble memory failed to catch on because of slow access times measured in several milliseconds. It has, however, found a niche use as solid-state "disk" emulators in environments in which conventional drives are unacceptable, such as in military or factory use.

buffer A block of memory used as a holding tank to store data temporarily. Often positioned between a slower peripheral device and the faster computer. All data moving between the peripheral and the computer passes through the buffer. A buffer enables the data to be read from or written to the peripheral in larger chunks, which improves performance. A buffer that is *x* bytes in size usually holds the last *x* bytes of data that moved between the peripheral and CPU. This method contrasts with that of a cache, which adds intelligence to the buffer so that the most often accessed data, rather than the last accessed data, remains in the buffer (cache). A cache can improve performance greatly over a plain buffer.

bug An error or a defect in a program; it can be corrected through program patches (for applications or operating systems) or firmware updates (for BIOS chips).

burn-in The operation of a circuit or equipment to establish that its components are stable and to screen out defective ports or assemblies.

BURN-Proof Short for buffer underrun error-proof, it's a technology developed by Sanyo to prevent buffer underruns during the

creation of CD-Rs. BURN-Proof, which has been licensed to many CD-RW drive makers, enables a drive to pause the burning process and continue after sufficient data is available in the drive's buffer. The drive and CD-mastering software must both support BURN-Proof for this feature to work. Ricoh's JustLink works in a similar fashion.

burst mode A memory-cycling technology that takes advantage of the fact that most memory accesses are consecutive in nature. After setting up the row and column addresses for a given access, using burst mode can then access the next three adjacent addresses with no additional latency.

Burst Static RAMs (BSRAMs) Short for Pipeline Burst SRAM, BSRAMs are a common type of static RAM chip used for memory caches where access to subsequent memory locations after the first byte is accessed takes fewer machine cycles.

bus A linear electrical signal pathway over which power, data, and other signals travel. It is capable of connecting to three or more attachments. A bus is generally considered to be distinct from radial or point-to-point signal connections. The term comes from the Latin *omnibus*, meaning "for all." When used to describe a topology, bus always implies a linear structure.

bus mouse An obsolete type of mouse used in the 1980s that plugs into a special mouse expansion board (occasionally incorporated into a video card) instead of a serial port or motherboard mouse port. The bus mouse connector looks similar to a motherboard mouse (sometimes called PS/2 mouse) connector, but the pin configurations are different and not compatible.

busmaster An intelligent device that, when attached to the Micro Channel, EISA, VLB, or PCI bus, can bid for and gain control of the bus to perform its specific task without processor intervention. Most recent motherboards incorporate busmastering ATA/IDE host adapters, but this feature must be enabled in both the BIOS and through the installation of Windows drivers to be effective.

byte A collection of bits that makes up a character or other designation. Generally, a byte is 8 data bits. When referring to system RAM, an additional parity (error-checking) bit is also stored (see *parity*), making the total 9 bits.

C A high-level computer programming language. A programming language frequently used on mainframes, minis, and PC computer systems. C++ is a popular variant.

C3 A Socket 370-compatible processor developed by VIA Technology from the Cyrix "Joshua" after VIA purchased Cyrix from National Semiconductor. The C3 is noted for its very small die size and cool operation, making it a suitable choice for portable computers and embedded computers.

CAB file Short for cabinet file, the archive file type used by Microsoft to distribute recent versions of Windows and applications. Some recent versions of WinZip can be used to manually extract files from a .CAB file; you can also open .CAB files within Windows Explorer with Windows 98 after you install the Windows 98 Plus! package and with Windows Explorer in Windows 2000, Windows Me, and Windows XP.

cable modem A broadband Internet device that receives data through the cable TV system. The cable modem can be a one-way device (using a conventional analog modem for dialing and uploading) or a two-way device.

CableLabs Certified Cable Modem A cable modem that meets the Data or Cable Service Interface Specifications (DOCSIS) standards for modulation and protocols. Various brands and models of modems meet this standard on cable networks that also meet this standard. DOCSIS/CableLabs Certified Cable Modems can be purchased as well as leased.

cache An intelligent buffer. By using an intelligent algorithm, a cache contains the data accessed most often between a slower peripheral device and the faster CPU. See also *L1 cache*, *L2 cache*, and *disk cache*.

caddy A cartridge designed to hold a CD or DVD disc. Some CD drives use caddies, particularly in harsh or industrial environments. DVD-RAM drives also use a caddy to protect the disc.

CAM (Common Access Method) A committee formed in 1988 that consists of several computer peripheral suppliers and is dedicated to developing standards for a common software interface between SCSI peripherals and host adapters.

candela Abbreviated cd, a candela is the standard unit of measurement for luminosity. The brightness of LCDs and other types of displays is sometimes measured in cd units.

capacitor A device consisting of two plates separated by insulating material and designed to store an electrical charge.

card A printed circuit board containing electronic components that form an entire circuit, usually designed to plug into a connector or slot. Sometimes also called an adapter.

card edge connector See *edge connector*.

CardBus A PC Card (PCMCIA) specification for a 32-bit interface that runs at 33MHz and provides 32-bit data paths to the computer's I/O and memory systems, as well as a new shielded connector that prevents CardBus devices from being inserted into slots that do not support the latest version of the PC Card (PCMCIA) standard.

carpal tunnel syndrome A painful hand injury that gets its name from the narrow tunnel in the wrist that connects ligament and bone. When undue pressure is put on the tendons, they can swell and compress the median nerve, which carries impulses from the brain to the hand, causing numbness, weakness, tingling, and burning in the fingers and hands. Computer users get carpal tunnel syndrome primarily from improper keyboard ergonomics that result in undue strain on the wrist and hand.

carrier A continuous frequency signal capable of being either modulated or impressed with another information-carrying signal. The reference signal used for the transmission or reception of data. The most common use of this signal with computers involves modem communications over phone lines. The carrier is used as a signal on which the information is superimposed.

carrier detect signal A modem interface signal that indicates to the attached data terminal equipment (DTE) that it is receiving a signal from the distant modem. Defined in the RS-232 specification. Same as the received line-signal detector.

CAT Short for category, it describes the ANSI/EIA 568 wiring standards used for data transmission. The most common CAT standards include CAT 3 (16Mbps maximum data rate, suitable for 10BASE-T Ethernet) and CAT 5 (used for 100BASE-T Fast Ethernet or 1000BASE-T Gigabit Ethernet).

cathode ray tube (CRT) A device that contains electrodes surrounded by a glass sphere or cylinder and displays information by creating a beam of electrons that strike a phosphor coating inside the display unit. This device is most commonly used in computer monitors and terminals.

CAV (constant angular velocity) An optical disk recording format in which the data is recorded on the disk in concentric circles. CAV disks are rotated at a constant speed. This is similar to the recording technique used on floppy disk drives. CAV limits the total recorded capacity compared to CLV (constant linear velocity), which also is used in optical recording. See also *CLV*.

CCITT An acronym for the Comité Consultatif International de Télégraphique et Téléphonique (in English, the International Telegraph and Telephone Consultative Committee or the Consultative Committee for International Telegraph and Telephone). Renamed ITU (International Telecommunications Union). See also *ITU*.

CCS (common command set) A set of SCSI commands specified in the ANSI SCSI-1 Standard X3.131-1986 Addendum 4.B. All SCSI

devices must be capable of using the CCS to be fully compatible with the ANSI SCSI-1 standard.

CD (compact disc or compact audio disc) A 4.75" (12cm) optical disc that contains information encoded digitally in the constant linear velocity (CLV) format. This popular format for high-fidelity music offers 90 decibels signal/noise ratio, 74 minutes of digital sound, and no degradation of quality from playback. The standards for this format (developed by NV Philips and Sony Corporation) are known as the Red Book. The official (and rarely used) designation for the audio-only format is CD-DA (compact disc-digital audio). The simple audio format is also known as CD-A (compact disc-audio). A smaller (3") version of the CD is known as CD-3.

CD burner Refers to either a CD-R or CD-RW drive.

CD+G (Compact Disc+Graphics) A CD format that includes extended graphics capabilities as written into the original CD-ROM specifications. Includes limited video graphics encoded into the CD subcode area. Developed and marketed by Warner New Media.

CD-I (Compact Disc-Interactive) A compact disc format released in October 1991 that provides audio, digital data, still graphics, and motion video. The standards for this format (developed by NV Philips and Sony Corporation) are known as the Green Book. CD-I did not catch on with consumers and is now considered obsolete.

CD+MIDI (Compact Disc+Musical Instrument Digital Interface) A CD format that adds to the CD+G format digital audio, graphics information, and musical instrument digital interface (MIDI) specifications and capabilities. Developed and marketed by Warner New Media.

CD-R (Compact Disc-Recordable, sometimes called CD-writable) CD-R discs are compact discs that can be recorded and read as many times as desired. CD-R is part of the Orange Book standard defined by ISO. CD-R technology is used for mass production of multimedia applications. CD-R discs can be compatible with CD-ROM, CD-ROM XA, and CD audio. Orange Book specifies multisession capabilities, which enable data recording on the disc at various times in several recording sessions. Kodak's Photo CD is an example of CD-R technology and fits up to 100 digital photographs on a single CD. Multisession capability enables several rolls of 35mm film to be added to a single disc on different occasions.

CD-ROM (compact disc-read-only memory) A 4.75" laser-encoded optical memory storage medium with the same constant linear velocity (CLV) spiral format as audio CDs and some videodiscs. CD-ROMs can hold about 650MB of data and require more error-correction information than the standard prerecorded compact audio discs. The standards for this format (developed by NV Philips and Sony Corporation) are known as the Yellow Book. See also *CD-ROM XA*.

CD-ROM drive A device that retrieves data from a CD-ROM disc; it differs from a standard audio CD player by the incorporation of additional error-correction circuitry. CD-ROM drives usually can also play music from audio CDs.

CD-ROM XA (compact disc-read-only memory extended architecture) The XA standard was developed jointly by Sony, Philips, and Microsoft in 1988 and is now part of the Yellow Book standard. XA is a built-in feature of newer CD-ROM drives and supports simultaneous sound playback with data transfer. Non-XA drives support either sound playback or data transfer, but not both simultaneously. XA also enables data compression right on the disk, which also can increase data transfer rates.

CD-RW (compact disc-rewritable) A type of rewritable CD-ROM technology defined in Part III of the Orange Book standard that uses a different type of disc, which the drive can rewrite at least 1,000 times. CD-RW drives also can be used to write CD-R discs, and they can read CD-ROMs. CD-RWs have a

lower reflectivity than standard CD-ROMs, and CD-ROM drives must be of the newer multi-read variety to read them. CD-RW was initially known as CD-E (for CD-erasable).

CD Video A CD format introduced in 1987 that combines 20 minutes of digital audio and 6 minutes of analog video on a standard 4.75" CD. Upon introduction, many firms renamed 8" and 12" videodiscs CDV in an attempt to capitalize on the consumer popularity of the audio CD. The term fell out of use in 1990 and was replaced in some part by "laser disc" and, more recently, "DVD."

CD-WO (compact disc-write once) A variant on CD-ROM that can be written to once and read many times; developed by NV Philips and Sony Corporation. Also known as CD-WORM (CD-write once/read many), CD-recordable, or CD-writable. Standards for this format are known as the Orange Book.

CD-WORM See *CD-WO*.

CDMA Short for code division multiple access, a popular family of wireless protocols used in cellular phones for Internet and email access.

Celeron A low-cost version of the Pentium II and Pentium III processors with less L2 cache.

Centronics connector Refers to one of two types of cable connectors used with either parallel (36-pin edge connector) or SCSI (50-pin edge connector) devices.

ceramic substrate A thin, flat, fired-ceramic part used to hold an IC chip (usually made of beryllium oxide or aluminum oxide).

CERN (Conseil Européen pour la Recherche Nucléaire; The European Laboratory for Particle Physics) The site in Geneva where the World Wide Web was created in 1989.

CGA (color graphics adapter) A type of PC video display adapter introduced by IBM on August 12, 1981, which supports text and graphics. Text is supported at a maximum resolution of 80×25 characters in 16 colors with a character box of 8×8 pixels. Graphics are supported at a maximum resolution of 320×200 pixels in 16 colors or 640×200 pixels in 2 colors. The CGA outputs a TTL (digital) signal with a horizontal scanning frequency of 15.75KHz and supports TTL color or NTSC composite displays.

channel 1) Any path along which signals can be sent. 2) In ISDN, data bandwidth is divided into two B-channels that bear data and one D-channel that carries information about the call.

character A representation—coded in binary digits—of a letter, number, or other symbol.

character set All the letters, numbers, and characters a computer can use to represent data. The ASCII standard has 256 characters, each represented by a binary number from 1 to 256. The ASCII set includes all the letters in the alphabet, numbers, most punctuation marks, some mathematical symbols, and other characters.

charge coupled device A light-sensing and storage device used in scanners and digital cameras to capture the pixels.

check bit See *parity*.

checksum Short for *summation check*, a technique for determining whether a package of data is valid. The package, a string of binary digits, is added up and compared with the expected number.

chip Another name for an IC, or integrated circuit. Housed in a plastic or ceramic carrier device with pins for making electrical connections.

chip carrier A ceramic or plastic package that carries an integrated circuit.

chipset A single chip or pair of chips that integrates into it the clock generator, bus controller, system timer, interrupt controller, DMA controller, CMOS RAM/clock, and keyboard controller. See also *North Bridge* and *South Bridge*.

CHS (cylinder head sector) The term used to describe the nontranslating scheme used by the BIOS to access IDE drives that are less than or equal to 528MB in capacity. See also *LBA*.

CIF (common image format) The standard sample structure that represents the picture information of a single frame in digital HDTV, independent of frame rate and sync/blank structure. The uncompressed bit rate for transmitting CIF at 29.97 frames/sec is 36.45Mbps.

circuit A complete electronic path.

circuit board The collection of circuits gathered on a sheet of plastic, usually with all contacts made through a strip of pins. The circuit board usually is made by chemically etching metal-coated plastic.

CISC (complex instruction set computer) Refers to traditional computers that operate with large sets of processor instructions. Most modern computers, including the Intel 80xxx processors, are in this category. CISC processors have expanded instruction sets that are complex in nature and require several to many execution cycles to complete. This structure contrasts with RISC (reduced instruction set computer) processors, which have far fewer instructions that execute quickly.

clean room 1) A dust-free room in which certain electronic components (such as chips or hard disk drives) must be manufactured and serviced to prevent contamination. Rooms are rated by Class numbers. A Class 100 clean room must have fewer than 100 particles larger than 0.5 microns per cubic foot of space. 2) A legal approach to copying software or hardware in which one team analyzes the product and writes a detailed description, followed by a second team who reads the description written by the first and then develops a compatible version of the product. When done correctly, such a design methodology will survive a legal attack.

client/server A type of network in which every computer is either a server with a defined role of sharing resources with clients or a client that can access the resources on the server.

clock The source of a computer's timing signals. It synchronizes every operation of the CPU.

clock multiplier A processor feature where the internal core runs at a higher speed than the motherboard or processor bus. See also *overclocking*.

clock speed A measurement of the rate at which the clock signal for a device oscillates, usually expressed in millions of cycles per second (MHz).

clone Originally referred to an IBM-compatible computer system that physically as well as electrically emulates the design of one of IBM's personal computer systems. More currently, it refers to any PC system running an Intel or compatible processor in the 80x86 family.

cluster Also called *allocation unit*. A group of one or more sectors on a disk that forms a fundamental unit of storage to the operating system. Cluster, or allocation unit, size is determined by the operating system when the disk is formatted. Larger clusters generally offer faster system performance but waste disk space.

CLV (constant linear velocity) An optical recording format in which the spacing of data is consistent throughout the disk and the rotational speed of the disk varies depending on which track is being read. Additionally, more sectors of data are placed on the outer tracks compared to the inner tracks of the disk, which is similar to zone recording on hard drives. CLV drives adjust the rotational speed to maintain a constant track velocity as the diameter of the track changes. CLV drives also rotate more quickly near the center of the disk and more slowly toward the edge. Rotational adjustment maximizes the amount of data that can be stored on a disk. CD audio and CD-ROM use CLV recording. See also *CAV*.

CMOS (complementary metal-oxide semiconductor) A type of chip design that

requires little power to operate. In PCs, a battery-powered CMOS memory and clock chip is used to store and maintain the clock setting and system configuration information.

CMYK (cyan magenta yellow black) The standard four-color model used for printing.

CNR Short for Communications and Networking Riser, it was developed by Intel as a replacement for the AMR. CNR enables motherboard makers to offer low-cost modem, networking, and audio features through a special expansion slot. Unlike AMR, a CNR slot can be built as a shared slot with a PCI slot. See also *AMR*.

coated media Hard disk platters coated with a reddish iron-oxide medium on which data is recorded.

coaxial cable Also called *coax cable*. A data-transmission medium noted for its wide bandwidth, immunity to interference, and high cost compared to other types of cable. Signals are transmitted inside a fully shielded environment, in which an inner conductor is surrounded by a solid insulating material and then an outer conductor or shield. Used in many local area network systems, such as Ethernet and ARCnet.

COBOL (Common Business-Oriented Language) A high-level computer programming language used primarily by some larger companies. It has never achieved popularity on personal and small business computers.

code page A table used in DOS 3.3 and later that sets up the keyboard and display characters for various foreign languages.

code page switching A DOS feature in versions 3.3 and later that changes the characters displayed onscreen or printed on an output device. Primarily used to support foreign-language characters. Requires an EGA or better video system and an IBM-compatible graphics printer.

CODEC (coder-decoder) A device that converts voice signals from their analog form to digital signals acceptable to more modern digital PBXs and digital transmission systems. It then converts those digital signals back to analog so you can hear and understand what the other party is saying. Also refers to compression/decompression software used in the creation of digital audio and video files, such as MP3 and MPEG, and for videophone programs.

coercivity A measurement in units of oersteds of the amount of magnetic energy to switch or "coerce" the flux change in the magnetic recording media. High-coercivity disk media require a stronger write current.

cold boot The act of starting or restarting a computer from a powered-off state. If the system is on, this requires cycling the power off and then back on. A cold boot causes all RAM to be forcibly cleared. See also *warm boot*.

collision In a LAN, if two computers transmit a packet of data at the same time on the network, the data can become garbled, which is known as a collision.

collision detection/avoidance A process used on a LAN to prevent data packets from interfering with each other and to determine whether data packets have encountered a collision and initiate a resend of the affected packets.

color graphics adapter See *CGA*.

color palette The colors available to a graphics adapter for display.

COM port A serial port on a PC that conforms to the RS-232 standard. See also *RS-232*.

COMDEX The largest international computer trade show and conference in the world. COMDEX/Fall is held in Las Vegas during October, and COMDEX/Spring usually is held in Chicago or Atlanta during April.

command An instruction that tells the computer to start, stop, or continue an operation.

`COMMAND.COM` An operating system file that is loaded last when the computer is booted. The command interpreter or user interface and program-loader portion of DOS.

command interpreter The operating system program that controls a computer's shell or user interface. The command interpreter for MS-DOS is `COMMAND.COM`; the command interpreter for Windows is `WIN.COM`; the command interpreter for NT-based versions of Windows is `CMD.COM`.

common The ground or return path for an electrical signal. If it's a wire, it usually is colored black.

common mode noise Noise or electrical disturbances that can be measured between a current- or signal-carrying line and its associated ground. Common mode noise is frequently introduced to signals between separate computer equipment components through the power distribution circuits. It can be a problem when single-ended signals are used to connect different equipment or components that are powered by different circuits.

CompactFlash An ATA flash memory card physical format approximately one third the size of a standard PC card. Often abbreviated CF or CF+, CompactFlash cards are identical in function to standard ATA Flash PC Cards (PCMCIA) but use 50 pin connectors instead of 68. ATA flash cards contain built-in disk controller circuitry to enable the card to function as a solid-state disk drive. CF cards can plug into a CompactFlash socket or with an adapter into a standard Type I or II PC Card (PCMCIA) slot.

compatible 1) In the early days of the PC industry when IBM dominated the market, a term used to refer to computers from other manufacturers that had the same features as a given IBM model. 2) In general, software or hardware that conforms to industry standards or other de facto standards so that it can be used in conjunction with or in lieu of other versions of software or hardware from other vendors in a like manner.

compiler A program that translates a program written in a high-level language into its equivalent machine language. The output from a compiler is called an object program.

complete backup A backup of all information on a hard disk, including the directory tree structure.

composite video Television picture information and sync pulses combined. The complete wave form of the color video signal composed of chrominance and luminance picture information; blanking pedestal; field, line, and color-sync pulses; and field-equalizing pulses. Some video cards have an RCA jack that outputs a composite video signal. See also *RGB*.

compressed file A file that has been reduced in size via one or more compression techniques. See also *archive file*.

computer Device capable of accepting data, applying prescribed processes to this data, and displaying the results or information produced.

computer-based training (CBT) The use of a computer to deliver instruction or training; also known as computer-aided (or assisted) instruction (CAI), computer-aided learning (CAL), computer-based instruction (CBI), and computer-based learning (CBL).

`CONFIG.SYS` A file that can be created to tell DOS how to configure itself when the machine starts up. It can load device drivers, set the number of DOS buffers, and so on.

configuration file A file kept by application software to record various aspects of the software's configuration, such as the printer it uses. Windows uses .INI files and the Windows Registry to control its configuration.

console The unit, such as a terminal or a keyboard, in your system with which you communicate with the computer.

contiguous Touching or joined at the edge or boundary, in one piece.

continuity In electronics, an unbroken pathway. Testing for continuity usually means testing to determine whether a wire or other conductor is complete and unbroken (by measuring 0 ohms). A broken wire shows infinite resistance (or infinite ohms).

control cable The wider of the two cables that connect an ST-506/412 or ESDI hard disk drive to a controller card. A 34-pin cable that carries commands and acknowledgments between the drive and controller.

controller The electronics that control a device, such as a hard disk drive, and intermediate the passage of data between the device and computer.

controller card An adapter holding the control electronics for one or more devices, such as hard disks. Ordinarily occupies one of the computer's slots.

conventional memory The first megabyte or first 640KB of system memory accessible by an Intel processor in real mode. Sometimes called base memory.

convergence Describes the capability of a color monitor to focus the three colored electron beams on a single point. Poor convergence causes the characters onscreen to appear fuzzy and can cause headaches and eyestrain.

coprocessor An additional computer processing unit designed to handle specific tasks in conjunction with the main or central processing unit.

copy protection A hardware or software scheme to prohibit making illegal copies of a program.

core An old-fashioned term for computer memory.

core speed The internal speed of a processor. With all modern processors, this speed is faster than the system bus speed, and that speed relationship is regulated by the clock multiplier in the processor.

CP/M (Control Program for Microcomputers, originally Control Program/Monitor) An operating system created by Gary Kildall, the founder of Digital Research. Created for the old 8-bit microcomputers that used the 8080, 8085, and Z-80 microprocessors. It was the dominant operating system in the late 1970s and early 1980s for small computers used in business environments.

cps (characters per second) A data transfer rate generally estimated from the bit rate and character length. At 2,400bps, for example, 8-bit characters with start and stop bits (for a total of 10 bits per character) are transmitted at a rate of approximately 240cps. Some protocols, such as V.42 and MNP, employ advanced techniques such as longer transmission frames and data compression to increase characters per second.

CPU (central processing unit) The computer's microprocessor chip; the brains of the outfit. Typically, an IC using VLSI (very-large-scale integration) technology to pack several functions into a tiny area. The most common electronic device in the CPU is the transistor, of which several thousand to several million or more are found.

crash A malfunction that brings work to a halt. A system crash usually is caused by a software malfunction, and ordinarily you can restart the system by rebooting the machine. A head crash, however, entails physical damage to a disk and probable data loss.

CRC (cyclic redundancy checking) An error-detection technique consisting of a cyclic algorithm performed on each block or frame of data by both sending and receiving modems. The sending modem inserts the results of its computation in each data block in the form of a CRC code. The receiving modem compares its results with the received CRC code and responds with either a positive or negative acknowledgment. In the ARQ protocol implemented in high-speed modems, the receiving modem accepts no more data until a defective block is received correctly.

crosstalk The electromagnetic coupling of a signal on one line with another nearby signal line. Crosstalk is caused by electromagnetic induction, where a signal traveling through a wire creates a magnetic field that induces a current in other nearby wires.

CRT (cathode-ray tube) A term used to describe a television or monitor screen tube.

current The flow of electrons, measured in amperes, or amps.

cursor The small, flashing hyphen that appears onscreen to indicate the point at which any input from the keyboard will be placed.

cycle Time for a signal to transition from one leading edge to the next leading edge.

cyclic redundancy checking See *CRC*.

cylinder The set of tracks on a disk that are on each side of all the disk platters in a stack and are the same distance from the center of the disk. The total number of tracks that can be read without moving the heads. A floppy drive with two heads usually has 160 tracks, which are accessible as 80 cylinders. A typical 4GB hard disk has 10 platters with 20 heads (19 for data and 1 servo head) and 4,000 cylinders, in which each cylinder is composed of 19 tracks.

Cyrix Originally a Texas-based maker of Intel-compatible math coprocessor chips, Cyrix later developed low-cost, plug-compatible 6x86 and 6x86MX Pentium-class processors that were manufactured by IBM and other fabricators. Cyrix also developed the first chipsets with integrated audio and video (the MediaGX series). Cyrix was later absorbed into National Semiconductor, which retained the MediaGX technology when it sold Cyrix to VIA Technologies. VIA continues to sell the VIA Cyrix MII, a low-cost Super Socket 7 processor, and the C3, developed from the Cyrix "Joshua" processor. See also *C3*.

D/A converter (DAC) A device that converts digital signals to analog form. See also *RAMDAC*.

daisy-chain Stringing up components in such a manner that the signals move serially from one to the other. Most microcomputer multiple disk drive systems are daisy-chained. The SCSI bus system is a daisy-chain arrangement, in which the signals move from computer to disk drives to tape units, and so on. USB and IEEE-1394 devices also use the daisy-chain arrangement when hubs are used.

daisywheel printer An impact printer that prints fully formed characters one at a time by rotating a circular print element composed of a series of individual spokes, each containing two characters that radiate from a center hub. Produces letter-quality output.

DAT (digital audio tape) A small cassette containing 4mm-wide tape used for storing large amounts of digital information. DAT technology emerged in Europe and Japan in 1986 as a way to produce high-quality, digital audio recordings and was modified in 1988 to conform to the digital data storage (DDS) standard for storing computer data. Raw/compressed capacities for a single tape are 2/4GB for DDS, 4/8GB for DDS-2, 12/24GB for DDS-3, and 20/40GB for DDS-4.

data 1) Groups of facts processed into information. A graphic or textural representation of facts, concepts, numbers, letters, symbols, or instructions used for communication or processing. 2) An android from the twenty-fourth century with a processing speed of 60 trillion operations per second and a storage capacity of 800 quadrillion bits, and who serves on the USS Enterprise NCC-1701-D with the rank of lieutenant commander.

data bus The connection that transmits data between the processor and the rest of the system. The width of the data bus defines the number of data bits that can be moved into or out of the processor in one cycle.

data cable Generically, a cable that carries data. Specific to HD connections, the narrower (20-pin) of two cables that connects an ST-506/412 or ESDI hard disk drive to a controller card.

data communications A type of communication in which computers and terminals can exchange data over an electronic medium.

data compression A technique in which mathematical algorithms are applied to the data in a file to eliminate redundancies and therefore reduce the size of the file. See also *lossless compression* and *lossy compression*.

Data Link Layer In networking, the layer of the OSI reference model that controls how the electrical impulses enter or leave the network cable. Ethernet and Token-Ring are the two most common examples of Data Link Layer protocols. See also *OSI*.

data separator A device that separates data and clock signals from a single encoded signal pattern. Usually, the same device performs both data separation and combination and is sometimes called an endec, or encoder/decoder.

data transfer rate The maximum rate at which data can be transferred from one device to another.

daughterboard Add-on board to increase functionality and/or memory. Attaches to the existing board.

DB-9 9-pin D-shell connector, primarily used for PC serial ports.

DB-25 25-pin D-shell connector, primarily used for PC parallel ports.

DC Direct current, such as that provided by a power supply or batteries.

DC-600 (Data Cartridge 600) A data-storage medium invented by 3M in 1971 that uses a 1/4"-wide tape 600 feet in length.

DCE (data communications equipment) The hardware that performs communication—usually a dialup modem that establishes and controls the data link through the telephone network. See also *DTE*.

D-channel In ISDN, a 16Kbps channel used to transmit control data about a connection.

DDE (dynamic data exchange) A form of interprocess communications used by Microsoft Windows to support the exchange of commands and data between two applications running simultaneously. This capability has been enhanced further with object linking and embedding (OLE).

de facto standard A software or hardware technology not officially made a standard by any recognized standards organization but that is used as a reference for consumers and vendors because of its dominance in the marketplace.

DEBUG The name of a utility program included with DOS and used for specialized purposes, such as altering memory locations, tracing program execution, patching programs and disk sectors, and performing other low-level tasks.

decibel (dB) A logarithmic measure of the ratio between two powers, voltages, currents, sound intensities, and so on. Signal-to-noise ratios are expressed in decibels.

dedicated line A user-installed telephone line that connects a specified number of computers or terminals within a limited area, such as a single building. The line is a cable rather than a public-access telephone line. The communications channel also can be referred to as nonswitched because calls do not go through telephone company switching equipment.

dedicated servo surface In voice-coil–actuated hard disk drives, one side of one platter given over to servo data that is used to guide and position the read/write heads.

default Any setting assumed at startup or reset by the computer's software and attached devices and operational until changed by the user. An assumption the computer makes when no other parameters are specified. When you type `DIR` without specifying the drive to search, for example, the computer assumes you want it to search the default drive. The term is used in software to describe any action the computer or program takes on its own with embedded values.

defect map A list of unusable sectors and tracks coded onto a drive during the low-level format process.

defragmentation The process of rearranging disk sectors so files are stored on consecutive sectors in adjacent tracks.

degauss 1) To remove magnetic charges or to erase magnetic images. Normal applications include CRT monitors and disks or tapes. Most monitors incorporate a degaussing coil, which surrounds the CRT, and automatically energize this coil for a few seconds when powered up to remove color or image distorting magnetic fields from the metal mask inside the tube. Some monitors include a button or control that can be used for additional applications of this coil to remove more stubborn magnetic

traces. 2) Also the act of erasing or demagnetizing a magnetic disk or tape using a special tool called a degaussing coil.

density The amount of data that can be packed into a certain area on a specific storage media.

desktop A personal computer that sits on a desk.

device driver Originally, a memory-resident program loaded by `CONFIG.SYS` that controls an unusual device, such as an expanded memory board. Windows also uses device drivers, but they are loaded through the Windows Registry or .INI files.

DHCP (Dynamic Host Configuration Protocol) A protocol for assigning dynamic IP addresses to devices on a network. With dynamic addressing, a device can have a different IP address every time it connects to the network.

Dhrystone A benchmark program used as a standard figure of merit indicating aspects of a computer system's performance in areas other than floating-point math performance. Because the program does not use any floating-point operations, performs no I/O, and makes no operating system calls, it is most useful for measuring the processor performance of a system. The original Dhrystone program was developed in 1984 and was written in Ada, although the C and Pascal versions became more popular by 1989.

DHTML (Dynamic HTML) A collective term for cascading style sheets, layering, dynamic fonts, and other features encompassed in standard HTML 4.0, Netscape Navigator 4.x and above, and Internet Explorer 4.x and above. Because of differences in how browsers interpret particular DHTML features, many developers incorporate browser-checking code into their Web pages to enable or disable certain features depending on the browser being used to view the page.

diagnostics Programs used to check the operation of a computer system. These programs enable the operator to check the entire system for any problems and indicate in which area the problems lie.

dialup adapter In Windows 9x/Me, a software program that uses a modem to emulate a network interface card for networking. Most commonly used to connect to an Internet service provider or a dialup server for remote access to a LAN.

die An individual chip (processor, RAM, or other integrated circuit) cut from a finished silicon chip wafer and built into the physical package that connects it to the rest of the PC or a circuit board.

differential An electrical signaling method in which a pair of lines are used for each signal in "push-pull" fashion. In most cases, differential signals are balanced so that the same current flows on each line in opposite directions. This is unlike single-ended signals, which use only one line per signal referenced to a single ground. Differential signals have a large tolerance for common-mode noise and little crosstalk when used with twisted-pair wires even in long cables. Differential signaling is expensive because two pins are required for each signal.

digital camera A type of camera that uses a sensor and internal or removable flash memory in place of film to record still images. Digital cameras' picture quality is usually rated in megapixels. See also *megapixel*.

digital loopback A test that checks the modem's RS-232 interface and the cable that connects the terminal or computer and the modem. The modem receives data (in the form of digital signals) from the computer or terminal and immediately returns the data to the screen for verification.

digital signals Discrete, uniform signals. In this book, the term refers to the binary digits 0 and 1.

digital signature An electronic identifier used to authenticate a message or the contents of a file. Windows 98 and above are designed to prefer digitally signed device drivers (drivers approved by the Windows Hardware Quality Labs) and will warn you if you try to install an unsigned device driver.

digital-to-analog converter (DAC) A device for converting digital signals to analog signals. VGA-based displays are analog, so video cards that connect to them include a DAC to convert the signals to analog to drive the display.

digitize To transform an analog wave to a digital signal a computer can store. Conversion to digital data and back is performed by a D/A converter (DAC), often a single-chip device. How closely a digitized sample represents an analog wave depends on the number of times the amplitude of a wave is measured and recorded (the rate of digitization), as well as the number of levels that can be specified at each instance. The number of possible signal levels is dictated by the resolution in bits.

DIMM (dual inline memory module) A 64-bit wide, 168-pin memory module used in Pentium and newer PCs. They are available in several versions, including 5v or 3v, buffered or unbuffered, with FPM/EDO or SDRAM memory, and in 64-bit (non-ECC/parity) or 72-bit (ECC/parity) form. Most Pentium and newer PCs require 3.3v unbuffered SDRAM DIMMs in either non-ECC or ECC versions (ECC recommended).

DIP (dual inline package) A family of rectangular, integrated-circuit flat packages that have leads on the two longer sides. Package material is plastic or ceramic.

DIP switch A tiny switch (or group of switches) on a circuit board. Named for the form factor of the carrier device in which the switch is housed.

direct memory access (DMA) A process by which data moves between a disk drive (or other device) and system memory without direct control of the central processing unit, thus freeing it up for other tasks.

Direct Rambus DRAM See *RDRAM*.

directory An area of a disk that stores the titles given to the files saved on the disk and serves as a table of contents for those files. Contains data that identifies the name of a file, the size, the attributes (system, hidden, read-only, and so on), the date and time of creation, and a pointer to the location of the file. Each entry in a directory is 32 bytes long. Windows refers to subdirectories (directories beneath the root directory) as folders.

DirectX A set of graphics-related drivers and APIs that translates generic hardware commands into specific commands for particular pieces of hardware. Developed by Microsoft, DirectX lets graphical or multimedia applications take advantage of specific features supported by various graphics accelerators.

disc Flat, circular, rotating medium that can store various types of information, both analog and digital. *Disc* is often used in reference to optical storage media, whereas *disk* refers to magnetic storage media. *Disc* also is often used as a short form for videodisc or compact audio disc (CD).

disk Alternative spelling for disc that generally refers to magnetic storage medium on which information can be accessed at random. Floppy disks and hard disks are examples.

disk access time See *access time*.

disk cache A portion of memory on the PC motherboard or on a drive interface card or controller used to store frequently accessed information from the drive (such as the file allocation table [FAT] or directory structure) to speed up disk access. With a larger disk cache, additional data from the data portion of a drive can be cached as well. See also *cache*, *L1 cache*, and *L2 cache*.

disk partition See *partition*.

display A device used for viewing information generated by a computer.

display adapter The interface between the computer and the monitor that transmits the signals which appear as images on the display. This can take the form of an expansion card or a chip built into the motherboard.

dithering The process of creating more colors and shades from a given color palette. In monochrome displays or printers, dithering varies the black-and-white dot patterns to simulate shades of gray. Grayscale dithering is used to produce different shades of gray when

the device can produce only limited levels of black or white outputs. Color screens or printers use dithering to create additional colors by mixing and varying the dot sizing and spacing. For example, when converting from 24-bit color to 8-bit color (an 8-bit palette has only 256 colors compared to the 24-bit palette's millions), dithering adds pixels of different colors to simulate the original color. Error diffusion is a type of dithering best suited for photographs.

DLC (Data Link Control) Refers to the Data Link Layer in the OSI model. Every network interface card (NIC) has a unique DLC address or DLC identifier (DLCI) that identifies the node on the network. For Ethernet networks, the DLC address is usually called the Media Access Control (MAC) address.

DLL (Dynamic Link Library) An executable driver program module for Microsoft Windows that can be loaded on demand, linked in at runtime, and subsequently unloaded when the driver is no longer needed.

DMA See *direct memory access*.

DMI (Desktop Management Interface) DMI is an operating-system– and protocol-independent standard developed by the Desktop Management Task Force (DMTF) for managing desktop systems and servers. DMI provides a bidirectional path to interrogate all the hardware and software components within a PC, enabling hardware and software configurations to be monitored from a central station in a network.

DNS (domain name system or service) An Internet service that translates domain names into numeric IP addresses. Every time you use a domain name, a DNS server must translate the name into the corresponding IP address.

docking station Equipment that enables a laptop or notebook computer to use peripherals and accessories normally associated with desktop systems.

DOCSIS See *CableLabs Certified Cable Modems*.

doping Adding chemical impurities to silicon (which is naturally a nonconductor) to create a material with semiconductor properties that is then used in the manufacturing of electronic chips.

DoS (denial of service) An Internet attack on a resource that prevents users from accessing email, Web sites, or other services. It usually exploits security shortcomings in email or Web servers.

DOS (Disk Operating System) A collection of programs stored on the DOS disk that contain routines enabling the system and user to manage information and the hardware resources of the computer. DOS must be loaded into the computer before other programs can be started.

dot-matrix printer An impact printer that prints characters composed of dots. Characters are printed one at a time by pressing the ends of selected wires against an inked ribbon and paper.

dot pitch A measurement of the width of the dots that make up a pixel. The smaller the dot pitch, the sharper the image.

double density (DD) An indication of the storage capacity of a floppy drive or disk in which eight or nine sectors per track are recorded using MFM encoding. See also *MFM encoding*.

download The process of receiving files from another computer.

downtime Operating time lost because of a computer malfunction.

DPMI (DOS Protected Mode Interface) An industry-standard interface that allows DOS applications to execute program code in the protected mode of the 286 or later Intel processor. The DPMI specification is available from Intel.

DPMS (Display Power Management Signaling) A VESA standard for signaling a monitor or display to switch into energy conservation mode. DPMS provides for two low-energy modes: standby and suspend.

DRAM (dynamic random access memory) The most common type of computer memory, DRAM can be manufactured very inexpensively compared to other types of memory. DRAM chips are small and inexpensive because they normally require only one transistor and a capacitor to represent each bit. The capacitors must be energized every 15ms or so (hundreds of times per second) to maintain their charges. DRAM is volatile, meaning it loses data with no power or without regular refresh cycles.

drive A mechanical device that manipulates data storage media.

driver A program designed to interface a particular piece of hardware to an operating system or other standard software.

drum The cylindrical photoreceptor in a laser printer that receives the document image from the laser and applies it to the page as it slowly rotates.

DSL (digital subscriber line) A high-speed digital modem technology. DSL is either symmetric or asymmetric. Asymmetric provides faster downstream speeds, which is suited for Internet usage and video on demand. Symmetric provides the same rate coming and going. See also *ADSL*.

DSM (digital storage media) A digital storage or transmission device or system.

DSP (digital signal processor) Dedicated, limited-function processor often found in modems, sound cards, cellular phones, and so on.

DTE (data terminal [or terminating] equipment) The device, usually a computer or terminal, that generates or is the final destination of data. See also *DCE*.

dual cavity pin grid array Chip packaging designed by Intel for use with the Pentium Pro processor that houses the processor die in one cavity of the package and the L2 cache memory in a second cavity within the same package.

dual independent bus (DIB) architecture A processor technology with the existence of two independent buses on the processor—the L2 cache bus and the processor-to-main memory system bus. The processor can use both buses simultaneously, thus getting as much as two times more data into and out of the processor than a single bus architecture processor. The Intel Pentium Pro, Pentium II, and newer processors from Intel and AMD (such as the AMD Athlon and Duron) have DIB architecture.

dual scan display A lower-quality but economical type of LCD color display that has an array of transistors running down the x and y axes of two sides of the screen. The number of transistors determines the screen's resolution.

dumb terminal A screen and keyboard device with no inherent processing power connected to a computer that is usually remotely located.

duplex Indicates a communications channel capable of carrying signals in both directions.

Duron A low-cost version of the Athlon processor with less L2 cache. Available in the Socket A (462-pin) chip package.

DVD (digital versatile disc) Originally called digital video disc. A new type of high-capacity CD-ROM disc and drive format with up to 28 times the capacity of a standard CD-ROM. The disc is the same diameter as a CD-ROM but can be recorded on both sides and on two layers for each side. Each side holds 4.7GB on a single layer disc, whereas dual-layer versions hold 8.5GB per side, for a maximum of 17GB total if both sides and both layers are used, which is the equivalent of 28 CD-ROMs. DVD drives can read standard audio CDs and CD-ROMs.

DVD-A A DVD format designed to support high-quality music and audio. DVD-A uses 24-bit sampling at 96KHz, significantly better than CD audio (16-bit at 44.1KHz). Unlike DVD, DVD-A discs can be played on conventional CD players but produce the highest quality only when played on DVD-A players.

DVI (Digital Video Interactive) A standard that was originally developed at RCA Laboratories and sold to Intel in 1988. DVI integrates digital motion, still video, sound, graphics, and special effects in a compressed format. DVI is a highly sophisticated hardware compression technique used in interactive multimedia applications.

DVI (Digital Visual Interface) The current de facto standard for LCD displays developed by the Digital Display Working Group in April 1999. DVI-D provides digital signals only, whereas DVI-I (which is more common) provides both digital and analog signals. A DVI-I connector can be converted to VGA with an external adapter.

Dvorak keyboard A keyboard design by August Dvorak that was patented in 1936 and approved by ANSI in 1982. Provides increased speed and comfort and reduces the rate of errors by placing the most frequently used letters in the center for use by the strongest fingers. Finger motions and awkward strokes are reduced by more than 90% in comparison with the familiar QWERTY keyboard. The Dvorak keyboard has the five vowel keys, AOEUI, together under the left hand in the center row and the five most frequently used consonants, DHTNS, under the fingers of the right hand.

dynamic execution A processing technique that enables the processor to dynamically predict the order of instructions and execute them out of order internally if necessary for an improvement in speed. Uses these three techniques: Multiple Branch Prediction, Data Flow Analysis, and Speculative Execution.

E2000 Also called Energy 2000, this is a Swiss-developed standard for power management that calls for computer monitors to use only 5 watts of power when in standby mode.

EBCDIC (Extended Binary Coded Decimal Interchange Code) An IBM-developed, 8-bit code for the representation of characters. It allows 256 possible character combinations within a single byte. EBCDIC is the standard code on IBM minicomputers and mainframes, but not on the IBM microcomputers, where ASCII is used instead.

ECC (error correcting code) A type of system memory or cache that is capable of detecting and correcting some types of memory errors without interrupting processing.

ECP (enhanced capabilities port) A type of high-speed parallel port jointly developed by Microsoft and Hewlett-Packard that offers improved performance for the parallel port and requires special hardware logic. ECP ports use both an IRQ and a DMA channel. See also *IEEE 1284*.

edge connector The part of a circuit board containing a series of printed contacts that is inserted into an expansion slot or a connector.

EDO (extended data out) RAM A type of RAM chip that enables a timing overlap between successive accesses, thus improving memory cycle time.

EEPROM (electrically erasable programmable read-only memory) A type of nonvolatile memory chip used to store semipermanent information in a computer, such as the BIOS. An EEPROM can be erased and reprogrammed directly in the host system without special equipment. This is used so manufacturers can upgrade the ROM code in a system by supplying a special program that erases and reprograms the EEPROM chip with the new code. Also called flash ROM.

EGA (enhanced graphics adapter) A type of PC video display adapter first introduced by IBM on September 10, 1984, that supports text and graphics. Text is supported at a maximum resolution of 80×25 characters in 16 colors with a character box of 8×14 pixels. Graphics are supported at a maximum resolution of 640×350 pixels in 16 (from a palette of 64) colors. The EGA outputs a TTL (digital) signal with a horizontal scanning frequency of 15.75KHz, 18.432KHz, or 21.85KHz, and it supports TTL color or TTL monochrome displays.

EIA (Electronic Industries Association) An organization that defines electronic standards in the United States.

EIDE (Enhanced Integrated Drive Electronics) A specific Western Digital implementation of the ATA-2 specification. See also *ATA-2*.

EISA (Extended Industry Standard Architecture) An extension of the Industry Standard Architecture (ISA) bus developed by IBM for the AT. The EISA design was led by Compaq Corporation. Later, eight other manufacturers (AST, Epson, Hewlett-Packard, NEC, Olivetti, Tandy, Wyse, and Zenith) joined Compaq in a consortium founded September 13, 1988. This group became known as the "gang of nine." The EISA design was patterned largely after IBM's Micro Channel Architecture (MCA) in the PS/2 systems, but unlike MCA, EISA enables backward compatibility with older plug-in adapters. EISA products became obsolete after the development of the PCI slot architecture. See also *PCI*.

electronic mail (email) A method of transferring messages from one computer to another.

electrostatic discharge (ESD) The grounding of static electricity. A sudden flow of electricity between two objects at different electrical potentials. ESD is a primary cause of integrated circuit damage or failure.

ELF (extremely low frequency) A very low-frequency electromagnetic radiation generated by common electrical appliances, including computer monitors. The Swedish MPR II standard governs this and other emissions. Also called VLF (very low frequency).

embedded controller In disk drives, a controller built into the same physical unit that houses the drive rather than on a separate adapter card. IDE and SCSI drives both use embedded controllers.

embedded servo data Magnetic markings embedded between or inside tracks on disk drives that use voice-coil actuators. These markings enable the actuator to fine-tune the position of the read/write heads.

EMM (expanded memory manager) A driver that provides a software interface to expanded memory. EMMs were originally created for expanded memory boards but also can use the memory management capabilities of the 386 or later processors to emulate an expanded memory board. EMM386.EXE is an example of an EMM that comes with DOS and Windows 9x.

EMS (Expanded Memory Specification) Sometimes also called the LIM spec because it was developed by Lotus, Intel, and Microsoft. Provides a way for microcomputers running under DOS to access additional memory. EMS memory management provides access to a maximum of 32MB of expanded memory through a small (usually 64KB) window in conventional memory. EMS is a cumbersome access scheme designed primarily for pre-286 systems that could not access extended memory.

emulator A piece of test apparatus that emulates or imitates the function of a particular chip.

encoding The protocol by which data is carried or stored by a medium.

encryption The translation of data into unreadable codes to maintain security.

endec (encoder/decoder) A device that takes data and clock signals and combines or encodes them using a particular encoding scheme into a single signal for transmission or storage. The same device also later separates or decodes the data and clock signals during a receive or read operation. Sometimes called a data separator.

Energy Star A certification program started by the Environmental Protection Agency. Energy Star–certified computers and peripherals are designed to draw less than 30 watts of electrical energy from a standard 110-volt AC outlet during periods of inactivity. Also called Green PCs. See also *E2000*.

Enhanced CD (CD-E) See *Blue Book*.

enhanced graphics adapter See *EGA*.

enhanced small device interface See *ESDI*.

EPP (enhanced parallel port) A type of parallel port developed by Intel, Xircom, and Zenith Data Systems that operates at almost ISA bus speed and offers a tenfold increase in the raw throughput capability over a conventional parallel port. EPP is especially designed for parallel port peripherals, such as LAN adapters, disk drives, and tape backups. See also *IEEE 1284*.

EPROM (erasable programmable read-only memory) A type of read-only memory (ROM) in which the data pattern can be erased to allow a new pattern. EPROM usually is erased by ultraviolet light and recorded by a higher-than-normal voltage programming signal.

equalization A compensation circuit designed into modems to counteract certain distortions introduced by the telephone channel. Two types are used: fixed (compromise) equalizers and those that adapt to channel conditions (adaptive). Good-quality modems use adaptive equalization.

error control Various techniques that check the reliability of characters (parity) or blocks of data. V.42, MNP, and HST error-control protocols use error detection (CRC) and retransmission of error frames (ARQ).

error message A word or combination of words to indicate to the user that an error has occurred somewhere in the program.

ESCD (extended system configuration data) Area in CMOS or Flash/NVRAM where plug-and-play information is stored.

ESDI (Enhanced Small Device Interface) A hardware standard developed by Maxtor and standardized by a consortium of 22 disk drive manufacturers on January 26, 1983. A group of 27 manufacturers formed the ESDI steering committee on September 15, 1986, to enhance and improve the specification. A high-performance interface used primarily with hard disks, ESDI enables a maximum data transfer rate to and from a hard disk of between 10Mbit/sec and 24Mbit/sec. ESDI was replaced by IDE and SCSI interfaces. ESDI drives use the same 34-pin and 20-pin cables used by ST412/ST506 drives.

Ethernet A type of network protocol developed in the late 1970s by Bob Metcalf at Xerox Corporation and endorsed by the IEEE. One of the oldest LAN communications protocols in the personal computing industry, Ethernet networks use a collision-detection protocol to manage contention. Ethernet is defined by the IEEE 802.3 standard.

expanded memory Otherwise known as EMS memory, this is memory that conforms to the EMS specification. Requires a special device driver and conforms to a standard developed by Lotus, Intel, and Microsoft.

expansion card An integrated circuit card that plugs into an expansion slot on a motherboard to provide access to additional peripherals or features not built into the motherboard. Also referred to as an add-in board.

expansion slot A slot on the motherboard that physically and electrically connects an expansion card to the motherboard and the system buses.

extended graphics array See *XGA*.

extended memory Direct processor-addressable memory addressed by an Intel (or compatible) 286 or more advanced processor in the region beyond the first megabyte. Addressable only in the processor's protected mode of operation.

extended partition A nonbootable DOS partition (also supported by Windows) containing DOS volumes. Starting with DOS v3.3, the FDISK program can create two partitions that serve DOS: an ordinary, bootable partition (called the primary partition) and an extended partition, which can contain as many as 23 volumes from D: to Z:.

external device A peripheral installed outside the system case.

extra-high density (ED) An indication of the storage capacity of a floppy drive or disk in which 36 sectors per track are recorded using a vertical recording technique with MFM encoding.

FAQ (frequently asked questions) Name for a list of popular questions and answers covering any particular subject.

Fast-ATA (fast AT attachment interface) Also called fast ATA-2, these are specific Seagate and Quantum implementations of the ATA-2 interface. See also *ATA-2*.

Fast Ethernet Popular term for 100BASE-T and other 100Mbps versions of Ethernet. Fast Ethernet uses CAT 5 cable.

Fast Page Mode RAM A type of RAM that improves on standard DRAM speed by enabling faster access to all the data within a given row of memory by keeping the row address the same and changing only the column.

FAT (file allocation table) A table held near the outer edge of a disk that tells which sectors are allocated to each file and in what order.

FAT32 A disk file allocation system from Microsoft that uses 32-bit values for FAT entries instead of the 16-bit values used by the original FAT system, enabling partition sizes up to 2TB (terabytes). FAT32 first appeared in Windows 95B and is also found in Windows 98, Windows Me, Windows 2000, and Windows XP.

fault tolerance The capability of a computer to withstand a failure. Many levels of fault tolerance exist, and fault tolerance can be applied to several components or systems in the computer. For example, ECC (error correcting code) memory is considered fault tolerant because it is typically capable of automatically identifying and correcting single bit errors.

fax/modem A peripheral that integrates the capabilities of a fax machine and a modem in one expansion card or external unit. Almost all 14.4Kbps and faster modems sold for use in desktop or portable PCs include fax capabilities.

FC-PGA (flip-chip pin grid array) A type of chip packaging first used in the Socket PGA370 version of the Pentium III where the raw processor die has bumped contacts spaced on the face of the die and is mounted face-down to a pin grid array carrier. The heat sink is then directly attached to the back of the raw silicon die surface.

FDISK The name of the disk-partitioning program under several operating systems, including DOS and Windows 9x/Me, to create the master boot record and allocate partitions for the operating system's use.

feature connector On a video adapter, a connector that enables an additional video feature card, such as a separate 3D accelerator, video capture card, or MPEG decoder, to be connected to the main video adapter and display.

fiber optic A type of cable or connection using strands or threads of glass to guide a beam of modulated light. Allows for very high-speed signaling and multiplexing as well as the combining of many data streams along a single cable.

FIFO (first-in, first-out) A method of storing and retrieving items from a list, table, or stack so that the first element stored is the first one retrieved.

file A collection of information kept somewhere other than in random-access memory.

file attribute Information held in the attribute byte of a file's directory entry.

file compression See *compressed file*.

filename The name given to the disk file. For DOS, it must be from one to eight characters long and can be followed by a filename extension, which can be from one to three characters long. Windows 9x and above ease these constraints by allowing filenames of up to 255 characters including the directory path.

firewall A hardware or software system designed to prevent unauthorized access to or from a private network.

FireWire Also called IEEE-1394 or i.Link. A serial I/O interface standard that is extremely fast, with data transfer rates up to 400MB/sec, 800MB/sec, or 3.2GB/sec, depending on the version of standard used.

firmware Software contained in a read-only memory (ROM) device. A cross between hardware and software.

fixed disk Also called a hard disk, it's a disk that can't be removed from its controlling hardware or housing. Made of rigid material with a magnetic coating and used for the mass storage and retrieval of data.

flash ROM A type of EEPROM developed by Intel that can be erased and reprogrammed in the host system. See also *EEPROM*.

flicker A monitor condition caused by refresh rates that are too low, in which the display flashes visibly. This can cause eyestrain or more severe physical problems.

floating-point unit (FPU) Sometimes called the math coprocessor; handles the more complex calculations of the processing cycle.

floppy disk A removable disk using flexible magnetic media enclosed in a semirigid or rigid plastic case.

floppy disk controller The logic and interface that connects a floppy disk drive to the system.

floppy tape A tape standard that uses drives connecting to an ordinary floppy disk controller.

floptical drive A special type of high-capacity removable disk drive that uses an optical mechanism to properly position the drive read/write heads over the data tracks on the disk. This enables more precise control of the read/write positioning and therefore narrower track spacing and more data packed into a smaller area than traditional floppy disks. The LS-120 and LS-240 SuperDisk drives are recent examples of floptical drives.

flow control A mechanism that compensates for differences in the flow of data input to and output from a modem or other device.

FM encoding Frequency modulation encoding. An outdated method of encoding data on the disk surface that uses up half the disk space with timing signals.

FM synthesis An audio technology that uses one sine wave operator to modify another and create an artificial sound that mimics an instrument.

folder In a graphical user interface, a simulated file folder that holds documents (text, data, or graphics), applications, and other folders. A folder is similar to a DOS subdirectory.

footprint Describes the shape of something. See also *form factor*.

form factor The physical dimensions of a device. Two devices with the same form factor are physically interchangeable. The IBM PC, XT, and XT Model 286, for example, all use power supplies that are internally different but have exactly the same form factor.

FORMAT The DOS/Windows format program that performs both low- and high-level formatting on floppy disks but only high-level formatting on hard disks.

formatted capacity The total number of bytes of data that can fit on a formatted disk. The unformatted capacity is higher because space is lost defining the boundaries between sectors.

formatting Preparing a disk so the computer can read or write to it. Checks the disk for defects and constructs an organizational system to manage information on the disk.

FORTRAN (formula translator) A high-level programming language developed in 1954 by John Backus at IBM primarily for programs dealing with mathematical formulas and expressions similar to algebra and used primarily in scientific and technical applications.

fragmentation The state of having a file scattered around a disk in pieces rather than existing in one contiguous area of the disk. Fragmented files are slower to read than files stored in contiguous areas and can be more difficult to recover if the FAT or a directory becomes damaged.

frame 1) A data communications term for a block of data with header and trailer information attached. The added information usually

includes a frame number, block size data, error-check codes, and start/end indicators. 2) A single, complete picture in a video or film recording. A video frame consists of two interlaced fields of either 525 lines (NTSC) or 625 lines (PAL/SECAM), running at 30 frames per second (NTSC) or 25 frames per second (PAL/SECAM).

frame buffer A memory device that stores, pixel by pixel, the contents of an image. Frame buffers are used to refresh a raster image. Sometimes they incorporate local processing capability. The "depth" of the frame buffer is the number of bits per pixel, which determines the number of colors or intensities that can be displayed.

frame rate The speed at which video frames are scanned or displayed: 30 frames per second for NTSC and 25 frames per second for PAL/SECAM.

FTP (File Transfer Protocol) A method of transferring files over the Internet. FTP can be used to transfer files between two machines on which the user has accounts. Anonymous FTP can be used to retrieve a file from a server without having an account on that server.

full duplex Signal flow in both directions at the same time. In microcomputer communications, it also can refer to the suppression of the online local echo. 100BASE-TX network cards capable of full-duplex operations can run at an effective speed of 200Mbps when full-duplex operation is enabled.

full-height drive A drive unit that is 3 1/4" high, 5 1/4" wide, and 8" deep. Equal to two half-height drive bays.

full-motion video A video sequence displayed at full television standard resolutions and frame rates. In the U.S., this equates to NTSC video at 30 frames per second.

function keys Special-purpose keys that can be programmed to perform various operations. They serve many functions, depending on the program being used.

G.lite A popular form of ADSL, G.lite can be self-installed by the user. Also referred to as the G.992.2 standard.

gas-plasma display Commonly used in portable systems, it's a type of display that operates by exciting a gas—usually neon or an argon-neon mixture—through the application of a voltage. When sufficient voltage is applied at the intersection of two electrodes, the gas glows an orange-red. Because gas-plasma displays generate light, they require no backlighting.

gateway Officially, an application-to-application conversion program or system. For example, an email gateway converts from SMTP (Internet) email format to MHS (Novell) email format. The term gateway is also used as a slang term for router. See also *router*.

gender When describing connectors for PCs, connectors are described as male if they have pins or female if they have receptacles designed to accept the pins of a male connector.

genlocking The process of aligning the data rate of a video image with that of a digital device to digitize the image and enter it into computer memory. The machine that performs this function is known as a genlock.

Ghost Popular utility program sold by Symantec that can be used to create a compressed version of a drive's contents and clone it to one or more PCs over a network or via CD storage.

gibi A multiplier equal to 1,073,741,824.

gibibyte (Gi) A unit of information storage equal to 1,073,741,824 bytes (1,024×1,024×1,024 equals a Gi). Formerly known as a binary gigabyte. See also *gigabyte* and *kilobyte*.

GIF (Graphics Interchange Format) A popular raster graphics file format developed by CompuServe that handles 8-bit color (256 colors) and uses the LZW method to achieve compression ratios of approximately 1.5:1 to 2:1. You can reduce the size of a GIF file even more by dropping unused colors from the file.

giga A multiplier indicating one billion (1,000,000,000) of some unit. Abbreviated as g or G. The binary giga (1,073,741,824) is now referred to as a gibi. See also *gibi*.

gigabyte (GB) A unit of information storage equal to 1,000,000,000 bytes. The value formerly called a binary GB (1,073,741,824 bytes) is now called a gibibyte. See also *gibibyte*.

gigahertz GHz is used to measure the clock frequency of high-performance processors. The first 1GHz desktop processor was introduced by AMD (a 1GHz Athlon) in March 2000.

graphics accelerator A video processor or chipset specially designed to speed the display and rendering of graphical objects onscreen. Originally, accelerators were optimized for 2D or 3D operations, but all current graphics accelerators, such as NVIDIA's GeForce and ATI's RADEON series, accelerate both types of data.

graphics adapter See *video adapter*.

Green Book The standard for Compact Disc-Interactive (CD-I). Philips developed CD-I technology for the consumer market to be connected to a television instead of a computer monitor. CD-I is not a computer system but a consumer device that made a small splash in the market and disappeared. CD-I discs require special code and are not compatible with standard CD-ROMs. A CD-ROM can't be played on the CD-I machine, but Red Book audio can be played on it.

GUI (graphical user interface) A type of program interface that enables users to choose commands and functions by pointing to a graphical icon using either a keyboard or pointing device, such as a mouse. Windows is the most popular GUI available for PC systems.

half duplex Signal flow in both directions but only one way at a time. In microcomputer communications, half duplex can refer to activation of the online local echo, which causes the modem to send a copy of the transmitted data to the screen of the sending computer.

half-height drive A drive unit that is 1.625" high, 5 1/4" wide, and 8" deep.

halftoning A process that uses dithering to simulate a continuous tone image, such as a photograph or shaded drawing, using various sizes of dots. Newspapers, magazines, and many books use halftoning. The human eye merges the dots to give the impression of gray shades.

handshaking The process of exchanging information about speeds and protocols between analog modems to establish a dialup connection. If your modem volume is high enough, you can hear handshaking as a series of distinct tones at the start of a modem-to-modem call.

hard disk A high-capacity disk storage unit characterized by a normally nonremovable rigid substrate medium. The platters in a hard disk usually are constructed of aluminum or glass/ceramic. Also sometimes called a fixed disk.

hard error An error in reading or writing data caused by damaged hardware.

hard reset Resetting a system via the hardware, usually by pressing a dedicated reset button wired to the motherboard/processor reset circuitry. Does not clear memory like a cold boot does. See also *cold boot*.

hardware Physical components that make up a microcomputer, monitor, printer, and so on.

HDLC (High-Level Data Link Control) A standard protocol developed by the ISO for software applications and communicating devices operating in synchronous environments. Defines operations at the link level of communications—for example, the format of data frames exchanged between modems over a phone line.

head A small electromagnetic device inside a drive that reads, records, and erases data on the media.

head actuator The device that moves read/write heads across a disk drive's platters. Most drives use a stepper-motor or voice-coil actuator.

head crash A (usually) rare occurrence in which a read/write head strikes a platter surface with sufficient force to damage the magnetic medium.

head parking A procedure in which a disk drive's read/write heads are moved to an unused track so they will not damage data in the event of a head crash or other failure.

head seek The movement of a drive's read/write heads to a particular track.

heatsink A mass of metal attached to a chip carrier or socket for the purpose of dissipating heat. Some heatsinks are passive (relying on existing air currents only), but most heatsinks on processors are active (including a fan). Many video card accelerator chips and motherboard North Bridge chips are also fitted with heatsinks today.

helical scan A type of recording technology that has vastly increased the capacity of tape drives. Invented for use in broadcast systems and now used in VCRs. Conventional longitudinal recording records a track of data straight across the width of a single-track tape. Helical scan recording packs more data on the tape by positioning the tape at an angle to the recording heads. The heads spin to record diagonal stripes of information on the tape. Helical scan is used by DAT/DDS, Exabyte, and AIT drives.

hexadecimal number A number encoded in base-16, such that digits include the letters A–F and the numerals 0–9 (for example, 8BF3, which equals 35,827 in base-10).

hidden file A file not displayed in DOS directory listings because the file's attribute byte holds a special setting.

high-definition television (HDTV) Video formats offering greater visual accuracy (or resolution) than current NTSC, PAL, or SECAM broadcast standards. HDTV formats generally range in resolution from 655 to 2,125 scanning lines, having an aspect ratio of 5:3 (or 1.67:1) and a video bandwidth of 30MHz–50MHz (5+ times greater than the NTSC standard). Digital HDTV has a bandwidth of 300MHz. HDTV is subjectively comparable to 35mm film.

high density (HD) An indication of the storage capacity of a floppy drive or disk, in which 15 or 18 sectors per track are recorded using MFM encoding.

high-level formatting Formatting performed by the DOS FORMAT program. Among other things, it creates the root directory and FATs.

High Sierra format A standard format for placing files and directories on CD-ROMs, proposed by an ad hoc committee of computer vendors, software developers, and CD-ROM system integrators. (Work on the format proposal began at the High Sierra Hotel in Lake Tahoe, Nevada.) A revised version of the format was adopted by the ISO as ISO 9660. Use the ISO 9660 format to create cross-platform CD-R recordings.

history file A file created by utility software to keep track of earlier use of the software. Many backup programs, for example, keep history files describing earlier backup sessions.

hit ratio In describing the efficiency of a disk or memory cache, the hit ratio is the ratio of the number of times the data is found in the cache to the total number of data requests. 1:1 is a perfect hit ratio, meaning that every data request was found in the cache. The closer to 1:1 the ratio is, the more efficient the cache.

HMA (high memory area) The first 64KB of extended memory, which typically is controlled by the HIMEM.SYS device driver. Real-mode programs can be loaded into the HMA to conserve conventional memory. Normally, DOS 5.0 and later use the HMA exclusively to reduce the DOS conventional memory footprint.

HomePNA A home networking standard using existing home or office telephone wiring to obtain speeds up to 11Mbps.

HomeRF A wireless home network using radio waves to obtain speeds up to 11Mbps.

horizontal scan rate In monitors, the speed at which the electron beam moves laterally across the screen. It's normally expressed as a frequency; typical monitors range from 31.5KHz to 90KHz, with the higher frequencies being more desirable.

host The main device when two or more devices are connected. When two or more systems are connected, the system that contains the data is typically called the host, whereas the other is called the guest or user.

hotfix A software patch for a Microsoft application or operating system. Hotfixes can be downloaded individually from the Windows Update Web site or as a service pack. Microsoft also calls them quick fix engineering (QFE) files.

HPT (high-pressure tin) A PLCC socket that promotes high forces between socket contacts and PLCC contacts for a good connection.

HST (High-Speed Technology) The now-obsolete U.S. Robotics proprietary high-speed modem-signaling scheme, developed as an interim protocol until the V.32 protocol could be implemented in a cost-effective manner.

HTML (Hypertext Markup Language) A language used to describe and format plain-text files on the Web. HTML is based on pairs of tags that enable the user to mix graphics with text, change the appearance of text, and create hypertext documents with links to other documents. See also *DHTML*.

HTTP (Hypertext Transfer Protocol) The protocol that describes the rules a browser and server use to communicate over the World Wide Web. HTTP allows a Web browser to request HTML documents from a Web server. See also *hypertext*.

hub A common connection point for multiple devices in a network. A hub contains a number of ports to connect several segments of a LAN together. When a packet arrives at one of the ports on the hub, it is copied to all the other ports so all the segments of the LAN can see all the packets. A hub can be passive, intelligent (allowing remote management, including traffic monitoring and port configuration), or switching. A switching hub is also called a switch. See also *switch*.

Huffman coding A technique that minimizes the average number of bytes required to represent the characters in a text. Huffman coding works for a given character distribution by assigning short codes to frequently occurring characters and longer codes to infrequently occurring characters.

hybrid fiber coaxial (HFC) A network (such as that used by digital cable TV and two-way cable modems) that uses fiber-optic cabling for its backbone with coaxial cable connections to each individual computer or TV.

hypertext A technology that enables quick and easy navigation between and within large documents. Hypertext links are pointers to other sections within the same document; other documents; or other resources, such as FTP sites, images, or sounds.

HyperTransport AMD's high-speed technology for connecting the North Bridge and South Bridge or equivalent chips on a motherboard. HyperTransport runs at six times the speed of the PCI bus (800MBps versus 133MBps for PCI). The original name was Lightning Data Transport (LDT). Several chipset makers, including AMD and NVIDIA, use HyperTransport.

Hz An abbreviation for hertz—a frequency measurement unit used internationally to indicate one cycle per second.

i.Link Sony's term for IEEE 1394/FireWire port. See also *FireWire*.

I/O (input/output) A circuit path that enables independent communication between the processor and external devices.

I/O port (input/output port) Used to communicate to and from another device, such as a printer or disk.

IA-64 Intel's 64-bit processor architecture, first used in the Itanium processor for servers.

`IBMBIO.COM` One of the DOS system files required to boot the machine in older versions of PC-DOS (IBM's version of MS-DOS). The first file loaded from disk during the boot, it contains extensions to the ROM BIOS.

`IBMDOS.COM` One of the DOS system files required to boot the machine in older versions

of PC-DOS (IBM's version of MS-DOS). Contains the primary DOS routines. Loaded by `IBMBIO.COM`, it in turn loads `COMMAND.COM`.

IC (integrated circuit) A complete electronic circuit contained on a single chip. It can consist of only a few or thousands of transistors, capacitors, diodes, or resistors, and it generally is classified according to the complexity of the circuitry and the approximate number of circuits on the chip. SSI (small-scale integration) equals 2–10 circuits; MSI (medium-scale integration) equals 10–100 circuits. LSI (large-scale integration) equals 100–1,000 circuits, and VLSI (very-large-scale integration) equals 1,000–10,000 circuits. Finally, ULSI (ultra-large-scale integration) equals more than 10,000 circuits.

IDE (Integrated Drive Electronics) Describes a hard disk with the disk controller circuitry integrated within it. The first IDE drives commonly were called hard cards. Also refers to the ATA interface standard—the standard for attaching hard disk drives to ISA bus IBM-compatible computers. IDE drives typically operate as though they are standard ST-506/412 drives. See also *ATA*.

IEEE 802.3 See *10BASE-2*.

IEEE 802.11 family A family of wireless network standards commonly known as wireless Ethernet, the most popular of which include 802.11a (54Mbps using 5GHz signaling) and 802.11b (11Mbps using 2.4GHz signaling). 802.11b is frequently called Wi-Fi. See also *Wi-Fi*.

IEEE 1284 A series of standards for parallel ports. IEEE 1284 includes EPP and ECP configurations as well as the older bidirectional and 4-bit compatible parallel port modes. Printer cables that can work with all modes are referred to as IEEE 1284-compliant cables. See also *EPP* and *ECP*.

IEEE 1394 See *FireWire*.

illegal operation A command sent to Windows or the processor that can't be performed. Illegal operations can be triggered by software bugs or conflicts between programs in memory; although the name is reminiscent of a penalty in football, an illegal operation is hardly ever caused by the computer user. In most cases, you can continue to work and might even be able to restart the program without rebooting.

impedance The total opposition a circuit offers to the flow of alternating current, measured in ohms.

incremental backup A backup of all the files that have changed since the last backup.

inductive A property in which energy can be transferred from one device to another via the magnetic field generated by the device, even though no direct electrical connection is established between the two.

.INF file A Windows driver and device information file used to install new drivers or services.

ingot See *boule*.

initiator A device attached to the SCSI bus that sends a command to another device (the target) on the SCSI bus. The SCSI host adapter plugged into the system bus is an example of a SCSI initiator.

inkjet printer A type of printer that sprays one or more colors of ink on the paper; it can produce output with quality approaching that of a laser printer at a lower cost.

input Data sent to the computer from the keyboard, the telephone, a video camera, another computer, paddles, joysticks, and so on.

InstallShield A popular program used to create installation and uninstallation routines for Windows–based programs.

instruction Program step that tells the computer what to do for a single operation.

integrated circuit See *IC*.

interface A communications device or protocol that enables one device to communicate with another. Matches the output of one device to the input of the other device.

interlacing A method of scanning alternate lines of pixels on a display screen. The odd lines are scanned first from top to bottom and left to right. The electron gun goes back to the top and makes a second pass, scanning the even lines. Interlacing requires two scan passes to construct a single image. Because of this additional scanning, interlaced screens often seem to flicker unless a long-persistence phosphor is used in the display. Interlaced monitors were used with the IBM 8514/A display card but are now obsolete for desktop computers.

interleave ratio The number of sectors that pass beneath the read/write heads before the "next" numbered sector arrives. When the interleave ratio is 3:1, for example, a sector is read, two pass by, and then the next is read. A proper interleave ratio, laid down during low-level formatting, enables the disk to transfer information without excessive revolutions due to missed sectors. All modern IDE and SCSI drives have a 1:1 interleave ratio.

interleaved memory The process of alternating access between two banks of memory to overlap accesses, thus speeding up data retrieval. Systems that require only one memory module per bank to operate can work more quickly when two are installed if the system supports interleaved memory.

internal command In DOS, a command contained in `COMMAND.COM` so that no other file must be loaded to perform the command. `DIR` and `COPY` are two examples of internal commands.

internal device A peripheral device installed inside the main system case in either an expansion slot or a drive bay.

internal drive A disk or tape drive mounted inside one of a computer's disk drive bays (or a hard disk card, which is installed in one of the computer's slots).

Internet A computer network that joins many government, university, and private computers together over phone lines. The Internet traces its origins to a network set up in 1969 by the Department of Defense. You can connect to the Internet through many online services, such as CompuServe and America Online, or you can connect through local Internet service providers (ISPs). Internet computers use the TCP/IP communications protocol. Several million hosts exist on the Internet; a host is a mainframe, mini, or workstation that directly supports the Internet protocol (the IP in TCP/IP).

Internet Explorer (IE) Microsoft's line of Web browsers for Windows and Macintosh computers. Most Web sites are optimized to display best on systems running recent versions of IE.

interpreter A program for a high-level language that translates and executes the program at the same time. The program statements that are interpreted remain in their original source language, the way the programmer wrote them—that is, the program does not need to be compiled before execution. Interpreted programs run more slowly than compiled programs and always must be run with the interpreter loaded in memory.

interrupt A suspension of a process, such as the execution of a computer program, caused by an event external to that process and performed in such a way that the process can be resumed. An interrupt can be caused by internal or external conditions, such as a signal indicating that a device or program has completed a transfer of data. Hardware interrupts (also called IRQs) are used by devices, whereas software interrupts are used by programs. See also *IRQ*.

interrupt vector A pointer in a table that gives the location of a set of instructions the computer should execute when a particular interrupt occurs.

`IO.SYS` One of the DOS/Windows 9x system files required to boot the machine. The first file loaded from disk during the boot, it contains extensions to the ROM BIOS.

IP address An identifier for a computer or device on a TCP/IP network. The format of an IP address is a 32-bit numeric address written as four numbers separated by periods, in

which each number can be 0–255. The TCP/IP protocol routes messages based on the IP address of the destination.

IPv6 A new version of the IP protocol that expands the range of IP addresses from 32 bits to 128 bits, which relieves the strain on the current universe of IP addresses. IPv6 is backward compatible with IPv4 to allow its gradual adoption.

IPX (internetwork packet exchange) Novell NetWare's native LAN communications protocol (primarily in versions 4.x and earlier) used to move data between server and/or workstation programs running on different network nodes. IPX packets are encapsulated and carried by the packets used in Ethernet and the similar frames used in Token-Ring networks.

IrDA An infrared communications standard established by the Infrared Data Association in 1993. IrDA is currently used primarily for data transfer between portable computers or to allow portable computers to print to a printer with an IrDA port.

IRQ (interrupt request) Physical connections between external hardware devices and the interrupt controllers. When a device such as a floppy controller or a printer needs the attention of the CPU, an IRQ line is used to get the attention of the system to perform a task. On PC and XT IBM-compatible systems, eight IRQ lines are included, numbered IRQ0–IRQ7. On the AT and PS/2 systems, 16 IRQ lines are numbered IRQ0–IRQ15. IRQ lines must be used by only a single adapter in the ISA bus systems, but Micro Channel Architecture (MCA) adapters and most PCI-based systems can share interrupts. IRQ sharing with modern systems requires a system with PCI cards and Windows 95B or above. Windows 2000/XP are better at sharing IRQs than Windows 9x/Me.

ISA (Industry Standard Architecture) The bus architecture introduced as an 8-bit bus with the original IBM PC in 1981 and later expanded to 16 bits with the IBM PC/AT in 1984. ISA slots are occasionally found in PC systems today, but the latest chipsets have eliminated them.

ISA bus clock Clock that normally operates the ISA bus at 8.33MHz.

ISDN (Integrated Services Digital Network) An international telecommunications standard that enables a communications channel to carry digital data simultaneously with voice and video information.

ISO (International Standards Organization) The ISO, based in Paris, develops standards for international and national data communications. The U.S. representative to the ISO is the American National Standards Institute (ANSI). See also *High Sierra format*.

ISO 9660 An international standard that defines file systems for CD-ROM discs, independent of the operating system. ISO (International Standards Organization) 9660 has two levels. Level one provides for DOS file system compatibility, whereas level two allows filenames of up to 32 characters. See also *High Sierra format*.

ISP (Internet service provider) A company that provides Internet access to computer users. Most ISPs originally provided dialup analog modem service only, but many ISPs now provide various types of broadband support for DSL, cable modem, or fixed wireless Internet devices. Some ISPs, such as America Online (AOL), also provide proprietary content.

Itanium An Intel eighth-generation processor, codenamed Merced, it is the first 64-bit instruction PC processor from Intel. It features a new Explicitly Parallel Instruction Computing (EPIC) architecture for more performance when running optimized code. Also, it features internal L1/L2 and L3 error correcting code (ECC) caches to improve throughput and reliability. It was designed initially for the server or high-end workstation market.

ITU (International Telecommunications Union) Formerly called CCITT. An international committee organized by the United Nations to set international communications recommendations—which frequently are adopted as standards—and to develop interface, modem, and data network

recommendations. The Bell 212A standard for 1,200bps communication in North America, for example, is observed internationally as CCITT V.22. For 2,400bps communication, most U.S. manufacturers observe V.22bis, whereas V.32, V.32bis, V34, and V34+ are standards for 9,600bps, 14,400bps, 28,800bps, and 33,600bps, respectively. The V.90 standard recently was defined for 56Kbps modems.

J-lead J-shaped leads on chip carriers, which can be surface-mounted on a PC board or plugged into a socket that then is mounted on a PC board, usually on .050" centers.

jabber An error condition on an Ethernet-based network in which a defective network card or outside interference is constantly sending data, preventing the rest of the network from working.

Java An object-oriented programming language and environment similar to C or C++. Java was developed by Sun Microsystems and is used to create network-based applications.

JavaScript A scripting language developed by Netscape for Web browsers. JavaScript can perform calculations and mouse rollovers, but it doesn't require the Web browser to download additional files, as with Java.

Jaz drive A proprietary type of removable media drive with a magnetic hard disk platter in a rigid plastic case. Developed by Iomega and currently available in 1GB and 2GB sizes.

JEDEC (Joint Electron Devices Engineering Council) A group that establishes standards for the electronics industry. JEDEC established the original PC66 SDRAM standard.

Joliet Microsoft extension of the ISO 9660 standard for recordable/rewriteable CDs. Joliet is designed for use with 32-bit Windows versions that support long filenames, but it supports file/folder names up to 128 bytes (128 European or 64 Unicode characters) only. Some very long folder/filenames might need to be truncated when stored on a Joliet-format CD.

joule The standard unit of electrical energy, it's frequently used to measure the effectiveness of surge suppressors.

joystick An input device generally used for game software, usually consisting of a central upright stick that controls horizontal and vertical motion and one or more buttons to control discrete events, such as firing guns. More complex models can resemble flight yokes and steering wheels or incorporate tactile feedback.

JPEG (Joint Photographic Experts Group) The international consortium of hardware, software, and publishing interests which—under the auspices of the ISO—has defined a universal standard for digital compression and decompression of still images for use in computer systems. JPEG compresses at about a 20:1 ratio before visible image degradation occurs. A lossy data compression standard that was originally designed for still images but also can compress real-time video (30 frames per second) and animation. Lossy compression permanently discards unnecessary data, resulting in some loss of precision. Files stored in the JPEG format have the extension .jpg or .jpeg.

Jscript Microsoft's equivalent to JavaScript. See also *JavaScript*.

jukebox A type of CD-ROM drive that enables several CD-ROM discs to be in the drive at the same time. The drive itself determines which disc is needed by the system and loads the discs into the reading mechanism as needed.

jumper block A small, plastic-covered metal clip that slips over two pins protruding from a circuit board. Sometimes also called a shunt. When in place, the jumper block connects the pins electrically and closes the circuit. By doing so, it connects the two terminals of a switch, turning it "on."

K6 The popular line of Socket 7 and Super Socket 7 processors developed by AMD. Members included the K6, K6-2, and K6-III.

K56flex A proprietary standard for 56Kbps modem transmissions developed by Rockwell and implemented in modems from a variety of

vendors. Superseded by the official V.90 standard for 56Kbps modems. See also *X2*, *V.90*, and *V.92*.

Kermit A protocol designed for transferring files between microcomputers and mainframes. Developed by Frank DaCruz and Bill Catchings at Columbia University (and named after the talking frog on *The Muppet Show*), Kermit is widely accepted in the academic world.

kernel Operating system core component.

key disk In software copy protection schemes popular during the 1980s, a distribution floppy disk that must be present in a floppy disk drive for an application program to run.

keyboard The primary input device for most computers, consisting of keys with letters of the alphabet, digits, punctuation, and function control keys.

keyboard macro A series of keystrokes automatically input when a single key is pressed.

keylock Physical locking mechanism to prevent internal access to the system unit or peripherals.

kilo A multiplier indicating one thousand (1,000) of some unit. Abbreviated as k or K. When used to indicate a number of bytes of memory storage, the multiplier definition changes to 1,024. One kilobit, for example, equals 1,000 bits, whereas one kilobyte equals 1,024 bytes.

kilobyte (KB) A unit of information storage equal to 1,024 bytes.

kludge An inelegant but workable solution for a software or hardware problem.

L1 cache (level one) A memory cache built into the CPU core of 486 and later generation processors. See also *cache* and *disk cache*.

L2 cache (level two) A second-level memory cache external to the processor core, usually larger and slower than L1. Normally found on the motherboards of 386, 486, and Pentium systems and inside the processor packages or modules in Pentium Pro and later Intel processors, AMD K6-III processors, and Athlon and Duron processors. Cartridge-based caches used in the Pentium II, early Celeron, Pentium III, and Athlon processors run faster than motherboard cache but at speeds up to only one-half the CPU speed. Modern Socket 370, Socket A, and other socket-based processors contain the L2 cache inside the CPU die, enabling the L2 cache to work at the full speed of the processor. See also *SEC*, *cache*, and *disk cache*.

LAN Local area network; a network contained within a building. Both home and office networks are considered LANs. Ethernet, Fast Ethernet, Gigabit Ethernet, and Wireless Ethernet are used in office LANs, whereas home LANs might use Ethernet, Fast Ethernet, HomePNA, HomeRF, or Wi-Fi Wireless Ethernet.

landing zone An unused track on a disk surface on which the read/write heads can land when power is shut off. The place a parking program or a drive with an autopark mechanism parks the heads.

LAPM (link-access procedure for modems) An error-control protocol incorporated in CCITT Recommendation V.42. Similar to the MNP and HST protocols, it uses cyclic redundancy checking (CRC) and retransmission of corrupted data (ARQ) to ensure data reliability.

laptop computer A computer system smaller than a briefcase but larger than a notebook that usually has a clamshell design in which the keyboard and display are on separate halves of the system, which are hinged together. These systems normally run on battery power. Many vendors use the terms notebook and laptop computer interchangeably.

large mode A translation scheme used by the Award BIOS to translate the cylinder, head, and sector specifications of an IDE drive to those usable by an enhanced BIOS. It doesn't produce the same translated values as LBA mode and is not recommended because it is not supported by other BIOS vendors.

large-scale integration See *IC*.

laser printer A type of printer that is a combination of an electrostatic copying machine and a computer printer. The output data from the computer is converted by an interface into a raster feed, similar to the impulses a TV picture tube receives. The impulses cause the laser beam to scan a small drum that carries a positive electrical charge. Where the laser hits, the drum is discharged. A toner, which also carries a positive charge, is then applied to the drum. This toner—a fine, black powder—sticks to only the areas of the drum that have been discharged electrically. As it rotates, the drum deposits the toner on a negatively charged sheet of paper. Another roller then heats and bonds the toner to the page. See also *LED printer*.

latency 1) The amount of time required for a disk drive to rotate half a revolution. Represents the average amount of time to locate a specific sector after the heads have arrived at a specific track. Latency is part of the average access time for a drive. 2) The initial setup time required for a memory transfer in DRAM to select the row and column addresses for the memory to be read/written.

LBA (logical block addressing) A method used with SCSI and IDE drives to translate the cylinder, head, and sector specifications of the drive to those usable by an enhanced BIOS. LBA is used with drives that are larger than 528MB and causes the BIOS to translate the drive's logical parameters to those usable by the system BIOS.

LCC (leadless chip carrier) A type of integrated circuit package that has input and output pads rather than leads on its perimeter.

LCD (liquid crystal display) A display that uses liquid crystal sealed between two pieces of polarized glass. The polarity of the liquid crystal is changed by an electric current to vary the amount of light that can pass through. Because LCD displays do not generate light, they depend on either the reflection of ambient light or backlighting the screen. The best type of LCD, the active-matrix or thin-film transistor (TFT) LCD, offers fast screen updates and true color capability.

LED (light-emitting diode) A semiconductor diode that emits light when a current is passed through it.

LED printer A printer that uses an LED instead of a laser beam to discharge the drum.

legacy port I/O ports used on systems before the development of the multipurpose USB port. Serial, parallel, keyboard, and PS/2 mouse ports are legacy ports.

LIF (low insertion force) A type of socket that requires only a minimum of force to insert a chip carrier.

light pen A handheld input device with a light-sensitive probe or stylus connected to the computer's graphics adapter board by a cable. Used for writing or sketching onscreen or as a pointing device for making selections. Unlike mice, it's not widely supported by software applications.

line voltage The AC voltage available at a standard wall outlet, nominally 110–120v.

linear tape-open (LTO) An open standard for tape backups whose first products were introduced in mid-2000. LTO was jointly developed by Seagate, IBM, and Hewlett-Packard. Ultrium format products have capacities of up to 100GB, whereas the faster Accelis products have capacities of up to 25GB.

lithium-ion A portable system battery type that is longer-lived than either NiCad or NiMH technologies, can't be overcharged, and holds a charge well when not in use. Lithium-ion batteries are also lighter weight than the NiCad and NiMH technologies. Because of these superior features, Li-ion batteries have come to be used in all but the very low end of the portable system market.

local area network (LAN) The connection of two or more computers, usually via a network adapter card or NIC.

local bus A generic term used to describe a bus directly attached to a processor that operates at the processor's speed and data-transfer width.

local echo A modem feature that enables the modem to send copies of keyboard commands and transmitted data to the screen. When the modem is in command mode (not online to another system), the local echo usually is invoked through an ATE1 command, which causes the modem to display the user's typed commands. When the modem is online to another system, the local echo is invoked by an ATF0 command, which causes the modem to display the data it transmits to the remote system.

logical drive A drive as named by a DOS drive specifier, such as C: or D:. Under DOS 3.3 or later, a single physical drive can act as several logical drives, each with its own specifier. A primary partition can contain only one logical drive; an extended partition can contain one or more logical drives. See also *extended partition* and *primary partition*.

logical unit number See *LUN*.

lossless compression A compression technique that preserves all the original information in an image or other data structures. PKZIP and Microsoft CAB files are popular applications of lossless compression.

lossy compression A compression technique that achieves optimal data reduction by discarding redundant and unnecessary information in an image. MP3, MPEG, and JPEG are popular examples of lossy compression.

lost clusters Clusters that have been marked accidentally as "unavailable" in the FAT even though they don't belong to any file listed in a directory. See also *cluster*.

low-level formatting Formatting that divides tracks into sectors on the platter surfaces. Places sector-identifying information before and after each sector and fills each sector with null data (usually hex F6). Specifies the sector interleave and marks defective tracks by placing invalid checksum figures in each sector on a defective track.

LPT port Line printer port, a common system abbreviation for a parallel printer port. Common LPT port numbers range from LPT1 to LPT3.

LPX A semiproprietary motherboard design used in many Low Profile or Slimline case systems. Because no formal standard exists, these typically are not interchangeable between vendors and are often difficult to find replacement parts for or upgrade.

luminance Measure of brightness usually used in specifying monitor brightness.

LUN (logical unit number) A number given to a device (a logical unit) attached to a SCSI physical unit and not directly to the SCSI bus. Although as many as eight logical units can be attached to a single physical unit, a single logical unit typically is a built-in part of a single physical unit. A SCSI hard disk, for example, has a built-in SCSI bus adapter that is assigned a physical unit number or SCSI ID, and the controller and drive portions of the hard disk are assigned a LUN (usually 0). See also *PUN*.

LZW (Lempel Zev Welch) A compression scheme used in the GIF and TIFF graphic formats, named after its co-creators, Abraham Lempel, Jacob Ziv, and Terry Welch.

MAC address Short for Media Access Control address, this is a unique hardware number assigned to network hardware, such as NICs and routers. The MAC address assigned to the WAN side of some broadband Internet routers can be changed to equal the MAC address of the NIC previously used to attach to a broadband device, such as a cable modem.

machine address A hexadecimal (hex) location in memory.

machine language Hexadecimal program code a computer can understand and execute. It can be output from the assembler or compiler.

macro A series of commands in an application that can be stored and played back on demand. Many applications from various vendors support Microsoft Visual Basic for Applications as their macro language.

macro virus A computer virus that uses a scripting language to infect Microsoft Word document templates or email systems.

magnetic domain A tiny segment of a track just large enough to hold one of the magnetic flux reversals that encode data on a disk surface.

magneto-optical recording An erasable optical disk recording technique that uses a laser beam to heat pits on the disk surface to the point at which a magnet can make flux changes.

magneto-resistive A technology originally developed by IBM and commonly used for the read element of a read/write head on a high-density magnetic disk. Based on the principle that the resistance to electricity changes in a material when brought into contact with a magnetic field, in this case, the read element material and the magnetic bit. Such drives use a magneto-resistive read sensor for reading and a standard inductive element for writing. A magneto-resistive read head is more sensitive to magnetic fields than inductive read heads. Giant magneto-resistive heads are an improved version that store more data in the same space.

mainframe A somewhat vague distinction that identifies any large computer system normally capable of supporting many users and programs simultaneously.

mask A photographic map of the circuits for a particular layer of a semiconductor chip used in manufacturing the chip.

master boot record (MBR) On hard disks, a one-sector-long record that contains the master boot program as well as the master partition table containing up to four partition entries. The master boot program reads the master partition table to determine which of the four entries is active (bootable) and then loads the first sector of that partition, called the volume boot record. The master boot program tests the volume boot record for a 55AAh signature at offset 510; if it's present, program execution is transferred to the volume boot sector, which typically contains a program designed to load the operating system files. The MBR is always the first physical sector of the disk, at Cylinder 0, Head 0, Sector 1. Also called master boot sector.

math coprocessor A processing chip designed to quickly handle complex arithmetic computations involving floating-point arithmetic, offloading these from the main processor. Originally contained in a separate coprocessor chip, starting with the 486 family of processors. Intel now has incorporated the math coprocessor into the main processors in what is called the floating-point unit.

MCA (Micro Channel Architecture) Developed by IBM for the PS/2 line of computers and introduced on April 2, 1987. Features include a 16- or 32-bit bus width and multiple master control. By allowing several processors to arbitrate for resources on a single bus, the MCA is optimized for multitasking, multiprocessor systems. Offers switchless configuration of adapters, which eliminates one of the biggest headaches of installing older adapters. MCA systems became obsolete after the development of the PCI bus.

MCGA (multicolor graphics array) A type of PC video display circuit introduced by IBM on April 2, 1987, which supports text and graphics. Text is supported at a maximum resolution of 80×25 characters in 16 colors with a character box of 8×16 pixels. Graphics are supported at a maximum resolution of 320×200 pixels in 256 (from a palette of 262,144) colors or 640×480 pixels in two colors. The MCGA outputs an analog signal with a horizontal scanning frequency of 31.5KHz and supports analog color or analog monochrome displays.

MCI (media control interface) A device-independent specification for controlling multimedia devices and files. MCI is a part of the multimedia extensions and offers a standard interface set of device control commands. MCI commands are used for audio recording and playback and animation playback. Device types include CD audio, digital audio tape players, scanners, MIDI sequencers, videotape players or recorders, and audio devices that play digitized waveform files.

MDA (monochrome display adapter; also, MGA—mono graphics adapter) A type of PC video display adapter introduced by IBM on August 12, 1981, that supports text

only. Text is supported at a maximum resolution of 80×25 characters in four colors with a character box of 9×14 pixels. Colors, in this case, indicate black, white, bright white, and underlined. Graphics modes are not supported. The MDA outputs a digital signal with a horizontal scanning frequency of 18.432KHz and supports TTL monochrome displays. The IBM MDA card also includes a parallel printer port.

mean time between failure See *MTBF*.

mean time to repair See *MTTR*.

mebi A multiplier indicating 1,048,576 of a unit of measurement.

mebibyte (Mi) A unit of information storage equal to 1,048,576 bytes (1,024×1,024 equals 1Mi). This value was previously called a binary megabyte. See also *megabyte* and *kilobyte*.

medium The magnetic coating or plating that covers a disk or tape.

mega A multiplier indicating one million (1,000,000) of some unit. Abbreviated as m or M. Traditionally, mega has also been defined as 1,048,576 (1,024 kilobytes, where kilobyte equals 1,024) in applications such as memory sizing or disk storage (as defined by many BIOSes and by FDISK and other disk preparation programs). The term mebi is now used for 1,048,576. See also *mebi*.

megabyte (MB) A unit of information storage equal to 1,000,000 bytes. Also called a decimal megabyte. The value 1,048,576 bytes has been called a binary megabyte but is now known as a mebibyte. See also *mebibyte*.

megapixel A unit of digital camera resolution equal to approximately 1,000,000 pixels. A one-megapixel camera has a resolution of approximately 1,152×864; a two-megapixel camera has a resolution of approximately 1,760×1,168. Finally, a three-megapixel camera has a resolution of approximately 2,160×1,440. One-megapixel or lower-resolution cameras are suitable for 4"×6" or smaller snapshots only, whereas two-megapixel cameras produce excellent 5"×7" enlargements and acceptable 8"×10" enlargements. Three-megapixel or higher-resolution cameras produce excellent 8"×10" and 11"×14" enlargements. The higher the megapixel rating, the more flash memory space is used by each picture and the longer it takes each picture to be recorded to flash memory.

memory Any component in a computer system that stores information for future use.

memory caching A service provided by extremely fast memory chips that keeps copies of the most recent memory accesses. When the CPU makes a subsequent access, the value is supplied by the fast memory rather than by the relatively slow system memory. L1 and L2 caches are memory caches found on most recent processors. See also *L1 cache* and *L2 cache*.

memory-resident program A program that remains in memory after it has been loaded, consuming memory that otherwise might be used by application software.

Memory Stick A Sony-developed flash memory device that's about the size of a stick of gum. It is used by digital cameras, camcorders, digital music players, and voice recorders—primarily those made by Sony.

menu software Utility software that makes a computer running DOS easier to use by replacing DOS commands with a series of menu selections.

MFM encoding (modified frequency modulation encoding) A method of encoding data on the surface of a disk. The coding of a bit of data varies by the coding of the preceding bit to preserve clocking information. Used only by floppy drives today because it stores less data than other types of encoding such as RLL. See also *RLL*.

MHz An abbreviation for megahertz, a unit of measurement indicating the frequency of one million cycles per second. One hertz (Hz) is equal to one cycle per second. Named after Heinrich R. Hertz, a German physicist who first detected electromagnetic waves in 1883.

MI/MIC (mode indicate/mode indicate common) Also called forced or manual originate. Provided for installations in which

equipment other than the modem does the dialing. In such installations, the modem operates in dumb mode (no auto-dial capability), yet must go off-hook in originate mode to connect with answering modems.

micro (μ) A prefix indicating one millionth (1/1,000,000 or .000001) of some unit.

micron A unit of measurement equaling one millionth of a meter. Often used in measuring the size of circuits in chip manufacturing processes. Current state-of-the-art chip fabrication builds chips with 0.13 to 0.15-micron circuits.

microprocessor A solid-state central processing unit much like a computer on a chip. An integrated circuit that accepts coded instructions for execution.

microsecond (μs) A unit of time equal to one millionth (1/1,000,000 or .000001) of a second.

MIDI (musical instrument digital interface) An interface and file format standard for connecting a musical instrument to a microcomputer and storing musical instrument data. Multiple musical instruments can be daisy-chained and played simultaneously with the help of the computer and related software. The various operations of the instruments can be captured, saved, edited, and played back. A MIDI file contains note information, timing (how long a note is held), volume, and instrument type for as many as 16 channels. Sequencer programs are used to control MIDI functions such as recording, playback, and editing. MIDI files store only note instructions and not actual sound data. MIDI files can be played back by virtually all sound cards, but old sound cards might use FM synthesis to imitate the musical instruments called for in the MIDI file. Recent sound cards use stored musical instrument samples for more realistic MIDI playback.

MII A Socket 7–compatible processor originally developed by Cyrix and now sold by VIA Technologies as the VIA Cyrix MII.

milli (m) A prefix indicating one thousandth (1/1,000 or .001) of some unit.

millisecond (ms) A unit of time equal to one thousandth (1/1,000 or .001) of a second.

MIME (Multipurpose Internet Mail Extensions) Allows Internet and email services to exchange binary files and select the proper program to open the file after it's received.

minitower A type of PC system case that is shorter than a full- or mid-sized tower. Most low-cost computers sold at retail stores use the minitower case combined with a Micro-ATX motherboard.

MIPS (million instructions per second) Refers to the average number of machine-language instructions a computer can perform or execute in one second. Because various processors can perform different functions in a single instruction, MIPS should be used only as a general measure of performance among various types of computers.

MMX An Intel processor enhancement that adds 57 new instructions designed to improve multimedia performance. MMX also implies a doubling of the internal L1 processor cache on Pentium MMX processors compared to non-MMX Pentium processors. Later processors also include MMX along with other multimedia instructions.

mnemonic An abbreviated name for something used in a manner similar to an acronym. Computer processor instructions are often abbreviated with a mnemonic, such as JMP (jump), CLR (clear), STO (store), and INIT (initialize). A mnemonic name for an instruction or an operation makes it easy to remember and convenient to use.

MNP (Microcom Networking Protocol) Asynchronous error-control and data-compression protocols developed by Microcom, Inc., and now in the public domain. They ensure error-free transmission through error detection (CRC) and retransmission of erred frames. MNP Levels 1–4 cover error control and have been incorporated into CCITT Recommendation V.42. MNP Level 5 includes data compression but is eclipsed in superiority by V.42bis—an international

standard that is more efficient. Most high-speed modems connect with MNP Level 5 if V.42bis is unavailable. MNP Level 10 provides error correction for impaired lines and adjusts to the fastest possible speed during connection. MNP Level 10EC is an improved version of MNP Level 10, adding more reliability and support for cellular phone hand-offs.

MO (magneto-optical) MO drives use both magnetic and optical storage properties. MO technology is erasable and recordable, as opposed to CD-ROM (read-only) and WORM (write-once) drives. MO uses laser and magnetic field technology to record and erase data.

mobile module (MMO) A type of processor packing from Intel for mobile computers consisting of a Pentium or newer processor mounted on a small daughterboard along with the processor voltage regulator, system's L2 cache memory, and North Bridge part of the motherboard chipset.

modem (modulator/demodulator) A device that converts electrical signals from a computer into an audio form transmittable over telephone lines, or vice versa. It modulates, or transforms, digital signals from a computer into the analog form that can be carried successfully on a phone line; it also demodulates signals received from the phone line back to digital signals before passing them to the receiving computer. To avoid confusion with other types of Internet connection devices such as cable modems, modems are often called analog modems or dialup modems.

modulation The process of modifying some characteristic of a carrier wave or signal so that it varies in step with the changes of another signal, thus carrying the information of the other signal.

module An assembly that contains a complete circuit or subcircuit.

monitor See *display*.

monochrome display adapter See *MDA*.

MOS (metal-oxide semiconductor) Refers to the three layers used in forming the gate structure of a field-effect transistor (FET). MOS circuits offer low-power dissipation and enable transistors to be jammed closely together before a critical heat problem arises. PMOS, the oldest type of MOS circuit, is a silicon-gate P-channel MOS process that uses currents made up of positive charges. NMOS is a silicon-gate N-channel MOS process that uses currents made up of negative charges and is at least twice as fast as PMOS. CMOS, complementary MOS, is nearly immune to noise, runs off almost any power supply, and is an extremely low-power circuit technique.

motherboard The main circuit board in the computer. Also called planar, system board, or backplane.

mouse An input device invented by Douglas Engelbart of Stanford Research Center in 1963 and popularized by Xerox in the 1970s. A mechanical mouse consists of a roller ball and a tracking mechanism on the underside that relays the mouse's horizontal and vertical position to the computer, allowing precise control of the pointer location onscreen. The top side features two or three buttons and possibly a small wheel used to select or click items onscreen. Old-style optical mice sold in the 1980s used a single optical sensor and a grid-marked pad as an alternative to the roller ball. The latest optical mice use two optical sensors and can be moved across virtually any non-mirrored surface.

MPC A trademarked abbreviation for Multimedia Personal Computer. The original MPC specification was developed by Tandy Corporation and Microsoft as the minimum platform capable of running multimedia software. In the summer of 1995, the MPC Marketing Council introduced an upgraded MPC 3 standard. The MPC 1 Specification defines the following minimum standard requirements: a 386SX or 486 CPU; 2MB RAM; 30MB hard disk; VGA video display; 8-bit digital audio subsystem; CD-ROM drive; and systems software compatible with the applications programming interfaces (APIs) of Microsoft Windows version 3.1 or later. The MPC 2 specification defines the following minimum standard requirements: 25MHz 486SX with 4MB RAM; 160MB hard disk; 16-bit

sound card; 65,536-color video display; double-speed CD-ROM drive; and systems software compatible with the APIs of Microsoft Windows version 3.1 or later. The MPC 3 Specification defines the following minimum standard requirements: 75MHz Pentium with 8MB RAM; 540MB hard disk; 16-bit sound card; 65,536-color video display; quad-speed CD-ROM drive; OM-1–compliant MPEG-1 video, and systems software compatible with the APIs of Microsoft Windows version 3.1 and DOS 6.0 or later. Virtually all computers sold since 1995 exceed MPC 3 standards.

MPEG (Motion Picture Experts Group) A working ISO committee that has defined standards for lossy digital compression and decompression of motion video/audio for use in computer systems. The MPEG-1 standard delivers decompression data at 1.2MB/sec–1.5MB/sec, enabling CD players to play full-motion color movies at 30 frames per second. MPEG-1 compresses at about a 50:1 ratio before image degradation occurs, but compression ratios as high as 200:1 are attainable. MPEG-2 extends to the higher data rates (2Mbps–15Mbps) necessary for signals delivered from remote sources (such as broadcast, cable, or satellite). MPEG-2 is designed to support a range of picture aspect ratios, including 4:3 and 16:9. MPEG compression produces about a 50% volume reduction in file size. MP3 (the audio layer portion of the MPEG-1 standard) provides a wide range of compression ratios and file sizes for digital music storage, making it the de facto standard for exchanging digital music through sites such as Napster and its many rivals. See also *lossy compression*.

MPR The Swedish government standard for maximum video terminal radiation. The current version is called MPR II.

`MSDOS.SYS` One of the DOS/Windows 9x system files required to boot the machine. Contains the primary DOS routines. Loaded by `IO.SYS`, it in turn loads `COMMAND.COM`.

MTBF (mean time between failure) A statistically derived measure of the probable time a device will continue to operate before a hardware failure occurs, usually given in hours. Because no standard technique exists for measuring MTBF, a device from one manufacturer can be significantly more or significantly less reliable than a device with the same MTBF rating from another manufacturer.

MTTR (mean time to repair) A measure of the probable time it will take a technician to service or repair a specific device, usually given in hours.

Multichannel Multipoint Distribution Service (MMDS) The most common form of so-called "wireless cable TV," MMDS is also used for two-way wireless Internet service. One of the leading MMDS technology manufacturers is Hybrid (`www.hybrid.com`).

multicolor graphics array See *MCGA*.

multimedia The integration of sound, graphic images, animation, motion video, and text in one environment on a computer. It is a set of hardware and software technologies that is rapidly changing and enhancing the computing environment.

multisession A term used in CD-ROM recording to describe a recording event. Multisession capabilities allow data recording on the disk at various times in several recording sessions. Kodak's Photo CD is an example of multisession CD-R technology. See also *session* (single or multisession).

multitask To run several programs simultaneously.

multithread To concurrently process more than one message by an application program. OS/2 and 32-bit versions of Windows are examples of multithreaded operating systems. Each program can start two or more threads, which carry out various interrelated tasks with less overhead than two separate programs would require.

multiuser system A system in which several computer terminals share the same central processing unit (CPU).

nano (n) A prefix indicating one billionth (1/1,000,000,000 or .000000001) of some unit.

nanosecond (ns) A unit of time equal to one billionth (1/1,000,000,000 or .000000001) of a second.

NetBEUI (NetBIOS Extended User Interface) A network protocol used primarily by Windows NT and Windows 9x and most suitable for small peer-to-peer networks. NetBEUI is not supported by Microsoft in Windows XP and above but can still be manually installed for use in troubleshooting computers.

NetBIOS (Network Basic Input/Output System) A commonly used network protocol originally developed by IBM and Sytek for PC local area networks. NetBIOS provides session and transport services (Layers 4 and 5 of the OSI model).

NetWare Novell's server-based network for large businesses. NetWare 5 and NetWare 6 are designed to work well with IP-based networks.

network A system in which several independent computers are linked to share data and peripherals, such as hard disks and printers.

network interface card (NIC) An adapter that connects a PC to a network.

Network Layer In the OSI reference model, the layer that switches and routes the packets as necessary to get them to their destinations. This layer is responsible for addressing and delivering message packets. See also *OSI*.

NiCad The oldest of the three battery technologies used in portable systems, nickel cadmium batteries are rarely used in portable systems today because of their shorter life and sensitivity to improper charging and discharging. See also *NiMH* and *lithium-ion*.

NiMH A battery technology used in portable systems. Nickel metal-hydride batteries have approximately a 30% longer life than NiCads, are less sensitive to the memory effect caused by improper charging and discharging, and do not use the environmentally dangerous substances found in NiCads. Newer lithium-ion (Li-ion) batteries are far superior. NiMH batteries can sometimes be used in place of NiCads.

NLX A new low-profile motherboard form factor standard that is basically an improved version of the semiproprietary LPX design. It's designed to accommodate larger processor and memory form factors and incorporate newer bus technologies, such as AGP and USB. Besides design improvements, it is fully standardized, which means you should be able to replace one NLX board with another from a different manufacturer—something that was not normally possible with LPX.

node A device on a network. Also any junction point at which two or more items meet.

noise Any unwanted disturbance in an electrical or mechanical system.

noninterlaced monitor A desirable monitor design in which the electron beam sweeps the screen in lines from top to bottom, one line after the other, completing the entire screen in one pass. Virtually all CRTs sold recently for desktop use are noninterlaced.

nonvolatile memory (NVRAM) Random-access memory whose data is retained when power is turned off. ROM/EPROM/EEPROM (flash) memory are examples of nonvolatile memory. Sometimes NVRAM is retained without any power whatsoever, as in EEPROM or flash memory devices. In other cases, the memory is maintained by a small battery. NVRAM that is battery maintained is sometimes also called CMOS memory (although CMOS RAM technically is volatile). CMOS NVRAM is used in IBM-compatible systems to store configuration information. True NVRAM often is used in intelligent modems to store a user-defined default configuration loaded into normal modem RAM at power-up.

nonvolatile RAM disk A RAM disk powered by a battery supply so that it continues to hold its data during a power outage.

North Bridge The Intel term for the main portion of the motherboard chipset that incorporates the interface between the processor and the rest of the motherboard. The North Bridge contains the cache, main memory, and AGP controllers, as well as the interface between the high-speed (normally 66MHz or

100MHz) processor bus and the 33MHz PCI (peripheral component interconnect) or 66MHz AGP (accelerated graphics port) buses. See also *chipset* and *South Bridge*.

notebook computer A very small personal computer approximately the size of a notebook.

NTSC The National Television Standards Committee, which governs the standard for television and video playback and recording in the United States. The NTSC was originally organized in 1941 when TV broadcasting first began on a wide scale in black and white, and the format was revised in 1953 for color. The NTSC format has 525 scan lines, a field frequency of 60Hz, a broadcast bandwidth of 4MHz, a line frequency of 15.75KHz, a frame frequency of 1/30 of a second, and a color subcarrier frequency of 3.58MHz. It is an interlaced signal, which means it scans every other line each time the screen is refreshed. The signal is generated as a composite of red, green, and blue signals for color and includes an FM frequency for audio and a signal for stereo. See also *PAL* and *SECAM*, which are incompatible systems used in Europe. NTSC is also called composite video.

null modem A serial cable wired so that two data terminal equipment (DTE) devices, such as personal computers, or two data communication equipment (DCE) devices, such as modems or mice, can be connected. Also sometimes called a modem-eliminator or a LapLink cable. To make a null-modem cable with DB-25 connectors, you wire these pins together: 1-1, 2-3, 3-2, 4-5, 5-4, 6-8-20, 20-8-6, and 7-7.

numeric coprocessor See *math coprocessor*.

NVRAM (nonvolatile random access memory) Memory that retains data without power. Flash memory and battery-backed CMOS RAM are examples of NVRAM.

object hierarchy Occurs in a graphical program when two or more objects are linked and one object's movement is dependent on the other object. This is known as a parent-child hierarchy. In an example using a human figure, the fingers would be child objects to the hand, which is a child object to the arm, which is a child to the shoulder, and so on. Object hierarchy provides much control for an animator in moving complex figures.

OC (optical carrier) rates Various data rates for optical fiber used in Internet backbones, based on the OC-1 rate of 51.84Mbps. Multiply the OC rate by 51.84Mbps to derive the data rate. For example, OC-12 is 622.08Mbps (51.84×12).

Occam's Razor Also spelled Ockham's Razor; popular name for the principle that the simplest explanation is usually the correct one—a very useful principle in computer troubleshooting.

OCR (optical character recognition) An information-processing technology that converts human-readable text into computer data. Usually a scanner is used to read the text on a page, and OCR software converts the images to characters. Advanced OCR programs, such as OmniPage, can also match fonts, re-create page layouts, and scan graphics into machine-readable form.

ODI (Open Data-link Interface) A device driver standard from Novell that enables multiple protocols to run on the same network adapter card. ODI adds functionality to Novell's NetWare and network computing environments by supporting multiple protocols and drivers.

OEM (original equipment manufacturer) Any manufacturer who sells its product to a reseller. Usually refers to the original manufacturer of a particular device or component. Most HP hard disks, for example, are made by Seagate Technologies, who is considered the OEM. OEM products often differ in features from retail products and can have very short warranty periods if purchased separately from their intended use.

OLE (object linking and embedding) An enhancement to the original Dynamic Data Exchange (DDE) protocol that enables the user to embed or link data created in one application to a document created in another

application and subsequently edit that data directly from the final document.

online fallback A feature that enables high-speed error-control modems to monitor line quality and fall back to the next lower speed if line quality degrades. Some modems fall forward as line quality improves.

open architecture A system design in which the specifications are made public to encourage third-party vendors to develop add-on products. The PC is a true open architecture system, but the Macintosh is proprietary.

operating system (OS) A collection of programs for operating the computer. Operating systems perform housekeeping tasks, such as input and output between the computer and peripherals and accepting and interpreting information from the keyboard. Windows XP and MacOS X are examples of popular OSes.

optical disk A disk that encodes data as a series of reflective pits that are read (and sometimes written) by a laser beam.

Orange Book The standards for recordable (CD-R) and rewriteable (CD-RW) compact discs.

originate mode A state in which the modem transmits at the predefined low frequency of the communications channel and receives at the high frequency. The transmit/receive frequencies are the reverse of the called modem, which is in answer mode. See also *answer mode*.

OS/2 An operating system originally developed through a joint effort by IBM and Microsoft Corporation and later by IBM alone. Originally released in 1987, OS/2 is a 32-bit operating system designed to run on computers using the Intel 386 or later microprocessors. The OS/2 Workplace Shell, an integral part of the system, is a graphical interface similar to Microsoft Windows and the Apple Macintosh system. OS/2 Warp 4 is the most recent one and is used primarily as a server or in back-office functions today.

OSI (Open Systems Interconnection) A reference model developed by the International Organization for Standardization (ISO) in the 1980s, the OSI model splits a computer's networking stack into seven discrete layers. Each layer provides specific services to the layers above and below it. From the top down, the Application Layer is responsible for program-to-program communication; the Presentation Layer manages data representation conversions. Next, the Session Layer is responsible for establishing and maintaining communications channels, and the Transport Layer is responsible for the integrity of data transmission. The Network Layer routes data from one node to another, the Data Link Layer is responsible for physically passing data from one node to another, and finally, the Physical Layer is responsible for moving data on and off the network media.

output Information processed by the computer or the act of sending that information to a mass storage device, such as a video display, printer, or modem.

overclocking The process of running a processor or video card at a speed faster than the officially marked speed by using a higher clock multiplier, faster bus speed, or faster core clock speed. Not recommended or endorsed by processor or video card manufacturers. See also *clock multiplier*.

OverDrive An Intel trademark name for its line of upgrade processors for 486, Pentium, and Pentium Pro systems. Although Intel no longer sells OverDrive processors, similar products are available from Evergreen Technologies and PowerLeap Products, Inc., for these processors plus Pentium II and Celeron-based systems.

overlay Part of a program loaded into memory only when it is required.

overrun A situation in which data moves from one device more quickly than a second device can accept it.

overscanning A technique used in consumer display products that extends the deflection of a CRT's electron beam beyond the physical boundaries of the screen to ensure that images always fill the display area.

overwrite To write data on top of existing data, thus erasing the existing data.

package A device that includes a chip mounted on a carrier and sealed.

packet A message sent over a network that contains data and a destination address.

packet writing A recording technique that sends data to a CD-R or CD-RW disc in multiple blocks, enabling normal writing processes in Windows Explorer to be used instead of a CD-mastering program. Compatible packet-reading software, such as Adaptec's DirectCD, must be used on systems that don't have a CD-R or CD-RW drive to enable the media to be read.

pairing Combining processor instructions for optimal execution on superscalar processors.

PAL 1) Phase Alternating Line system. Invented in 1961, a system of TV broadcasting used in England and other European countries (except France). PAL's image format is 4:3, 625 lines, 50Hz, and 4MHz video bandwidth with a total 8MHz of video channel width. With its 625-line picture delivered at 25 frames per second, PAL provides a better image and an improved color transmission over the NTSC system used in North America. As a consequence, PAL and NTSC video tapes aren't interchangeable. 2) Programmable array logic, a type of chip that has logic gates specified by a device programmer.

palmtop computer A computer system smaller than a notebook that is designed so it can be held in one hand while being operated by the other. Many are now called PDAs or personal digital assistants.

parallel A method of transferring data characters in which the bits travel down parallel electrical paths simultaneously—for example, eight paths for 8-bit characters. Data is stored in computers in parallel form but can be converted to serial form for certain operations.

parity A method of error checking in which an extra bit is sent to the receiving device to indicate whether an even or odd number of binary 1 bits was transmitted. The receiving unit compares the received information with this bit and can obtain a reasonable judgment about the validity of the character. The same type of parity (even or odd) must be used by two communicating computers, or both may omit parity. When parity is used, a parity bit is added to each transmitted character. The bit's value is 0 or 1, to make the total number of 1s in the character even or odd, depending on which type of parity is used. Parity checking isn't widely supported on recent systems, but memory with parity bits can be used as ECC memory on systems with ECC-compatible chipsets. See also *ECC*.

park program A program that executes a seek to the highest cylinder or just past the highest cylinder of a drive so the potential of data loss is minimized if the drive is moved. Park programs are not interchangeable between drives and are no longer required on most drives 40MB and above because these drives self-park their heads for safety.

partition A section of a hard disk devoted to a particular operating system. Most hard disks have only one partition, devoted to DOS. A hard disk can have as many as four partitions, each occupied by a different operating system. DOS v3.3 or later can occupy two of these four partitions. A boot manager enables you to select the partition occupied by the operating system you want to start if you have multiple operating systems installed in different partitions. See also *boot manager*.

Pascal A high-level programming language named for the French mathematician Blaise Pascal (1623–1662). Developed in the early 1970s by Niklaus Wirth for teaching programming and designed to support the concepts of structured programming.

passive matrix Another name for dual-scan, display-type LCDs.

PC Card (PCMCIA—Personal Computer Memory Card International Association) A credit card–sized expansion adapter for notebook and laptop PCs. PC Card is the official PCMCIA trademark; however, both PC Card and PCMCIA card are used to refer to these

standards. PCMCIA cards are removable modules that can hold numerous types of devices, including memory, modems, fax/modems, radio transceivers, network adapters, solid state disks, hard disks, and flash memory adapters.

PCI (Peripheral Component Interconnect) A standard bus specification initially developed by Intel that bypasses the standard ISA I/O bus and uses the system bus to increase the bus clock speed and take full advantage of the CPU's data path. The most common form of PCI is 32 bits wide running at 33MHz, but 66MHz and 64-bit wide versions of PCI are frequently used on servers.

PCL (Printer Control Language) Developed by Hewlett-Packard in 1984 as a language for the HP LaserJet printer. PCL is now the de facto industry standard for PC printing. PCL defines a standard set of commands, enabling applications to communicate with HP or HP-compatible printers and is supported by virtually all printer manufacturers. Various levels of PCL are supported by HP and other brands of laser and inkjet printers.

PCM (pulse code modulation) A technique for digitizing analog signals by sampling the signal and converting each sample into a binary number. Also stands for powertrain control module, which is what the computer in most modern automobiles is called.

PDA (personal digital assistant) A handheld, palm-sized computer that functions primarily as a personal organizer and can be combined with a cellular phone or pager. Leading examples include the Palm series, Windows–based PalmPCs, and the Handspring (which also runs the Palm OS).

PDF (portable document format) Files with this extension can be read with the Adobe Acrobat Reader. See also *Acrobat*.

peer-to-peer A type of network in which any computer can act as both a server (by providing access to its resources to other computers) and a client (by accessing shared resources from other computers).

pel See *pixel*.

Pentium An Intel microprocessor with 32-bit registers, a 64-bit data bus, and a 32-bit address bus. The Pentium has a built-in L1 cache segmented into a separate 8KB cache for code and another 8KB cache for data. The Pentium includes an FPU or math coprocessor. It is backward compatible with the 486 and can operate in real, protected virtual, and virtual real modes. The MMX Pentium has a 16KB cache for code, has a 16KB cache for data, and adds the MMX instruction set.

Pentium 4 The first Intel seventh-generation processor, it's based on a new 32-bit microarchitecture that operates at higher clock speeds because of hyper pipelined technology, a rapid execution engine, a 400MHz system bus, and an execution trace cache. The 400MHz system bus is a quad-pumped bus running off a 100MHz system clock, making 3.2GB/sec data transfer rates possible. The advanced transfer cache is a 256KB, on-die Level 2 cache with increased bandwidth over previous microarchitectures. The floating-point and multimedia units have been improved by making the registers 128 bits wide and adding a separate register for data movement. Finally, SSE2 adds 144 new instructions for double-precision floating-point, SIMD integer, and memory management. The original version for Socket 423 was codenamed Willamette, whereas the latest Socket 478 version was codenamed Northwood.

Pentium II An Intel sixth-generation processor similar to the Pentium Pro but with MMX capabilities and SEC cartridge packaging technology. Includes L2 cache running at half-core speed.

Pentium III An Intel sixth-generation processor similar to the Pentium II but with SSE (Streaming SIMD Extensions) added. Later PIII models (codenamed Coppermine) include on-die L2 cache running at full core speed. It's available in both cartridge and chip package versions.

Pentium Pro An Intel sixth-generation (P6) processor with 32-bit registers, a 64-bit data bus, and a 36-bit address bus. The Pentium Pro has the same segmented Level 1 cache as the

Pentium but also includes a 256KB, 512KB, or 1MB of L2 cache on a separate die inside the processor package. The Pentium Pro includes an FPU or math coprocessor. It is backward compatible with the Pentium and can operate in real, protected, and virtual real modes. The Pentium Pro fits into Socket 8.

peripheral Any piece of equipment used in computer systems that is an attachment to the computer. Disk drives, terminals, and printers are all examples of peripherals.

persistence In a monitor, the quality of the phosphor chemical that indicates how long the glow caused by the electrons striking the phosphor will remain onscreen.

petabyte (P) A measure of disk capacity equaling 1,000,000,000,000,000 bytes.

PGA 1) Pin grid array. A chip package that has a large number of pins on the bottom designed for socket mounting. 2) Professional graphics adapter. A limited-production, high-resolution graphics card for XT and AT systems from IBM.

phosphor A layer of electroluminescent material applied to the inside face of a cathode-ray tube (CRT). When bombarded by electrons, the material fluoresces, and after the bombardment stops it phosphoresces.

phosphorescence The emission of light from a substance after the source of excitation has been removed.

Photo CD A technology developed by Eastman Kodak and Philips that stores photographic images on a CD-R recordable compact disc. Images stored on the Photo CD can have resolutions as high as 2,048×3,072 pixels. Up to 100 true-color images (24-bit color) can be stored on one disc. Photo CD images are created by scanning film and digitally recording the images on compact discs. The digitized images are indexed (given a 4-digit code), and thumbnails of each image on the disc are shown on the front of the case along with its index number. Multisession capability enables several rolls of film to be added to a single disc on different occasions.

photolithography The photographic process used in electronic chip manufacturing that creates transistors and circuit and signal pathways in semiconductors by depositing different layers of various materials on the chip.

photoresist A chemical used to coat a silicon wafer in the semiconductor manufacturing process that makes the silicon sensitive to light for photolithography.

physical drive A single disk drive. DOS defines logical drives, which are given a specifier, such as C: or D:. A single physical drive can be divided into multiple logical drives. Conversely, special software can span a single logical drive across two physical drives.

Physical Layer See *OSI*.

physical unit number See *PUN*.

Picture CD A simplified version of Photo CD that stores scanned images from a single roll of film on a CD-R disc. Images on Picture CDs, unlike those on Photo CDs, are stored in the industry-standard JPEG file format and can be opened with most photo-editing programs.

PIF (program information file) A file that contains information about a non-Windows application specifying optimum settings for running the program under Windows 3.x. These are called property sheets in 32-bit Windows.

pin 1) The lead on a connector, chip, module, or device. 2) Personal identification number. A personal password used for identification purposes.

pin compatible Chips having the same pinout functions. For example, a VIA C3 processor is pin compatible with an Intel Celeron (Socket 370 version).

pinout A listing of which pins have which functions on a chip, socket, slot, or other connector.

PIO mode (programmed input/output mode) The standard data transfer modes used by IDE drives that use the processor's registers for data transfer. This is in contrast with DMA modes, which transfer data directly

between main memory and the device. The slowest PIO mode is 0, and the fastest PIO mode is mode 4 (16.66MBps). Faster modes use Ultra DMA transfers. See also *Ultra DMA*.

pipeline A path for instructions or data to follow.

pixel A mnemonic term meaning picture element. Any of the tiny elements that form a picture on a video display screen. Also called a pel.

PKZIP The original ZIP-format compression/decompression program developed by the late Phil Katz. His company, PKWARE, continues to develop PKZIP for popular operating systems, including Windows.

planar board A term equivalent to motherboard, used by IBM in some of its literature.

plated media Hard disk platters plated with a form of thin metal film medium on which data is recorded.

platter A disk contained in a hard disk drive. Most drives have two or more platters, each with data recorded on both sides.

PLCC (plastic leaded-chip carrier) A chip-carrier package with J-leads around the perimeter of the package.

Plug and Play (PnP) A hardware and software specification developed by Intel that enables a PnP system and PnP adapter cards to automatically configure themselves. PnP cards are free from switches and jumpers and are configured via the PnP BIOS in the host system, or via supplied programs for non-PnP systems. PnP also allows the system to detect and configure external devices, such as monitors, modems, and devices attached to USB or IEEE-1394 ports. Windows 9x, Me, 2000, and XP all support PnP devices.

polling A communications technique that determines when a device is ready to send data. The system continually interrogates polled devices in a round-robin sequence. If a device has data to send, it sends back an acknowledgment and the transmission begins. Contrasts with interrupt-driven communications, in which the device generates a signal to interrupt the system when it has data to send. Polling enables two devices that would normally have an IRQ conflict to coexist because the IRQ is not used for flow control.

port Plug or socket that enables an external device, such as a printer, to be attached to the adapter card in the computer. Also a logical address used by a microprocessor for communication between it and various devices.

port address One of a system of addresses used by the computer to access devices such as disk drives or printer ports. You might need to specify an unused port address when installing any adapter boards in a system unit.

port replicator For mobile computers, a device that plugs into the laptop and provides all the ports for connecting external devices. The advantage of using a port replicator is that the external devices can be left connected to the replicator and the mobile computer connected to them all at once by connecting to the replicator, rather than connecting to each individual device. A port replicator differs from a docking station in that the latter can provide additional drive bays and expansion slots not found in port replicators. Traditionally, port replicators have plugged into a proprietary bus on the rear of a portable computer, but so-called universal models might attach to the PC Card (PCMCIA) slot or to a USB port.

portable computer A computer system smaller than a transportable system but larger than a laptop system. Very few systems in this form factor are sold today, but companies such as Dolch still produce them. Most portable systems conform to the lunchbox style popularized by Compaq or the briefcase style popularized by IBM, each with a fold-down (removable) keyboard and built-in display. These systems characteristically run on AC power and not on batteries, include several expansion slots, and can be as powerful as full desktop systems.

POS (Programmable Option Select) The Micro Channel Architecture's POS eliminates switches and jumpers from the system board and adapters by replacing them with programmable registers. Automatic configuration

routines store the POS data in a battery-powered CMOS memory for system configuration and operations. The configuration utilities rely on adapter description files (ADF) that contain the setup data for each card.

POST (power on self test) A series of tests run by the computer at power-on. Most computers scan and test many of their circuits and sound a beep from the internal speaker if this initial test indicates proper system performance.

PostScript A page-description language developed primarily by John Warnock of Adobe Systems for converting and moving data to the laser-printed page. Instead of using the standard method of transmitting graphics or character information to a printer and telling it where to place dots one by one on a page, PostScript provides a way for the laser printer to interpret mathematically a full page of shapes and curves. Adobe Acrobat converts PostScript output files into files that can be read by users with varying operating systems. See also *Acrobat*.

POTS (plain old telephone service) Standard analog telephone service.

power management Systems used initially in mobile computers (and now also used in desktop systems) to decrease power consumption by turning off or slowing down devices during periods of inactivity. See also *APM*.

power supply An electrical/electronic circuit that supplies all operating voltage and current to the computer system.

PPGA (plastic pin grid array) A chip-packaging form factor used by Intel as an alternative to traditional ceramic packaging.

PPP (Point-to-Point Protocol) A protocol that enables a computer to use the Internet with a standard telephone line and high-speed modem. PPP has largely replaced the Serial Line Internet Protocol (SLIP) because it supports line sharing and error detection.

precompensation A data write modification required by some older drives on the inner cylinders to compensate for the higher density of data on the (smaller) inner cylinders.

Presentation Layer See *OSI*.

primary partition An ordinary, single-volume bootable partition. See also *extended partition*.

printer A device that records information visually on paper or other material.

processor See *microprocessor*.

processor speed The clock rate at which a microprocessor processes data. A typical Pentium 4 processor, for example, operates at 2GHz (2 billion cycles per second).

program A set of instructions or steps telling the computer how to handle a problem or task.

PROM (programmable read-only memory) A type of memory chip that can be programmed to store information permanently—information that can't be erased. Also referred to as OTP for one-time programmable.

proprietary Anything invented by one company and that uses components available from only that one company. Especially applies to cases in which the inventing company goes to lengths to hide the specifications of the new invention or to prevent other manufacturers from making similar or compatible items. The opposite of standard or open architecture. Computers with nonstandard components that are available from only the original manufacturer, such as Apple Macintosh systems, are known as proprietary.

protected mode A mode available in all Intel and compatible processors except the first-generation 8086 and 8088. In this mode, memory addressing is extended beyond the 1MB limits of the 8088 and real mode and restricted protection levels can be set to trap software crashes and control the system.

protocol A system of rules and procedures governing communications between two or more devices. Protocols vary, but communicating devices must follow the same protocol to

exchange data. The data format, readiness to receive or send, error detection, and error correction are some of the operations that can be defined in protocols.

proxy server A computer that acts as a gateway between the computers on a network and the Internet and also provides page caching and optional content filtering and firewall services to the network. Some home network software solutions for Internet sharing, such as WinProxy, use a proxy server.

PS/2 mouse A mouse designed to plug into a dedicated mouse port (a round, 6-pin DIN connector) on the motherboard, rather than plugging into a serial port. The name comes from the fact that this port was first introduced on the IBM PS/2 systems.

PUN (physical unit number) A term used to describe a device attached directly to the SCSI bus. Also known as a SCSI ID. As many as eight SCSI devices can be attached to a single SCSI bus, and each must have a unique PUN or ID assigned from 7 to 0. Normally, the SCSI host adapter is assigned the highest-priority ID, which is 7. A bootable hard disk is assigned an ID of 0, and other nonbootable drives are assigned higher priorities.

QAM (quadrature amplitude modulation) A modulation technique used by high-speed modems that combines both phase and amplitude modulation. This technique enables multiple bits to be encoded in a single time interval.

QIC (Quarter-Inch Committee) An industry association that sets hardware and software standards for tape-backup units that use quarter-inch–wide tapes. QIC, QIC-Wide, Travan, and Travan NS drives are all based on QIC standards.

Quantum Formerly a major maker of hard disk drives and now a major maker of attached network storage devices. Quantum-brand disk drives are now sold and supported by Maxtor.

QWERTY keyboard The standard typewriter or computer keyboard, with the characters Q, W, E, R, T, and Y on the top row of alpha keys. Because of the haphazard placement of characters, this keyboard can hinder fast typing.

RAID (redundant array of independent or inexpensive disks) A storage unit that employs two or more drives in combination for fault tolerance and greater performance, used mostly in file server applications. Originally used only with SCSI drives and host adapters, many motherboards now feature IDE RAID implementations.

rails Plastic or metal strips attached to the sides of disk drives mounted in IBM ATs and compatibles so that the drives can slide into place. These rails fit into channels in the side of each disk drive bay position and might be held in position with screws or snap into place.

RAM (random-access memory) All memory accessible at any instant (randomly) by a microprocessor.

RAM disk A "phantom disk drive" in which a section of system memory (RAM) is set aside to hold data, just as though it were a number of disk sectors. To an operating system, a RAM disk looks and functions like any other drive.

RAMBUS Dynamic RAM See *RDRAM*.

RAMDAC (random-access memory digital-to-analog converter) A special type of DAC found on video cards. RAMDACs use a trio of DACs—one each for red, green, and yellow—to convert image data into a picture. RAMDACs were formerly separate chips but are now integrated into the 3D accelerator chips on most recent video cards.

random-access file A file in which all data elements (or records) are of equal length and written in the file end to end, without delimiting characters between. Any element (or record) in the file can be found directly by calculating the record's offset in the file.

random-access memory See *RAM*.

raster A pattern of horizontal scanning lines normally on a computer monitor. An electromagnetic field causes the beam of the monitor's tube to illuminate the correct dots to produce the required characters.

raster graphics A technique for representing a picture image as a matrix of dots. It is the digital counterpart of the analog method used in TV. Several raster graphics standards exist, including PCX, TIFF, BMP, JPEG, and GIF.

RCA jack Also called a phono connector. A plug and socket for a two-wire coaxial cable used to connect audio and video components. The plug is a 1/8" thick prong that sticks out 5/16" from the middle of a cylinder.

RDRAM (Rambus DRAM) A high-speed dynamic RAM technology developed by Rambus, Inc., which is supported by Intel's 1999 and later motherboard chipsets. RDRAM transfers data at 1GB/sec or faster, which is significantly faster than SDRAM and other technologies and which is capable of keeping up with future-generation high-speed processors. Memory modules with RDRAM chips are called RIMMs (Rambus inline memory modules). Rambus licenses its technology to other semiconductor companies, who manufacture the chips and RIMMs. RDRAMs are used by some of Intel's mid-range and high-end chipsets for the Pentium III and Pentium 4 desktop processors and their server counterparts.

read-only file A file whose attribute setting in the file's directory entry tells DOS not to allow software to write into or over the file.

read-only memory See *ROM*.

read/write head A tiny magnet that reads and writes data on a disk track.

real mode A mode available in all Intel 8086-compatible processors that enables compatibility with the original 8086. In this mode, memory addressing is limited to 1MB.

real-time The actual time in which a program or an event takes place. In computing, real-time refers to an operating mode under which data is received and processed and the results returned so quickly that the process appears instantaneous to the user. The term also is used to describe the process of simultaneous digitization and compression of audio and video information.

reboot The process of restarting a computer and reloading the operating system.

Red Book More commonly known as Compact Disc-Digital Audio (CD-DA), one of four compact disc standards. Red Book got its name from the color of the manual used to describe the CD-Audio specifications. The Red Book audio standard requires that digital audio be sampled at a 44.1KHz sample rate using 16 bits for each sample. This is the standard used by audio CDs and many CD-ROMs.

refresh cycle A cycle in which the computer accesses all memory locations stored by DRAM chips so that the information remains intact. DRAM chips must be accessed several times per second; otherwise, the information fades.

refresh rate Another term for the vertical scan frequency of monitors.

register Storage area in memory having a specified storage capacity—such as a bit, byte, or computer word—and intended for a special purpose.

Registry The system configuration files used by Windows 9x, Windows Me, Windows NT, Windows 2000, and Windows XP to store settings about installed hardware and drivers, user preferences, installed software, and other settings required to keep Windows running properly. Replaces the `WIN.INI` and `SYSTEM.INI` files from Windows 3.x. The Registry structure varies between Windows versions.

remote digital loopback A test that checks the phone link and a remote modem's transmitter and receiver. Data entered from the keyboard is transmitted from the initiating modem, received by the remote modem's receiver, looped through its transmitter, and returned to the local screen for verification.

remote echo A copy of the data received by the remote system, returned to the sending system, and displayed onscreen. A function of the remote system.

rendering Generating a 3D image that incorporates the simulation of lighting effects, such as shadows and reflection.

resolution 1) A reference to the size of the pixels used in graphics. In medium-resolution graphics, pixels are large. In high-resolution graphics, pixels are small. 2) A measure of the number of horizontal and vertical pixels that can be displayed by a video adapter and monitor.

reverse engineering The act of duplicating a hardware or software component by studying the functions of the component and designing a different one that has the same functions.

RFI (radio frequency interference) A high-frequency signal radiated by improperly shielded conductors, particularly when signal path lengths are comparable to or longer than the signal wavelengths. The FCC now regulates RFI in computer equipment sold in the U.S. under FCC Regulations, Part 15, Subpart J.

RGB (red green blue) A type of computer color display output signal comprised of separately controllable red, green, and blue signals; as opposed to composite video, in which signals are combined prior to output. RGB monitors offer much higher resolution and sharper pictures than composite monitors.

ribbon cable Flat cable with wires running in parallel, such as those used for internal IDE or SCSI.

Rich Text Format (RTF) A universal file format suitable for exchanging formatted text files between different word processing and page layout programs.

RIMM (Rambus inline memory module) A type of memory module made using RDRAM chips. See also *RDRAM*.

RISC (reduced instruction set computer) Differentiated from CISC, the complex instruction set computer. RISC processors have simple instruction sets requiring only one or a few execution cycles. These simple instructions can be used more effectively than CISC systems with appropriately designed software, resulting in faster operations. See also *CISC*.

RJ-11 The standard two-wire connector type used for single-line telephone connections.

RJ-14 The standard four-wire connector type used for two-line telephone connections.

RJ-45 A standard connector type used in networking with twisted-pair cabling. Resembles an RJ-11/14 telephone jack, but RJ-45 is larger with more wires.

RLL (run-length limited) A type of encoding that derives its name from the fact that the techniques used limit the distance (run length) between magnetic flux reversals on the disk platter. Several types of RLL encoding techniques exist, although only two are commonly used. (1,7) RLL encoding increases storage capacity by about 30% over MFM encoding and is most popular in the very highest capacity drives due to a better window margin, whereas (2,7) RLL encoding increases storage capacity by 50% over MFM encoding and is used in the majority of RLL implementations. Most IDE, ESDI, and SCSI hard disks use one of these forms of RLL encoding.

RMA number (return-merchandise authorization number) A number given to you by a vendor when you arrange to return an item for repairs. Used to track the item and the repair.

ROM (read-only memory) A type of memory that has values permanently or semipermanently burned in. These locations are used to hold important programs or data that must be available to the computer when the power initially is turned on.

ROM BIOS (read-only memory basic input/output system) A BIOS encoded in a form of read-only memory for protection.

root directory The main directory of any hard or floppy disk. It has a fixed size and location for a particular disk volume and can't be resized dynamically the way subdirectories can.

router A device that is used to connect various networks, intelligently routing information between them. It is used to internetwork similar and dissimilar networks and can select the most expedient route based on traffic load, line speeds, costs, and network failures. Routers use forwarding tables to determine

which packets should be forwarded between the connected networks. A cable or DSL modem is an example of a simple router that connects the Internet to your own network. Many routers include firewall capability to block suspect packets from being transmitted between networks.

routine Set of frequently used instructions. It can be considered as a subdivision of a program with two or more instructions that are related functionally.

RS-232 An interface introduced in August 1969 by the Electronic Industries Association. The RS-232 interface standard provides an electrical description for connecting peripheral devices to computers. Originally, RS-232 (serial) ports on computers used a 25-pin interface, but starting with the IBM AT, most use a 9-pin interface.

RTC (real-time clock) A battery-powered clock included on the motherboard of 286-class and newer computers. The contents of the RTC are read at startup time to provide the time display in the operating system's clock. It's often part of the NVRAM chip.

S.M.A.R.T. (self-monitoring analysis and reporting technology) An industry standard for advance reporting of imminent hard drive failure. When this feature is enabled in the BIOS and a S.M.A.R.T.-compliant hard drive is installed, detected problems can be reported to the computer. This enables the user to replace a drive before it fails. Programs such as Norton System Works and Norton Utilities are compatible with these status messages.

S/PDIF (Sony Philips Digital Interface) Provides digital I/O on high-end sound cards and multimedia-capable video cards. Might use either an RCA jack or optical jack; some devices support both types of S/PDIF connectors.

S-Video (Y/C) Type of video signal used in the Hi8 and S-VHS videotape formats in which the luminance and chrominance (Y/C) components are kept separate, providing greater control and quality of each image. S-video transmits luminance and color portions separately, thus avoiding the NTSC encoding process and its inevitable loss of picture quality.

scan codes The hexadecimal codes actually sent by the keyboard to the motherboard when a key is pressed.

scan lines The parallel lines across a video screen, along which the scanning spot travels in painting the video information that makes up a monitor picture. NTSC systems use 525 scan lines to a screen; PAL systems use 625.

ScanDisk The default Windows 9x/Me drive testing program; might be referred to as error checking in the Drive properties screen. Windows NT, Windows 2000, and Windows XP use CHKDSK to test drives.

scanner A device that reads an image and converts it into computer data.

scanning frequency A monitor measurement that specifies how often the image is refreshed. See also *vertical scan frequency*.

scratch disk A disk that contains no useful information and can be used as a test disk. IBM has a routine on the Advanced Diagnostics disks that creates a specially formatted scratch disk to be used for testing floppy drives.

SCSI (small computer system interface) A standard originally developed by Shugart Associates (then called SASI for Shugart Associates System Interface) and later approved by ANSI in 1986. SCSI-2 (now called SPI-2) was approved in 1994, and SCSI-3 (now called SPI-3) began the approval process in 1995. Ultra SCSI-4 (now called SPI-4) is currently in the development process. 8-bit (narrow) versions of SCSI typically use a 50-pin connector and permit multiple devices (up to 8 including the host) to be connected in daisy-chain fashion. Some low-cost narrow SCSI devices might use a 25-pin connector. Wide and Ultra Wide versions of SCSI use a 68-pin connector and can support up to 16 devices including the host.

SDLC (Synchronous Data Link Control) A protocol developed by IBM for software

applications and communicating devices operation in IBM's Systems Network Architecture (SNA). Defines operations at the link level of communications—for example, the format of data frames exchanged between modems over a phone line.

SDRAM (synchronous DRAM) RAM that runs at the same speed as the main system bus.

SEC (single edge contact) An Intel processor packaging design in which the processor and optional L2 cache chips are mounted on a small circuit board (much like an oversized memory SIMM), which might be sealed in a metal and plastic cartridge. The cartridge is then plugged into the motherboard through an edge connector called Slot 1 or Slot 2, which looks similar to an adapter card slot. Several variations to the SEC cartridge form factor exist: The single edge contact cartridge (SECC) has a cover and a thermal plate; the single edge contact cartridge 2 (SECC2) has a cover, but no thermal plate; and the single edge processor package (SEPP, which is used only with Celeron processors) has no cover or thermal plate. In implementations with no thermal plate, the heatsink is attached directly to the processor package or die.

SECAM Sequential Couleur A Mémoire (sequential color with memory), the French color TV system also adopted in Russia. The basis of operation is the sequential recording of primary colors in alternate lines. The image format is 4:3, 625 lines, 50Hz, and 6MHz video bandwidth with a total 8MHz of video channel width.

SECC (single edge contact cartridge) See *SEC*.

SECC2 (single edge contact cartridge 2) See *SEC*.

sector A section of one track defined with identification markings and an identification number. Most sectors hold 512 bytes of data.

security software Utility software that uses a system of passwords and other devices to restrict an individual's access to subdirectories and files.

seek time The amount of time required for a disk drive to move the heads across one third of the total number of cylinders. Represents the average time it takes to move the heads from one cylinder to another randomly selected cylinder. Seek time is a part of the average access time for a drive.

self-extracting file An archive file that contains its own extraction program. Open it in a file manager, such as Windows Explorer, to uncompress the files it contains. Because all types of files, including trojans, can be distributed as .exe files (the extension also used by self-extracting files), consider using a program such as WinZip to examine the contents of an .exe file before you open it.

semiconductor A substance, such as germanium or silicon, whose conductivity is poor at low temperatures but is improved by minute additions of certain substances or by the application of heat, light, or voltage. Depending on the temperature and pressure, a semiconductor can control a flow of electricity. Semiconductors are the basis of modern electronic-circuit technology.

SEPP (single edge processor package) See *SEC*.

sequencer A software program that controls MIDI file messages and keeps track of music timing. Because MIDI files store note instructions instead of actual sounds, a sequencer is needed to play, record, and edit MIDI sounds. Sequencer programs enable recording and playback of MIDI files by storing the instrument, note pitch (frequency), duration (in real-time) that each note is held, and loudness (amplitude) of each musical or sound-effect note.

sequential file A file in which varying-length data elements are recorded end to end, with delimiting characters placed between each element. To find a particular element, you must read the whole file up to that element.

serial The transfer of data characters one bit at a time, sequentially, using a single electrical path.

serial mouse A mouse designed to connect to a computer's serial port.

serial port An I/O connector used to connect to serial devices.

server A computer in a network that enables resources such as files and printers to be shared by multiple users.

servo The mechanism in a drive that enables the head positioner to adjust continuously so that it is precisely placed above a given cylinder in the drive.

servo data Magnetic markings written on disk platters to guide the read/write heads in drives that use voice-coil actuators.

session (single or multisession) A term used in CD-ROM recording to describe a recording event. In a single session, data is recorded on a CD-ROM and an index is created. If additional space is left on the disc, another session can be used to record additional files along with another index. Some older CD-ROM drives do not expect additional recording sessions and therefore are incapable of reading the additional session data on the disc. The advent of Kodak's Photo CD propelled the desire for multisession CD-ROM XA (extended architecture) drives.

Session Layer See *OSI*.

settling time The time required for read/write heads to stop vibrating after they have been moved to a new track.

shadow mask A thin screen full of holes that adheres to the inside of a color CRT. The electron beam is aimed through the holes in the mask onto the phosphor dots. See also *aperture grille*.

shadow RAM A copy of a system's slower-access ROM BIOS placed in faster-access RAM, usually during the startup or boot procedure. This setup enables the system to access BIOS code without the penalty of additional wait states required by the slower ROM chips. Also called shadow ROM or ROM shadowing.

shell The generic name of any user interface software. `COMMAND.COM` is the standard shell for DOS; 32-bit Windows uses the Windows Explorer as a graphical shell and either `COMMAND.COM` (Windows 9x/Me) or `CMD.EXE` (Windows NT/2000/XP) as the command-line shell.

shielded twisted-pair (STP) Unshielded twisted-pair (UTP) network cabling with a metal sheath or braid around it to reduce interference, usually used in Token-Ring networks.

shock rating A rating (usually expressed in G force units) of how much shock a disk drive can sustain without damage. Usually two specifications exist for a drive powered on or off.

signal-to-noise (S/N) ratio The strength of a video or an audio signal in relation to interference (noise). The higher the S/N ratio, the better the quality of the signal. The latest high-end sound cards have an S/N ratio of 100:1.

silicon The base material for computer chips. An element, silicon (symbol Si) is contained in the majority of rock and sand on earth and is the second most abundant element on the planet next to oxygen.

SIMD (single instruction multiple data) The term used to describe the MMX and SSE instructions added to the Intel processors. These instructions can process matrixes consisting of multiple data elements with only a single instruction, enabling more efficient processing of graphics and sound data.

SIMM (single inline memory module) An array of memory chips on a small PC board with a single row of I/O contacts. SIMMs commonly have 30 or 72 connectors.

single-ended An electrical signaling method in which a single line is referenced by a ground path common to other signals. In a single-ended bus intended for moderately long distances, commonly one ground line exists between groups of signal lines to provide some resistance to signal crosstalk. Single-ended signals require only one driver or receiver pin per signal, plus one ground pin per group of signals. Single-ended signals are vulnerable to common mode noise and crosstalk but are

much less expensive than differential signaling methods.

SIP (single inline package) A DIP-like package with only one row of leads.

skinny dip Twenty-four– and twenty-eight–position DIP devices with .300" row-to-row centerlines.

sleep See *suspend*.

SLIP (Serial Line Internet Protocol) An Internet protocol that is used to run the Internet Protocol (IP) over serial lines, such as telephone circuits. IP enables a packet to traverse multiple networks on the way to its final destination. Largely replaced by PPP. See also *PPP*.

slot A physical connector on a motherboard to hold an expansion card, SIMMs and DIMMs, or a processor card in place and make contact with the electrical connections.

Slot 1 The motherboard connector designed by Intel to accept its SEC cartridge processor design used by the Pentium II and early Celeron and Pentium III processors.

Slot 2 A motherboard connector for Pentium II and Pentium III Xeon processors intended mainly for file server applications. Slot 2 systems support up to four-way symmetric multiprocessing.

SMBIOS A BIOS that incorporates system management functions and reporting compatibility with the Desktop Management Interface (DMI).

SMPTE time code An 80-bit standardized edit time code adopted by SMPTE, the Society of Motion Picture and Television Engineers. The SMPTE time code is a standard used to identify individual video frames in the video-editing process. SMPTE time code controls such functions as play, record, rewind, and forward of video tapes. SMPTE time code displays video in terms of hours, minutes, seconds, and frames for accurate video editing.

snow A flurry of bright dots that can appear anywhere onscreen on a monitor.

SO-J (small outline J-lead) A small DIP package with J-shaped leads for surface mounting or socketing.

socket A receptacle, usually on a motherboard although sometimes also found on expansion cards, into which processors or chips can be plugged.

Socket 1–8 The Intel specifications for eight different sockets to accept various Intel processors in the 486, Pentium, and Pentium Pro families.

Socket 370 A 370-pin socket used by socketed versions of the Celeron and Pentium III and the VIA C3 processors.

Socket 423 The socket used by the initial versions of the Pentium 4.

Socket 462 See *Socket A*.

Socket 478 A 478-pin socket used by the Northwood versions of the Pentium 4.

Socket A A 462-pin socket used by socketed versions of the AMD Athlon and Duron.

SODIMM (small outline dual inline memory module) An industry-standard 144-pin memory module designed for use primarily in laptop and portable computers.

soft error An error in reading or writing data that occurs sporadically, usually because of a transient problem, such as a power fluctuation.

software A series of instructions loaded in the computer's memory that instructs the computer in how to accomplish a problem or task.

sound card An adapter card with sound-generating capabilities.

South Bridge The Intel term for the lower-speed component in the chipset that has always been a single individual chip. The South Bridge connects to the 33MHz PCI bus and contains the IDE interface ports and the interface to the 8MHz ISA bus (when present). It also typically contains the USB interface and even the CMOS RAM and real-time clock functions. The South Bridge contains all the

components that make up the ISA bus, including the interrupt and DMA controllers. See also *chipset* and *North Bridge*.

SPI (SCSI parallel interface) Alternative name for common SCSI standards. See also *SCSI*.

spindle The central post on which a disk drive's platters are mounted.

spindle count In notebook and laptop computers with interchangeable drives, spindle count refers to how many drives can be installed and used at the same time.

splitter Used in DSL and cable modem service to separate Internet signals from those used by the existing telephone (DSL) or cable TV service.

SRAM (static random access memory) A form of high-speed memory. SRAM chips do not require a refresh cycle like DRAM chips and can be made to operate at very high access speeds. SRAM chips are very expensive because they normally require six transistors per bit. This also makes the chips larger than conventional DRAM chips. SRAM is volatile, meaning it will lose data with no power. SRAMs are often used for cache memory.

SSE (streaming SIMD extensions) The name given by Intel for the 70 new MMX-type instructions added to the Pentium III processor when it was introduced. See also *MMX* and *SIMD*.

ST-506/412 A hard disk interface invented by Seagate Technology and introduced in 1980 with the ST-506 5MB hard drive. IDE drives emulate this disk interface.

stack An area of memory storage for temporary values that normally are read in the reverse order from which they are written. Also called last-in, first-out (LIFO).

stackable hub or switch A hub or switch that can be connected to another hub or switch to increase its capacity. The uplink port on the existing hub or switch is used to connect the new hub or switch.

stair-stepping Jagged raster representation of diagonals or curves; corrected by antialiasing.

standby Defines an optional operating state of minimal power reduction with the shortest recovery time.

standby power supply A backup power supply that quickly switches into operation during a power outage.

standoffs In a motherboard and case design, small nonconductive spacers (usually plastic or nylon) used to keep the underside of the motherboard from contacting the metallic case, therefore preventing short circuits of the motherboard.

start/stop bits The signaling bits attached to a character before and after the character is transmitted during asynchronous transmission.

starting cluster The number of the first cluster occupied by a file. Listed in the directory entry of every file.

stepper motor actuator An assembly that moves disk drive read/write heads across platters by a sequence of small partial turns of a stepper motor. Once common on low-cost hard disk drives of 40MB or less, stepper motor actuators are now confined to floppy disk drives.

stepping The code used to identify the revision of a processor. New masks are introduced to build each successive stepping, incorporating any changes necessary to fix known bugs in prior steppings.

storage Device or medium on or in which data can be entered or held and retrieved at a later time. Synonymous with memory.

streaming In tape backup, a condition in which data is transferred from the hard disk as quickly as the tape drive can record the data so the drive does not start and stop or waste tape.

string A sequence of characters.

subdirectory A directory listed in another directory. Subdirectories themselves exist as files.

subroutine A segment of a program that can be executed by a single call. Also called program module.

superscalar execution The capability of a processor to execute more than one instruction at a time.

surface mount Chip carriers and sockets designed to mount to the surface of a PC board.

surge protector A device in the power line that feeds the computer and provides protection against voltage spikes and other transients.

suspend Refers to a level of power management in which substantial power reduction is achieved by the display or other components. The components can have a longer recovery time from this state than from the standby state.

SVGA (Super VGA) Refers to a video adapter or monitor capable of 800×600 resolution.

SWEDAC (Swedish Board for Technical Accreditation) Regulatory agency establishing standards such as MPR1 and MPR2, which specify maximum values for both alternating electric fields and magnetic fields and provide monitor manufacturers with guidelines in creating low-emission monitors.

switch Also called a switching hub, it's a type of hub that reads the destination address of each packet and then forwards the packet to only the correct port, minimizing traffic on other parts of the network. Unlike a regular hub, which wastes network bandwidth by copying packets to all ports, a switch forwards packets to only their intended recipients, immediately reducing network traffic jams and improving overall efficiency for the entire network. Many switches also support full-duplex service, effectively doubling the speed of full-duplex network cards attached to the switch. See also *hub*.

SXGA (Super XGA) Refers to a video adapter or monitor capable of 1,280×1,024 or greater resolution.

synchronous communication A form of communication in which blocks of data are sent at strictly timed intervals. Because the timing is uniform, no start or stop bits are required. Compare with asynchronous communication. Some mainframes support only synchronous communication unless a synchronous adapter and appropriate software have been installed. See also *asynchronous communication*.

system crash A situation in which the computer freezes up and refuses to proceed without rebooting. Usually caused by faulty software, it's unlike a hard disk crash—no permanent physical damage occurs.

system files Files with the system attribute. Usually, the hidden files that are used to boot the operating system. The MS-DOS and Windows 9x system files include `IO.SYS` and `MSDOS.SYS`; the IBM DOS system files are `IBMBIO.COM` and `IBMDOS.COM`.

System Management Mode (SMM) Circuitry integrated into Intel processors that operates independently to control the processor's power use based on its activity level. It enables the user to specify time intervals after which the CPU will be powered down partially or fully and also supports the suspend/resume feature that enables instant power-on and power-off.

tape drive Any data storage drive that uses tape as the storage medium.

target A device attached to a SCSI bus that receives and processes commands sent from another device (the initiator) on the SCSI bus. A SCSI hard disk is an example of a target.

TCM (Trellis-coded modulation) An error-detection and correction technique employed by high-speed modems to enable higher-speed transmissions that are more resistant to line impairments.

TCO 1) Refers to the Swedish Confederation of Professional Employees, which has set stringent standards for devices that emit radiation. See also *MPR*. 2) Total cost of ownership. The cost of using a computer. It includes the cost of the hardware, software, and upgrades as

well as the cost of the in-house staff and consultants who provide training and technical support.

TCP (tape carrier package) A method of packaging processors for use in portable systems that reduces the size, power consumed, and heat generated by the chip. A processor in the TCP form factor is essentially a raw die encased in an oversized piece of polyamide film. The film is laminated with copper foil that is etched to form the leads that will connect the processor to the motherboard.

TCP/IP (Transmission Control Protocol/Internet Protocol) A set of protocols developed by the U.S. Department of Defense (DoD) to link dissimilar computers across many types of networks. This is the primary protocol used by the Internet.

TCP port number Logical port numbers used by TCP to communicate between computers—for example, Web browsing (`http://`) uses TCP port 80. POP3 email uses TCP port 110. Some firewalls require you to manually configure open TCP port numbers to allow certain processes and programs to work.

temporary backup A second copy of a work file, usually having the extension BAK. Created by application software so you easily can return to a previous version of your work.

temporary file A file temporarily (and usually invisibly) created by a program for its own use.

tera A multiplier indicating one trillion (1,000,000,000,000) of some unit. Abbreviated as t or T. A binary tera (now called a tebi) is 1,099,511,627,776.

terabyte (T) A unit of information storage equal to 1,000,000,000 bytes.

terminal A device whose keyboard and display are used for sending and receiving data over a communications link. Differs from a microcomputer in that it has no internal processing capabilities. Used to enter data into or retrieve processed data from a system or network.

terminal mode An operational mode required for microcomputers to transmit data. In terminal mode, the computer acts as though it were a standard terminal, such as a teletypewriter, rather than a data processor. Keyboard entries go directly to the modem, whether the entry is a modem command or data to be transmitted over the phone lines. Received data is output directly to the screen. The more popular communications software products control terminal mode and enable more complex operations, including file transmission and saving received files.

terminator Hardware or circuits that must be attached to or enabled at both ends of an electrical bus. Functions to prevent the reflection or echoing of signals that reach the ends of the bus and to ensure that the correct impedance load is placed on the driver circuits on the bus. Most commonly used with the SCSI bus and Thin Ethernet.

TFT (thin film transistor) The highest quality and brightest LCD color display type. A method for packaging one–four transistors per pixel within a flexible material that is the same size and shape as the LCD display, which enables the transistors for each pixel to lie directly behind the liquid crystal cells they control.

thick Ethernet See *10BASE-5*.

thin Ethernet See *10BASE-2*.

thin-film media Hard disk platters that have a thin film (usually three-millionths of an inch) of medium deposited on the aluminum substrate through a sputtering or plating process.

Thinnet See *10BASE-2*.

through-hole Chip carriers and sockets equipped with leads that extend through holes in a PC board.

throughput The amount of user data transmitted per second without the overhead of protocol information, such as start and stop bits or frame headers and trailers.

TIFF (tagged image file format) A way of storing and exchanging digital image data.

Developed by Aldus Corporation, Microsoft Corporation, and major scanner vendors to help link scanned images with the popular desktop publishing applications. Supports three main types of image data: black-and-white data, halftones or dithered data, and grayscale data. Compressed TIFF files are stored using lossless compression.

time code A frame-by-frame address code time reference recorded on the spare track of a videotape or inserted in the vertical blanking interval. The time code is an eight-digit number encoding time in hours, minutes, seconds, and video frames.

Token-Ring A type of local area network in which the workstations relay a packet of data called a token in a logical ring configuration. When a station wants to transmit, it takes possession of the token, attaches its data, and then frees the token after the data has made a complete circuit of the electrical ring. Transmits at speeds of 16Mbps. Because of the token-passing scheme, access to the network is controlled, unlike the slower 10BASE-X Ethernet system in which collisions of data can occur, which wastes time. The Token-Ring network uses shielded twisted-pair wiring, which is cheaper than the coaxial cable used by 10BASE-2 and 10BASE-5 Ethernet and ARCnet.

toner The ultrafine, colored, plastic powder used in laser printers, LED printers, and photocopiers to produce the image on paper.

tower A personal computer that normally sits on the floor and is mounted vertically rather than horizontally.

TPI (tracks per inch) Used as a measurement of magnetic track density. Standard 5 1/4" 360KB floppy disks have a density of 48TPI, and the 1.2MB disks have a 96TPI density. All 3 1/2" disks have a 135.4667TPI density, and hard disks can have densities greater than 3,000TPI.

track One of the many concentric circles that holds data on a disk surface. Consists of a single line of magnetic flux changes and is divided into some number of 512-byte sectors.

track density Expressed as tracks per inch (TPI); defines how many tracks are recorded in 1" of space measured radially from the center of the disk. Sometimes also called radial density.

track-to-track seek time The time required for read/write heads to move between adjacent tracks.

transistor A semiconductor device invented in 1947 at Bell Labs (released in 1948) that is used to amplify a signal or open and close a circuit. In digital computers, it functions as an electronic switch. It is reduced to microscopic size in modern digital integrated circuits containing 100 million or more individual transistors.

Transport Layer In the OSI reference model, when more than one packet is in process at any time, such as when a large file must be split into multiple packets for transmission, this is the layer that controls the sequencing of the message components and regulates inbound traffic flow. See also *OSI*.

transportable computer A computer system larger than a portable system and similar in size and shape to a portable sewing machine. Most transportables conform to a design similar to the original Compaq portable, with a built-in CRT display. These systems are characteristically very heavy and run on only AC power. Because of advances primarily in LCD and plasma-display technology, these systems are obsolete and have been replaced by portable systems.

troubleshooting The task of determining the cause of a problem.

true-color images Also called 24-bit color images because each pixel is represented by 24 bits of data, allowing for 16.7 million colors. The number of colors possible is based on the number of bits used to represent the color. If 8 bits are used, 256 possible color values (2^8) exist. To obtain 16.7 million colors, each of the primary colors (red, green, and blue) is represented by 8 bits per pixel, which enables 256 possible shades for each of the primary red, green, and blue colors or 256×256×256 = 16.7 million total colors.

TrueType An Apple/Microsoft developed scalable font technology designed to provide a high-performance alternative to PostScript Type 1 fonts. TrueType fonts are supported by both Windows and MacOS, but a particular TrueType font must either be made in both MacOS and Windows versions or support the cross-platform OpenType font format to be used on both platforms.

TSR (terminate-and-stay-resident) A program that remains in memory after being loaded. Because they remain in memory, TSR programs can be reactivated by a predefined keystroke sequence or other operation while another program is active. Usually called resident programs. TSR programs are often loaded from the `AUTOEXEC.BAT` file used at startup by DOS and Windows 9x.

TTL (transistor-to-transistor logic) Digital signals often are called TTL signals. A TTL display is a monitor that accepts digital input at standardized signal voltage levels.

TWAIN Imaging standard used to interface scanners and digital cameras to applications such as Photoshop and other image editors. TWAIN enables the user to scan or download pictures without exiting the image editing program.

TweakUI An unsupported software utility provided by Microsoft for 32-bit Windows users. TweakUI allows users to change the user interface and adjust Registry settings without manual Registry editing.

twisted pair A type of wire in which two small, insulated copper wires are wrapped or twisted around each other to minimize interference from other wires in the cable. Two types of twisted-pair cables are available: unshielded and shielded. Unshielded twisted-pair (UTP) wiring commonly is used in telephone cables and 10BASE-T, 100BASE-TX, and 1000BASE-T networking and provides little protection against interference. Shielded twisted-pair (STP) wiring is used in some networks or any application in which immunity from electrical interference is more important. Twisted-pair wire is much easier to work with than coaxial cable and is cheaper as well.

typematic The keyboard repeatedly sending the keypress code to the motherboard for a key that is held down. The delay before the code begins to repeat and the speed at which it repeats are user adjustable through `MODE` commands in DOS or the Windows Control Panel.

UART (Universal Asynchronous Receiver Transmitter) A chip device that controls the RS-232 serial port in a PC-compatible system. Originally developed by National Semiconductor, several UART versions are in PC-compatible systems: The 8250B is used in PC- and XT-class systems, and the 16450 and 16550 series are used in AT-class systems. The 16650 and higher UARTs are used for specialized high-speed serial communication cards.

UDF (Universal Disk Format) The disk format used by packet-writing software, such as Adaptec DirectCD. See also *packet writing*.

Ultra DMA (UDMA or Ultra ATA) A protocol for transferring data to an ATA interface hard drive. The Ultra DMA/33 protocol transfers data in burst mode at a rate of 33MBps, whereas the even faster Ultra DMA/66 protocol transfers at 66MBps. Ultra DMA/66 also requires the use of a special 80-conductor cable for signal integrity. This cable also is recommended for Ultra DMA/33 and is backward compatible with standard ATA/IDE cables. The fastest UDMA modes are Ultra DMA/100 (supported by most recent chipsets) and Ultra DMA/133 (introduced by Maxtor in 2001).

UltraXGA (UXGA) A screen resolution of 1,600×1,200.

UMB (upper memory block) A block of unused memory in the upper memory area (UMA), which is the 384KB region between 640KB and 1MB of memory space in the PC. BIOS chips and memory buffers on add-on cards must be configured to use empty areas of the UMB; otherwise, they will not work.

unformatted capacity The total number of bytes of data that can fit on a disk. The formatted capacity is lower because space is lost defining the boundaries between sectors. For example, some vendors have referred to the high-density 1.44MB floppy disk as a 2.0MB

disk (2.0MB is the unformatted capacity). However, because most media is preformatted today, this issue is fading away.

Unicode A worldwide standard for displaying, interchanging, and processing all types of language texts, including both those based on letters (such as Western European languages) and pictographs (such as Chinese, Japanese, and Korean).

uninterruptible power supply (UPS) A device that supplies power to the computer from batteries so power will not stop, even momentarily, during a power outage. The batteries are recharged constantly from a wall socket.

Universal Asynchronous Receiver Transmitter See *UART*.

unzipping The process of extracting one or more files from a PKZIP or WinZip-compatible archive file.

UPC (universal product code) A 10-digit computer-readable bar code used in labeling retail products. The code in the form of vertical bars includes a five-digit manufacturer identification number and a five-digit product code number.

update To modify information already contained in a file or program with current information.

upper memory area (UMA) The 384KB of memory between 640KB and 1MB. See also *UMB*.

URL (uniform resource locator) The primary naming scheme used to identify a particular site or file on the World Wide Web. URLs combine information about the protocol being used, the address of the site where the resource is located, the subdirectory location at the site, and the name of the particular file (or page) in question.

USB (universal serial bus) USB version 1.1 is a 12Mbps (1.5MBps) interface over a simple four-wire connection. The bus supports up to 127 devices and uses a tiered star topology built on expansion hubs that can reside in the PC, any USB peripheral, or even standalone hub boxes. USB 2.0, also called High-Speed USB, runs at 480Mbps and handles multiple devices better than USB 1.1.

utility A program that carries out routine procedures to make computer use easier.

UTP (unshielded twisted pair) A type of wire often used indoors to connect telephones or computer devices. Comes with two or four wires twisted inside a flexible plastic sheath or conduit and uses modular plugs and phone jacks.

V.21 An ITU standard for modem communications at 300bps. Modems made in the U.S. or Canada follow the Bell 103 standard but can be set to answer V.21 calls from overseas. The actual transmission rate is 300 baud and employs frequency shift keying (FSK) modulation, which encodes a single bit per baud.

V.22 An ITU standard for modem communications at 1,200bps, with an optional fallback to 600bps. V.22 is partially compatible with the Bell 212A standard observed in the U.S. and Canada. The actual transmission rate is 600 baud, using differential-phase shift keying (DPSK) to encode as much as 2 bits per baud.

V.22bis An ITU standard for modem communications at 2,400bps. Includes an automatic link-negotiation fallback to 1,200bps and compatibility with Bell 212A/V.22 modems. The actual transmission rate is 600 baud, using quadrature amplitude modulation (QAM) to encode as much as 4 bits per baud.

V.23 An ITU standard for modem communications at 1,200bps or 600bps with a 75bps back channel. Used in the United Kingdom for some videotext systems.

V.25 An ITU standard for modem communications that specifies an answer tone different from the Bell answer tone used in the U.S. and Canada. Most intelligent modems can be set with an ATB0 command so they use the V.25 2,100Hz tone when answering overseas calls.

V.32 An ITU standard for modem communications at 9,600bps and 4,800bps. V.32 modems fall back to 4,800bps when line quality is impaired and fall forward again to

9,600bps when line quality improves. The actual transmission rate is 2,400 baud using quadrature amplitude modulation (QAM) and optional trellis-coded modulation (TCM) to encode as much as 4 data bits per baud.

V.32bis An ITU standard that extends the standard V.32 connection range and supports 4,800bps; 7,200bps; 9,600bps; 12,000bps; and 14,400bps transmission rates. V.32bis modems fall back to the next lower speed when line quality is impaired, fall back further as necessary, and fall forward to the next higher speed when line quality improves. The actual transmission rate is 2,400 baud using quadrature amplitude modulation (QAM) and trellis-coded modulation (TCM) to encode as much as 6 data bits per baud.

V.32terbo A proprietary standard proposed by several modem manufacturers that will be cheaper to implement than the standard V.32 fast protocol but that will support transmission speeds of up to only 18,800bps. Because it is not an industry standard, it is not likely to have widespread industry support.

V.34 An ITU standard that extends the standard V.32bis connection range, supporting 28,800bps transmission rates as well as all the functions and rates of V.32bis. This was called V.32fast or V.fast while under development.

V.34+ An ITU standard that extends the standard V.34 connection range, supporting 33,600bps transmission rates as well as all the functions and rates of V.34.

V.42 An ITU standard for modem communications that defines a two-stage process of detection and negotiation for LAPM error control. Also supports MNP error-control protocol, Levels 1–4.

V.42bis An extension of CCITT V.42 that defines a specific data-compression scheme for use with V.42 and MNP error control.

V.44 ITU-T designation for a faster data-compression scheme than V.42bis. V.44 can compress data up to 6:1. V.44 is included on most V.92-compliant modems. See also *V.92*.

V.90 ITU-T designation for defining the standard for 56Kbps communication. Supersedes the proprietary X2 schemes from U.S. Robotics (3Com) and K56flex from Rockwell.

V.92 ITU-T designation for an improved version of the V.90 protocol. V.92 allows faster uploading (up to 48Kbps), faster connections, and optional modem-on-hold (enabling you to take calls while online). Most V.92 modems also support V.44 compression. See also *V.44*.

V-Link A VIA Technologies high-speed (266MBps) bus between the North Bridge and South Bridge chips in VIA chipsets, such as the P4X266 (for Pentium 4) and KT266/266A (for Athlon/Duron). V-Link is twice as fast as the PCI bus and provides a dedicated pathway for data transfer.

vaccine A type of program used to locate and eradicate virus code from infected programs or systems.

VCPI (virtual control program interface) A 386 and later processor memory management standard created by Phar Lap software in conjunction with other software developers. VCPI provides an interface between applications using DOS extenders and 386 memory managers.

vertical blanking interval (VBI) The top and bottom lines in the video field, in which frame numbers, picture stops, chapter stops, white flags, closed captions, and more can be encoded. These lines do not appear on the display screen but maintain image stability and enhance image access.

vertical scan frequency The rate at which the electron gun in a monitor scans or refreshes the entire screen each second.

very large scale integration See *IC*.

VESA (Video Electronics Standards Association) Founded in the late 1980s by NEC Home Electronics and eight other leading video board manufacturers with the main goal to standardize the electrical, timing, and programming issues surrounding 800×600 resolution video displays, commonly known as Super VGA. VESA has also developed the Video

Local Bus (VL-Bus) standard for connecting high-speed adapters directly to the local processor bus. The most recent VESA standards involve digital flat-panel displays and display identification.

VFAT (virtual file allocation table) A file system used in Windows for Workgroups and Windows 9x. VFAT provides 32-bit protected mode access for file manipulation and supports long filenames (LFNs)—up to 255 characters in Windows 95 and later. VFAT can also read disks prepared with the standard DOS 16-bit FAT. VFAT was called 32-bit file access in Windows for Workgroups. VFAT is not the same as FAT32.

VGA (video graphics array) A type of PC video display circuit (and adapter) first introduced by IBM on April 2, 1987, which supports text and graphics. Text is supported at a maximum resolution of 80×25 characters in 16 colors with a character box of 9×16 pixels. Graphics are supported at a maximum resolution of 320×200 pixels in 256 (from a palette of 262,144) colors or 640×480 pixels in 16 colors. The VGA outputs an analog signal with a horizontal scanning frequency of 31.5KHz and supports analog color or analog monochrome displays. Also refers generically to any adapter or display capable of 640×480 resolution.

VHS (Video Home System) A popular consumer videotape format developed by Matsushita and JVC.

video A system of recording and transmitting primarily visual information by translating moving or still images into electrical signals. The term *video* properly refers to only the picture, but as a generic term, *video* usually embraces audio and other signals that are part of a complete program. Video now includes not only broadcast television but many nonbroadcast applications, such as corporate communications, marketing, home entertainment, games, teletext, security, and even the visual display units of computer-based technology.

Video 8 or 8mm Video Video format based on the 8mm videotapes popularized by Sony for camcorders.

video adapter An expansion card or chipset built into a motherboard that provides the capability to display text and graphics onscreen. If the adapter is part of an expansion card, it also includes the physical connector for the monitor cable. If the chipset is on the motherboard, the video connector is on the motherboard as well.

video graphics array See *VGA*.

video-on-CD or video CD A full-motion digital video format using MPEG video compression and incorporating a variety of VCR-like control capabilities. See also *White Book*.

virtual disk A RAM disk or "phantom disk drive" in which a section of system memory (usually RAM) is set aside to hold data, just as though it were several disk sectors. To DOS, a virtual disk looks and functions like any other "real" drive.

virtual memory A technique by which operating systems such as 32-bit Windows versions load more programs and data into memory than they can hold. Parts of the programs and data are kept on disk and constantly swapped back and forth into system memory. The applications' software programs are unaware of this setup and act as though a large amount of memory is available.

virtual real mode A mode available in all Intel 80386-compatible processors. In this mode, memory addressing is limited to 4,096MB, restricted protection levels can be set to trap software crashes and control the system, and individual real-mode compatible sessions can be set up and maintained separately from one another.

virus A type of resident program designed to replicate itself. Usually at some later time when the virus is running, it causes an undesirable action to take place.

VL-Bus (VESA Local Bus) A standard 32-bit expansion slot bus specification used in 486 PCs, the VL-Bus connector was an extension of the ISA slot; any VL-Bus slot is also an ISA slot. Replaced by PCI bus, the VL-Bus slot was used on only a very few early Pentium systems.

VMM (Virtual Memory Manager) A facility in Windows enhanced mode that manages the task of swapping data in and out of 386 and later processor virtual real-mode memory space for multiple non-Windows applications running in virtual real mode.

voice-coil actuator A device that moves read/write heads across hard disk platters by magnetic interaction between coils of wire and a magnet. Functions somewhat like an audio speaker, from which the name originated. The standard actuator type on hard drives.

volatile memory Memory that does not hold data without power. Both Dynamic RAM (the main RAM in a computer) and Static RAM (used for cache memory) are considered volatile memory. See also *nonvolatile memory*.

voltage reduction technology An Intel processor technology that enables a processor to draw the standard voltage from the motherboard but run the internal processor core at a lower voltage.

voltage regulator A device that smoothes out voltage irregularities in the power fed to the computer.

volume A portion of a disk signified by a single drive specifier. Under DOS v3.3 and later, a single hard disk can be partitioned into several volumes, each with its own logical drive specifier (C:, D:, E:, and so on).

volume label An identifier or name of up to 11 characters that names a disk.

VPN (virtual private network) A private network operated within a public network. To maintain privacy, VPNs use access control and encryption.

VRAM (video random-access memory) VRAM chips are modified DRAMs on video boards that enable simultaneous access by the host system's processor and the processor on the video board. A large amount of information therefore can be transferred quickly between the video board and system processor. Sometimes also called dual-ported RAM. It has been replaced by SDRAM, SGRAM, and DDR SDRAM on recent high-performance video cards.

VxD (virtual device driver) A special type of Windows driver. VxDs run at the most privileged CPU mode (ring 0) and enable low-level interaction with the hardware and internal Windows functions.

W3C (World Wide Web Consortium) Sets standards for HTML, XML, and the Web.

wafer A thin, circular piece of silicon either 8" (200mm) or 12" (300mm) in diameter from which processors, memory, and other semiconductor electronics are manufactured.

wait states One or more pause cycles added during certain system operations that require the processor to wait until memory or some other system component can respond. Adding wait states enables a high-speed processor to synchronize with lower-cost, slower components. A system that runs with "zero wait states" requires none of these cycles because of the use of faster memory or other components in the system. The widespread use of L1 and L2 memory caches has made the issue of wait states largely irrelevant. See also *L1* and *L2*.

warm boot Rebooting a system by means of a software command rather than turning the power off and back on. See also *cold boot*.

wave table synthesis A method of creating synthetic sound on a sound card that uses actual musical instrument sounds sampled and stored on ROM (or RAM) on the sound card or in system RAM. The sound card then modifies this sample to create any note necessary for that instrument. Produces much better sound quality than FM synthesis.

Webcam An inexpensive (usually under $100) video camera that plugs into a USB or an IEEE-1394/FireWire port for use with video chat, Web sites, or email programs.

Whetstone A benchmark program developed in 1976 and designed to simulate arithmetic-intensive programs used in scientific computing. Remains completely CPU-bound and performs no I/O or system calls. Originally written in ALGOL, although the C and Pascal versions became more popular by the late 1980s. The speed at which a system performs floating-point operations often is measured in units of Whetstones.

White Book A standard specification developed by Philips and JVC in 1993 for storing MPEG standard video on CDs. An extension of the Red Book standard for digital audio, Yellow Book standard for CD-ROM, Green Book standard for CD-I, and Orange Book standard for CD write-once.

Whitney technology A term referring to a magnetic disk design that usually has oxide or thin film media, thin film read/write heads, low floating-height sliders, and low-mass actuator arms that together allow higher bit densities than the older Winchester technology. Whitney technology first was introduced with the IBM 3370 disk drive, circa 1979.

Wi-Fi Name for IEEE 802.11b-compliant network hardware that also meets the interoperability standards of the Wireless Ethernet Compatibility Alliance (WECA). Despite the presence of Wi-Fi approval for various brands of hardware, achieving the simplest setup and operation is still easier if you purchase Wi-Fi/802.11b wireless NICs and access points from the same vendor. See also *802.11 family*.

wide area network (WAN) A LAN that extends beyond the boundaries of a single building.

Winchester drive Any ordinary, nonremovable (or fixed) hard disk drive. The name originates from a particular IBM drive in the 1960s that had 30MB of fixed and 30MB of removable storage. This 30-30 drive matched the caliber figure for a popular series of rifles made by Winchester, so the slang term *Winchester* was applied to any fixed-platter hard disk.

Winchester technology The term *Winchester* is loosely applied to mean any disk with a fixed or nonremovable recording medium. More precisely, the term applies to a ferrite read/write head and slider design with oxide media that was first employed in the IBM 3340 disk drive, circa 1973. Virtually all drives today actually use developments of Whitney technology.

Wintel The common name given to computers running Microsoft Windows using Intel (or compatible) processors. A slang term for the PC standard.

wire frames The most common technique used to construct a 3D object for animation. A wire frame is given coordinates of length, height, and width. Wire frames are then filled with textures, colors, and movement. Transforming a wire frame into a textured object is called rendering.

word length The number of bits in a data character without parity, start, or stop bits.

workstation 1) A somewhat vague term describing any high-performance, single-user computer that usually has been adapted for specialized graphics, computer-aided design, computer-aided engineering, or scientific applications. 2) A computer connected to a server.

World Wide Web (WWW) Also called the Web. A graphical information system based on hypertext that enables a user to easily access documents located on the Internet.

WORM (write-once, read-many or multiple) An optical mass-storage device capable of storing many megabytes of information but that can be written to only once on any given area of the disk. A WORM disk typically holds more than 200MB of data. Because a WORM drive can't write over an old version of a file, new copies of files are made and stored on other parts of the disk whenever a file is revised. WORM disks are used to store information when a history of older versions must be maintained. Recording on a WORM disk is performed by a laser writer that burns pits in a thin metallic film (usually tellurium) embedded in the disk. This burning process is called ablation. WORM drives are frequently used for archiving data. WORM drives have been replaced by CD-R drives, which have a capacity of 650MB–700MB but have similar characteristics.

write precompensation A modification applied to write data by a controller to partially alleviate the problem of bit shift, which causes adjacent 1s written on magnetic media to read as though they were farther apart.

When adjacent 1s are sensed by the controller, precompensation is used to write them more closely together on the disk, thus enabling them to be read in the proper bit cell window. Drives with built-in controllers typically handle precompensation automatically. Precompensation usually is required for the inner cylinders of now-obsolete oxide media drives.

write protect Preventing a removable disk or Sony Memory Stick from being overwritten by means of covering a notch or repositioning a sliding switch, depending on the type of media.

X2 A proprietary modem standard developed by U.S. Robotics (since acquired by 3Com) that enables modems to receive data at up to 56Kbps. This has been superseded by the V.90 standard. See also *V.90* and *V.92*.

x86 A generic term referring to Intel and Intel-compatible PC microprocessors. Although the Pentium family processors do not have a numeric designation because of trademark law limitations on trademarking numbers, they are later generations of this family.

Xeon Intel's family name for its server processors derived from the Pentium II, Pentium III, and Pentium 4 desktop processors. The Pentium II Xeon and Pentium III Xeon use Slot 2, whereas Xeon (the Pentium 4 version does not have a numerical designation) uses the new Socket 602. All Xeon processors have larger caches and memory addressing schemes than their desktop counterparts.

XGA (extended graphics array) A type of PC video display circuit (and adapter) first introduced by IBM on October 30, 1990, that supports text and graphics. Text is supported at a maximum resolution of 132×60 characters in 16 colors with a character box of 8×6 pixels. Graphics are supported at a maximum resolution of 1,024×768 pixels in 256 (from a palette of 262,144) colors or 640×480 pixels in 65,536 colors. The XGA outputs an analog signal with a horizontal scanning frequency of 31.5KHz or 35.52KHz and supports analog color or analog monochrome displays. Also used to refer generically to any adapter or display capable of 1,024×768 resolution.

XML (eXtensible Markup Language) A standard for creating and sharing data and data formats over the Internet and other networks. XML, like HTML, uses markup tags to control the page, but XML tags control both appearance and the uses of the data and can be extended with new tags created by any XML user. See also *W3C*.

XMM (extended memory manager) A driver that controls access to extended memory on 286 and later processor systems. HIMEM.SYS is an example of an XMM that comes with DOS and Windows 9x.

Xmodem A file-transfer protocol—with error checking—developed by Ward Christensen in the mid-1970s and placed in the public domain. Designed to transfer files between machines running the CP/M operating system and using 300bps or 1,200bps modems. Until the late 1980s, because of its simplicity and public-domain status, Xmodem remained the most widely used microcomputer file-transfer protocol. In standard Xmodem, the transmitted blocks are 128 bytes. 1KB-Xmodem is an extension to Xmodem that increases the block size to 1,024 bytes. Many newer file-transfer protocols that are much faster and more accurate than Xmodem have been developed, such as Ymodem and Zmodem.

XMS (extended memory specification) A Microsoft-developed standard that provides a way for real-mode applications to access extended memory in a controlled fashion. The XMS standard is available from Microsoft.

XON/XOFF Standard ASCII control characters used to tell an intelligent device to stop or resume transmitting data. In most systems, pressing Ctrl+S sends the XOFF character. Most devices understand Ctrl+Q as XON; others interpret the pressing of any key after Ctrl+S as XON.

Y-connector A Y-shaped splitter cable that divides a source input into two output signals.

Y-mouse A family of adapters from P.I. Engineering that enables a single mouse port to drive two devices. P.I. Engineering also

makes the Y-see adapter for dual monitors and the Y-key adapter for dual keyboards.

Yellow Book The standard used by CD-ROM. Multimedia applications most commonly use the Yellow Book standard, which specifies how digital information is to be stored on the CD-ROM and read by a computer. Extended architecture (XA) is currently an extension of the Yellow Book that enables the combination of various data types (audio and video, for example) onto one track in a CD-ROM. Without XA, a CD-ROM can access only one data type at a time. Many CD-ROM drives are now XA capable.

Yellow Book standards See *CD-ROM*.

Ymodem A file-transfer protocol first released as part of Chuck Forsberg's YAM (yet another modem) program. An extension to Xmodem designed to overcome some of the limitations of the original. Enables information about the transmitted file, such as the filename and length, to be sent along with the file data and increases the size of a block from 128 bytes to 1,024 bytes. Ymodem-batch adds the capability to transmit batches, or groups, of files without operator interruption. YmodemG is a variation that sends the entire file before waiting for an acknowledgment. If the receiving side detects an error midstream, the transfer is aborted. YmodemG is designed for use with modems that have built-in error-correcting capabilities.

Z-buffering A 3D graphics technique used to determine which objects in a 3D scene will be visible to the user and which will be blocked by other objects. Z-buffering displays only the visible pixels in each object.

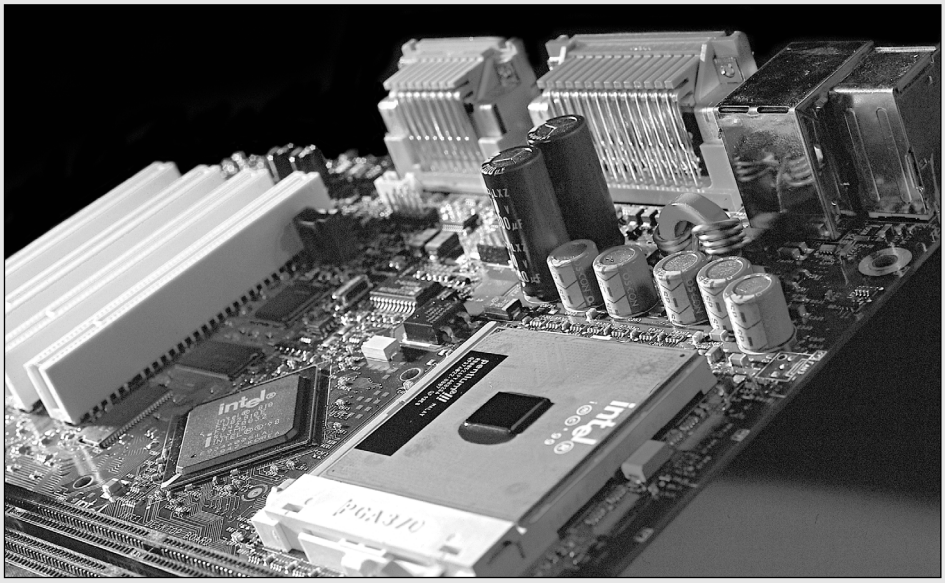
zero wait states See *wait states*.

ZIF (zero insertion force) Sockets that require no force for the insertion of a chip carrier. Usually accomplished through movable contacts, ZIF sockets are used by 486, Pentium, Pentium Pro, and other socketed processors (including the latest Pentium 4 and AMD Athlon and Duron models).

ZIP (zigzag inline package) A DIP package that has all leads on one edge in a zigzag pattern and mounts in a vertical plane.

Zip drive An external drive manufactured by Iomega that supports 100MB or 250MB magnetic media on a 3 1/2" removable drive.

Zip file A file created using PKZIP, WinZip, or a compatible archiving program.



zipping The process of creating a PKZIP or WinZip-compatible archive file. See also *unzipping*.

Zmodem A file-transfer protocol commissioned by Telenet and placed in the public domain. Like Ymodem, it was designed by Chuck Forsberg and developed as an extension to Xmodem to overcome the inherent latency when using Send/Ack-based protocols, such as XModem and YModem. It is a streaming, sliding-window protocol.

zoned recording In hard drives, one way to increase the capacity of a hard drive is to format more sectors on the outer cylinders than on the inner ones. Zoned recording splits the cylinders into groups called zones, with each successive zone having more and more sectors per track, moving out from the inner radius of the disk. All the cylinders in a particular zone have the same number of sectors per track.

zoomed video A direct video bus connection between the PC-Card adapter and a mobile system's VGA controller, enabling high-speed video displays for videoconferencing applications and MPEG decoders.

APPENDIX B

Key Vendor Contact Information

Use this vendor quick reference chart to locate primary contact information for vendors mentioned in this book. Be sure to refer to the vendor database included on the DVD accompanying this book. This database contains detailed contact information and descriptions of services and is keyword searchable.

APPENDIX C

Troubleshooting Index

This special index is designed to help you find solutions to problems—*fast*. Whether your system is beeping at startup, you're getting the dreaded blue screen of death, or you can't hear your rocket launcher blasts in your latest Unreal Tournament Deathmatch, this index will help you find solutions, quickly and relatively painlessly.

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Audio	Your sound card doesn't sound quite right.	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	337
Audio	Sound card can't be detected.	Settings already in use by other cards.	Install sound card first.	344
Audio	Can hear music and sounds in Windows but not DOS.	Incorrect settings for Sound Blaster compatibility.	Configure emulation settings in Device Manager; run SB Pro emulation program in DOS.	923
Audio	DOS game can't detect sound card correctly.	Inadequate Sound Blaster compliance or missing DOS drivers.	Verify DOS drivers are installed and manually select best emulation.	933
Audio	Game port on sound card conflicts with other game port in system.	Game port can uses only a single I/O address range.	Disable sound card's game port or remove other game port from system.	950
Audio	Can't hear any sounds at all.	Various causes, including incorrect connections, mixer setup, power, and so on.	See checklist.	947
Audio	Can hear sound through just one speaker.	Various causes, including incorrect or defective speaker jack/plug, mixer controls, and others.	See checklist.	952

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Audio	Volume is low.	Various causes, including mixer controls, volume controls on speakers or sound card.	See checklist.	953
Audio	Scratchy sound.	Various causes, including interference, ISA sound card, wrong expansion slot.	See checklist.	954
Audio	Computer won't start after installing sound card.	Card might not be installed in slot properly, or Windows IOS might be corrupted.	See checklist.	954
Audio	Speaker or microphone won't work.	Incorrect jacks.	Use correct jack for each device.	958
Audio	Can't use onboard audio.	Audio might be disabled in BIOS.	Enable audio.	380
Battery for CMOS/RTC	System can't maintain correct time when turned off.	Battery is about to fail.	Replace battery.	1214
BIOS	Calendar-related and leap-year bugs.	BIOS is out-of-date.	Upgrade Flash BIOS.	373
BIOS	Can't install Flash BIOS update.	BIOS is write-protected.	Disable write-protection.	376
BIOS	BIOS update fails.	BIOS is corrupted.	Enable Flash Recovery feature and restart update process.	378

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
CD-ROM	Can't boot from CD-ROM drive.	BIOS is out-of-date.	Upgrade Flash BIOS.	373
DirecWay	Download speeds drop drastically after downloading one or two large files.	DirecWay has enabled FAP (Fair Access Policy) slowdowns on your service.	Download less at one time; take breaks between big downloads, or switch to another service.	1063
DSL	Can't use DSL service after self-install.	Service might not be set up by provider; microfilter might not be installed as needed.	Make sure provider has activated DSL service; make sure all conventional phones and telephony equipment has a microfilter.	1050
File transfer	Can't connect two computers with standard parallel cable.	Standard parallel is designed for PC-to-device, not PC-to-PC connections.	Use a LapLink-compatible parallel cable.	990
Floppy disk	Can't write data to floppy disk; data can be read.	Floppy disk write protection is enabled in BIOS.	Disable floppy disk write protection.	397
Floppy disk	`File Copying Error` message when copying files with long filenames to disk.	Long filenames might use multiple directory entries, depending on length of filename.	Create subfolder on floppy disk and store files with long filenames in folder.	1356
Floppy drive	Disk left in floppy drive prevents system bootup.	Floppy drive has higher boot priority than hard drive.	Adjust boot priority in system BIOS.	404

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Floppy drive	Contents of all floppy disks viewed appear to be duplicates of the first disk, although the contents of each disk are different.	Change line support (which detects disk changes) has failed; this problem is also called the "phantom directory."	Verify BIOS setup for drive is correct and that DC jumper (if any) has been set.	654
Floppy drive	Disks placed on top of a TV or monitor have data errors when read.	Magnetic fields generated by the picture tube can corrupt data.	Store disks away from magnetic fields.	661
Floppy drive	Dead drive—the drive does not spin and the LED never comes on.	Drive or controller not properly configured in BIOS setup.	Verify floppy controller is enabled and correct drive type selected.	663
Floppy drive	Dead drive—the drive does not spin and the LED never comes on.	Bad power supply or bad cable.	Use voltmeter to check power going to drive.	663
Floppy drive	Dead drive—the drive does not spin and the LED never comes on.	Defective data cable.	Make sure cable is connected properly; replace.	663
Floppy drive	Dead drive—the drive does not spin and the LED never comes on.	Defective drive.	Replace and retest.	663
Floppy drive	Dead drive—the drive does not spin and the LED never comes on.	Defective floppy controller.	Try drive/cable on another system; if they work there, replace motherboard or card containing controller.	663
Floppy drive	Drive LED remains on continuously.	Data cable attached backwards.	Remove and reattach cable correctly.	663

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Floppy drive	Drive LED remains on continuously.	Data cable attached offset to pins.	Remove and reattach cable correctly.	663
Floppy drive	`Invalid Media` or `Track Zero Bad, Disk Unusable` error.	Incorrect disk-type parameters might have been used during format process.	Use correct disk-type parameters when formatting the disk.	663
Floppy drive	`Invalid Media` or `Track Zero Bad, Disk Unusable` error message.	Drive heads might be dirty.	Use floppy disk head cleaner and retry.	663
Floppy drive	`Invalid Media` or `Track Zero Bad, Disk Unusable` error message.	Defective or damaged floppy disk.	Use a different disk and retry.	663
Floppy drive	`CRC Error` or `Disk Error 23` error message.	Data read from disk does not match data written.	Clean disk heads and retry; use Norton Disk Doctor.	663
Floppy drive	`General Failure Reading Drive A; Abort, Retry, Fail;` or `Disk Error 31` error message.	Disk isn't formatted or was formatted for a different operating system (such as a Macintosh).	Format the disk and retry.	663
Floppy drive	`General Failure Reading Drive A; Abort, Retry, Fail;` or `Disk Error 31` error message.	Disk surface damaged.	Use Norton Disk Doctor to retrieve any readable data.	663
Floppy drive	`Access Denied` error.	Disk is write-protected.	Remove disk, write-enable disk, and retry write operation.	663

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Floppy drive	`Access Denied` error.	File has read-only attributes set.	Remove read-only attributes with Windows Explorer or DOS Attrib and retry write or delete operation.	663
Floppy drive	`Insufficient Disk Space` or `Disk Full` error.	Disk has insufficient space overall or in root directory for new files.	Use a different disk, or delete files.	663
Floppy drive	`xxx bytes in bad sectors` error.	Displayed when `ScanDisk`, `CHKDSK`, or `Format` is run on disks with bad sectors.	Move data on disk to other storage and reformat.	663
Floppy drive	`Disk Type Incompatible`, `Drive Types Incompatible or Bad` error.	Displayed when trying to use `DISKCOPY` on disks with different sizes.	Use `XCOPY` instead; use `DISKCOPY` only for disks with same size and capacity.	663
Floppy drive	Disk access light stays on continuously after system is started.	One end of floppy cable is reversed.	Change reversed end of floppy cable, verifying pin 1 to pin 1.	845
Hard disk	Can't access full capacity of hard drive over 8.4GB.	BIOS is out-of-date.	Upgrade Flash BIOS.	373
Hard disk	Can't use UDMA drives at full speed.	BIOS is out-of-date.	Upgrade Flash BIOS.	373
Hard disk	`IDE drive not ready` errors during startup.	Drive not spinning up fast enough at startup.	Enable or increase hard disk predelay time.	394
Hard disk	Can't use drive capacity beyond 528MB.	LBA mode not enabled in BIOS.	Enable LBA mode.	395

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Hard disk	Boot section corrupted.	Boot sector virus or other problem.	Use `FDISK/MBR` (DOS, Windows 9x/Me) or `FIXMBR` (Windows NT/2000) to restore.	1346
Hard disk	Storing small file uses up a large amount of space on drive.	Files smaller than an allocation unit (cluster) still use an entire allocation unit.	Convert drive to FAT32 or NTFS to be more efficient if possible; remove outdated files from system to save space.	1354
Hard disk	Your 40GB hard disk can't be formatted by Windows 2000 or Windows XP as a single drive with FAT32.	These versions can format up to 32GB only, but can read larger drives.	Prepare drive with third-party utility such as PartitionMagic or use NTFS.	1359
Hard disk	Large numbers of files ending in .CHK are found in root directory of drive.	.CHK files are created by `SCANDISK` or `CHKDSK` from lost allocation units.	Shut down system properly to avoid lost allocation units; test drive if problem persists; delete files to free up space.	1364
Hard drive	UDMA/66 or UDMA/100 drive runs at UDMA/33 on systems that support UDMA/66 or UDMA/100.	Incorrect cable might be in use.	Use 80-wire UDMA cable in place of normal 40-wire IDE cable.	500
Hard drive	System won't boot after installing new IDE drive.	Cable might be reversed.	Make sure pin 1 on both ends of cable is connected to interfaces' pin 1.	502
Hard drive	Can't set IDE drives as master or slave when 80-wire cable is used.	80-wire cable supports cable select, not master/slave.	Install drives at correct locations on cable, and jumper both as Cable Select.	500

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Hard drive	Can't read contents of IDE drive over 528MB after moving it to a new system.	Drive geometry or translation not set correctly on new system.	Set correct Cyl-Hd-Sectors setting for drive and LBA or Ext CHS translation.	512
Hard drive	BIOS recognizes full capacity of drive over 8.4GB, but operating system will not.	Some operating systems aren't designed to use drives over 8.4GB.	Upgrade or patch your operating system to achieve compliance.	525
Hard drive	Can't boot from SCSI hard drive.	SCSI BIOS might not be enabled; system BIOS might not be set properly.	Enable SCSI BIOS and disable booting from IDE drives in system BIOS.	564
Hard drive	`Immediately back up your data and replace your hard disk drive. A failure may be imminent.` error message is seen.	The drive uses S.M.A.R.T. to predict failures, and the S.M.A.R.T. system has detected a serious problem with the drive.	Follow the onscreen instructions to back up your drive.	637
Hard drive	Hard drive letters above C: are pushed higher when second drive is installed.	New drive was prepared with a primary partition, which takes precedence over drive letters in the first drive's extended partition.	Prepare additional drives with an extended partition.	827
Hard drive	`Invalid Drive Specification` error.	Drive has not been partitioned or high-level formatted, or wrong OS being used to view drive.	Verify drive is empty with recent Windows versions before running `FDISK` and `FORMAT`.	837

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Hard drive	`Invalid Media Type` error.	Drive has not been FDISKed, or drive's format is corrupt.	View drive with FDISK's #4 option, and create new partitions as necessary.	837
IDE drives	Can't detect drive with BIOS setup program.	Power cable might be loose or missing.	Reattach power cable.	821
IDE drives	Can't detect drive with BIOS setup program.	Missing or reversed IDE data cable.	Rettach IDE data cable and verify pin 1 to pin 1 at both ends of cable.	821
IDE drives	Can't detect either drive on cable with BIOS setup program.	Both drives might be cabled as master or slave.	Change one drive to master and the other drive to slave.	838
Internet	Can't share Internet connection.	Problems with host or client configuration.	See checklist.	1096
IRQ	Conflicts between PCI devices.	PCI IRQ steering not enabled.	Enable PCI IRQ steering.	328
IRQ	Conflicts between COM ports.	IRQs shared between COM 1 and 3; between COM 2 and 4.	Disable unused COM port or change IRQ if possible.	331
ISA cards	ISA cards have hardware conflicts with PCI cards.	Resources not reserved for ISA cards.	Reserve resources for ISA cards.	399
Keyboard	Num Lock stays off when starting. system.	Num Lock shut off in BIOS.	Turn on Num Lock in BIOS.	389
Keyboard	Intermittent keyboard failures.	Keyboard cable or keyboard jack might be defective.	Test keyboard cable or jack with digital multimeter.	1017

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Keyboard	Keys are sticking.	Keyboard might have spilled drink or trapped debris under keys.	Remove keytops and clean under keys, or wash out keyboard.	1018
LAN	Can't use onboard LAN.	LAN might be disabled in BIOS.	Enable audio.	392
Modem	Internal modem locks up system when trying to make a connection.	Modem might be set to same IRQ as the serial port the mouse is attached to.	Disable the unused COM port on the system, and set the modem to use that COM port number.	983
Modem	Modem works correctly with Internet access, but computer-to-computer terminal emulation produces garbage screens.	Incorrect bps, word length, stop bit, or terminal emulation settings compared to remote system's requirements.	Determine correct values for remote system and set up HyperTerminal or other connection program accordingly.	1072
Modem	56Kbps modem connects at 33.6Kbps or less.	Some telephone lines can't provide greater than 33.6Kbps service.	Switch to a broadband service, or use modem bonding to achieve higher speeds.	1080
Modem	K56flex modem connects at lower speeds after update to V.90.	K56flex might work better than V.90 for some users with certain modems and ISPs.	See checklist.	1082
Modem	Modem drops calls unexpectedly.	You might have call-waiting enabled, which interrupts the modem carrier signal.	Disable call-waiting (ask phone company for details), or upgrade to modems with call-waiting support.	1086

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Modem	Can't dial with analog modem.	Various causes.	See checklist.	1097
Modem	System locks up after installing internal modem.	IRQ conflicts with other ports or devices.	See checklist.	1098
Modem	Computer can't detect external modem.	Wrong cable, port problems, or power problems.	Check cable, port setup, and power.	1099
Motherboard	Damage to motherboard from heatsink clips on socketed processors.	Clips slip and scratch motherboard surface.	Attach plastic tape on motherboard before installing heatsink.	107
Mouse	Mouse doesn't work.	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	337
Mouse	Can't use PS/2 mouse.	PS/2 mouse port might be disabled.	Enable PS/2 mouse port.	406
Mouse	Mouse doesn't work when attached via adapter to a different port type.	Mouse might not be hybrid type (designed for various ports).	Use adapters only with hybrid mice; use adapter packaged with mouse.	1025
Mouse	Mouse pointer jerks onscreen.	Mouse ball or rollers are dirty.	Clean mouse mechanism.	1026
Mouse	Mouse works for basic operations, but extra buttons or scroll doesn't work.	Incorrect or outdated mouse driver is being used.	Download and install correct mouse driver from vendor site.	1020
Mouse	Mouse works in Windows, but not when booted to DOS.	DOS driver must be loaded from `AUTOEXEC.BAT` or `CONFIG.SYS`.	Install DOS mouse driver and reference it in startup file(s).	1028

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Network	System locks up after installing network card.	IRQ conflicts with other ports or devices.	See checklist.	1098
Network	Can't connect to other computers on network after installing a new custom-built cable.	Cable might not match prevailing wiring standard on network.	Check wiring of other cables to see which wiring standard is used; build new cable to match.	1125
Network	Distant computer works with 10BASE-T network but not with Fast Ethernet.	Computer might be too far from hub or switch because Fast Ethernet has shorter maximum distance.	Install repeater, or use new switch/hub as repeater.	1130
Network	Can't connect to other users on network, although card diagnostics check out.	Might not have correct network software components installed.	See checklist.	1149
Network	`Duplicate computer ID` error.	More than one computer has the same name or IP address on the network.	Adjust computer name or IP address with the Network properties sheet.	1152
Network	Users can't see all the computers on the network.	Multiple workgroup names are in use.	Adjust workgroup name (must match for all on network) with Network properties.	1152
Network	Users can't share printers or folders with others.	File/Print sharing might not be installed; folders or printers might not be set to shared.	Install File/Print sharing, and then set shared folders and printers.	1152

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Network	Network changes made, but don't work.	Most Windows systems must be rebooted to put network changes into effect.	Reboot system and then try network operations.	1152
Network	One user can't access network, but others can.	User might not have logged on to network.	Log off system and log on; provide name and password when prompted.	1153
Network	One user can't access network, but others can.	Loose cables at computer, hub, switch, or wiring closet.	Check all cable connections.	1153
Network	One user can't access network, but others can.	Password cache might be corrupt or have outdated passwords.	Log on to resources again and give new password when prompted.	1153
Network	Can't access Internet or other TCP/IP-based resources.	Wrong TCP/IP settings.	Open Network properties sheet and adjust TCP/IP settings as needed for your network.	1154
Network	`IP Address Conflict` error.	Duplicate IP addresses on two or more machines.	Open Network properties sheet and enter correct, unique IP addresses for each system.	1154
Optical drives	Drive letters above C: are pushed higher when new hard drives are installed.	Hard drives take precedence over optical drives.	Set optical drives to reserved drive letters above those needed by hard drives.	685
Optical drives	Drive slows down when reading CD with a small paper label attached to the label side.	Drive can't run at full speed due to uneven weight distribution and must slow down.	Use full-size labels that cover the entire CD's top surface, or use a marker instead of small labels.	730

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Optical drives	CD-ROM drive can't read multiple-session disc.	Drive is not compatible with Orange Book multisession standard (XA standard).	Replace drive with new CD-ROM, CD-RW, or DVD drive.	739
Optical drives	Can't read CD-R or CD-RW disc on a CD-ROM drive, but only on a CD-R/CD-RW drive.	CD probably was created with packet-writing software and not closed before being removed.	Return CD-R or CD-RW disc to original system and close session.	740
Optical drives	CD-ROM disc can be read by 32-bit Windows but not by DOS.	CD was created using the UDF (packet-writing) standard.	Use standard mastering software instead of DirectCD to create CDs for use with DOS.	747
Optical drives	Drive runs very slowly or has read errors.	CD lens might be dirty or dusty.	Use a CD lens cleaner, or install a drive with a self-cleaning lens.	746, 809
Optical drives	Can't read CD-RW media on an older drive.	Drives that aren't MultiRead compliant can't read CD-RW media (usually slower than 24x speed).	Replace drive with a MultiRead-compatible CD-ROM or DVD drive or a CD-RW drive.	787
Optical drives	Can't write to a 10x CD-RW disc in a 4x CD-RW drive.	10x media meets the High-Speed ReWritable standard, not supported by 2x and 4x CD-RW drives.	Use 2x or 4x media for interchange between 10x and 2x/4x CD-RW drives.	784
Optical drives	Can't read CD-RW media in a DVD.	Drives that aren't MultiRead2 compliant can't read CD-RW or DVD-RAM media.	Replace drive with a MultiRead2 drive.	787

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Optical drives	Can't burn a CD-R disc while performing other tasks.	Multitasking operations are causing buffer underruns.	Run only CD-mastering software, slow down burn speed, or upgrade to a drive with buffer underrun protection.	788
Optical drives	CD-ROM has a different drive letter when command-prompt/DOS is run than in Windows.	CD-ROM has been assigned a specific drive letter in Windows, but defaults to the next available drive letter in DOS.	Use the /L:x option with MSCDEX in DOS to assign the drive letter used in Windows to the drive; replace x with the drive letter.	804
Optical drives	Can boot from bootable CD, but can't read contents of CD.	Bootable CD must have CD-ROM driver files and `CONFIG.SYS` and `AUTOEXEC.BAT` references to them.	Make sure bootable disk used for creating bootable CD can access CD-ROM.	811
Optical drives	Can't read CD or CD-R discs in a CD-ROM or DVD drive.	Media might not be compatible.	Try different-colored media.	810
Optical drives	ATAPI drive runs very slowly, but no read errors.	Wrong cache size.	Adjust cache size in Performance tab of System Properties.	810
Optical drives	ATAPI drive runs very slowly, but no read errors.	CD-ROM drive on same cable as hard drive.	Move CD-ROM drive to secondary cable.	810
Optical drives	ATAPI drive runs very slowly, but no read errors.	UDMA or busmastering drivers might not be installed or enabled.	Install and enable latest UDMA or busmastering drivers.	810

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Optical drives	ATAPI drive runs very slowly, but no read errors.	Drive might be using MS-DOS Compatibility Mode (BIOS-based) access.	Reinstall drive to use 32-bit Windows drivers.	810
Optical drives	Can't boot from bootable CD.	System might not support bootable CD.	Verify CD-ROM listed as bootable device and listed first in boot.	811
Optical drives	Can't boot from bootable CD.	Wrong disc format (Joliet or other).	Must use ISO 9660 CD format.	811
Optical drives	Can't boot from bootable CD.	SCSI drive and host adapter might not be configured as bootable.	Enable BIOS on SCSI adapter and disable IDE boot devices in system BIOS.	811
Optical drives	Can't hear music through sound card speakers.	Analog or digital audio cables aren't connected between drive and audio jacks on sound card or motherboard with integrated sound.	Reattach cables to drive and sound card or motherboard; check mixer settings.	924, 927
Parallel port	Can't use onboard parallel port.	Port might be disabled in BIOS.	Enable port.	392
Parallel port	Conflict between onboard parallel port and other device.	IRQ or I/O port address conflicts with other device.	Adjust IRQ or I/O port address in use, or disable port.	392
Parallel port	Can't use ECP mode.	DMA channel conflicts with another device.	Use alternate DMA channel, or use EPP mode instead.	392

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Parallel port	Can't use parallel port drives connected to USB-to-parallel adapters.	USB-to-parallel adapters are designed to support printers, not other parallel port devices.	Connect parallel port devices to the parallel port, or upgrade to USB devices.	971
Password	Can't access setup or start system because system prompts for password.	Setup and/or power-on passwords are enabled in BIOS.	Clear password settings.	385, 400
Password	Can't access setup or start system because system prompts for password.	Setup and/or power-on passwords are enabled in BIOS.	Clear CMOS if password settings can't be cleared separately.	400
PCI	IRQ conflicts between PCI cards.	IRQs might be shared between slots.	Move conflicting cards to another PCI slot.	389
PCI	IRQ conflicts between PCI cards.	Auto PCI IRQ Priority might not work for all cards.	Set PCI IRQ priority manually.	389
PnP	Can't install new PnP cards.	PnP/PCI configuration data might be corrupted.	Clear PnP/PCI configuration data and restart system.	389
PnP	Problems with PnP cards and configuration.	BIOS is out-of-date.	Upgrade Flash BIOS.	373
Power management	System can't use power management features.	Power management disabled.	Enable power management.	401
Power management	Can't control power management through Windows.	ACPI power management disabled.	Enable ACPI power management.	401
Power management	Can't use ACPI power management.	BIOS is out-of-date.	Upgrade Flash BIOS.	373

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Power management	System locks up or hardware malfunctions when power management is used.	Some older peripherals are not compatible with power management.	Disable APM power management in the system BIOS; disable ACPI power management with Windows' Power properties sheet.	1197
Power supply	System reboots (cold boots with memory check) spontaneously.	Power Good voltage level out of limits.	Check power supply with DMM; replace power supply if defective.	1202
Power supply	Dell power supply fails and replacement has different-colored wires for connectors.	Dell changed to a nonstandard version of ATX for systems built September 1998–2000; standard power supplies will not work and will fry!	Buy a Dell-brand or Dell-compatible power supply, or replace motherboard and power supply with standard models.	1177
Power supply	System won't start; power is going to system.	Voltage slider on power supply might be set to wrong voltage.	Set power supply to correct voltage level for local current.	1186
Power supply	Power supply fails after additional components are added to system.	New components require more 5V power than old power supply can provide.	Replace failed unit with a 300-watt or larger unit.	1192
Power supply	Hard disk or fan won't turn.	Defective or overloaded power supply.	Replace failed unit with a 300-watt or larger unit.	1198
Power supply	Electrical shocks on case.	Defective or overloaded power supply.	Replace failed unit with a 300-watt or larger unit.	1198

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Printer	Parallel printer prints very slowly.	Printer might be attached to non-EEE or non-ECP parallel port.	Set port to use mode recommended for printer and switch to IEEE-1284 cable if necessary.	986
Printer	Your printer prints gibberish.	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	337
Processor	Can't overclock multiplier.	Multiplier locked on recent AMD, Intel CPUs.	Adjust bus speed instead.	84
Processor	Can't use FC-PGA processor in PGA-370 socket.	Change in voltages and pinout.	Upgrade motherboard or use third-party PGA/FC-PGA adapter.	98
Processor	Can't use PGA or FC-PGA processor in Slot 1.	Wrong form factor.	Use slot-key adapter.	98
Processor	Poor heat transfer from processor to heatsink.	Gaps between processor and heatsink faceplate.	Attach thermal interface pad or grease to processor before attaching heatsink.	107
Processor	Pentium miscalculates floating-point math.	Errata 23 in Pentium processor.	Have Intel replace affected Pentium or use updated processor.	141
Processor	Improper CPU identification during POST.	Old BIOS.	Update BIOS from manufacturer.	198
Processor	Improper CPU identification during POST.	Board is not configured properly.	Check manual, and set board accordingly to proper bus and multiplier settings.	198

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Processor	Can't install newer processors.	BIOS is out-of-date.	Upgrade Flash BIOS.	373
RAM	RAM test not detecting any problems and is finishing too quickly.	L1 and L2 memory caches might be enabled.	Disable memory caches before testing memory.	406
RAM	Soft (random) errors occur after adjusting memory timing in BIOS setup.	Refresh rate set incorrectly in BIOS.	Autoconfigure memory timing in BIOS.	390
RAM	Can't use standard 30-pin or 72-pin SIMMs in some IBM, Compaq, or HP systems.	These systems support nonstandard presence detect pins in the SIMMs.	Use SIMMs made especially for the computer model.	439
RAM	Can't insert 168-pin DIMM into the motherboard.	DIMM might be wrong voltage or type for motherboard.	PCs use unbuffered 3.3v DIMMs; others will not fit.	442
RAM	RIMM-based system won't boot up with some RIMM sockets empty.	All RIMM sockets must have memory or continuity module installed.	Install continuity modules into a RIMM socket without memory.	431
RAM	Can't determine speed or type of memory module.	Some memory modules aren't labeled.	Look up memory chip characteristics to determine module speed and type.	449
RAM	Single 72-pin SIMM not recognized on P5-class system.	Memory must be added in banks of 64 bits on P5-class systems; 72-pin SIMM has 32 bits.	Add pair of identical SIMMs as supported by motherboard.	452

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
RAM	System won't boot after installing new memory.	Memory might be too slow for system.	Install new memory as fast or faster than previous memory.	453
RAM	System locks up; mixed metals (gold/tin) used in sockets and modules.	Corroded memory sockets result from mixing tin sockets/gold memory or vice versa.	Remove memory, clean sockets, and use memory with same metal as sockets.	454
RAM	Soft (random) memory errors.	Power glitches or noise on the line.	Replace power supply if it tests out-of-spec, or install power conditioning equipment.	457
RAM	Soft (random) memory errors.	Incorrect type or speed.	Use memory that matches recommended type and meets or exceeds recommended speed.	457
RAM	Soft (random) memory errors.	RF (Radio Frequency) interference.	Move causes of RF away from system.	457
RAM	Soft (random) memory errors.	ESD (electro-static discharge).	Use antistatic spray on screen and keyboard and install antistatic mats near system.	467
RAM	Memory parity interrupt error message.	Parity checking has detected an error in RAM.	Shut down the system and restart it; remove and reinstall memory.	459
RAM	`Out of memory` error after upgrading system with AGP card beyond 512MB of RAM.	Windows 9x/Me can't handle memory addresses beyond 512MB along with AGP aperture addresses.	Use no more than 512MB of RAM with Windows 9x/Me and AGP video.	889

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Removable media	Can't boot from SuperDisk LS-120 drive.	BIOS is out-of-date.	Upgrade Flash BIOS.	373
Removable media	Iomega Zip drive makes clicking noises and won't read media.	Drive or media has "click of death" problem.	Check media for damage; run TIP testing program on disk; use Iomega diagnostics on drive.	674
Removable media	Iomega Jaz drive makes clicking noises and won't read media.	Drive or media has "click of death" problem.	Check media for damage; run TIP testing program on disk; use Iomega diagnostics on drive.	679
Removable media	Castlewood Orb drives can't read media.	Drivers might be clashing with Iomega drivers.	Remove Iomega drivers, reinstall Orb drivers; then download and install new Iomega drivers.	680
Removable media	Castlewood Orb drives can't read media.	Orb drivers might be out-of-date.	Download and install latest drivers and firmware from Castlewood's Web site.	680
Removable media	Castlewood Orb drives can't read media.	Drive might not be spinning up completely before being read.	Allow drive to spin up completely before accessing it.	680
Removable media	Drive letters above C: are pushed higher when new hard drives are installed.	Hard drives take precedence over removable-media drives.	Set removable-media drives to reserved drive letters above those needed by hard drives.	806

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Removable-media drive	Can't boot from LS-120/ LS-240 Super-Disk or Zip drive.	ARMD-FDD (ATAPI Removable Device—Floppy), Zip, or LS-120 drive listed after hard drive in boot order.	Adjust boot priority in system BIOS.	404
SCSI	Data or signaling errors at higher speeds.	Passive termination not suitable for use in faster SCSI versions.	Use other types of terminators at both ends of SCSI daisy-chain.	556
SCSI	Can't use external SCSI device.	External device might have been turned on after system startup.	Turn on external devices first; then boot system.	564
SCSI	Can't detect new SCSI device.	Device might be using a duplicate device ID.	Ensure that each device and the host adapter use a unique device ID.	564
SCSI	PCI SCSI card doesn't work properly.	PCI SCSI cards require a busmastering PCI slot.	Move card to a slot that supports busmastering.	564
Serial port	Can't use onboard serial port.	Port might be disabled in BIOS.	Enable port.	392
Serial port	Conflict between onboard serial port and other device.	IRQ or I/O port address conflicts with other device.	Adjust IRQ or I/O port address in use, or disable port.	392
Serial port	COM 3 and above work in Windows, but not DOS.	DOS can use only COM 1 and COM 2 due to BIOS limitations.	Use only COM 1 or COM 2 for DOS applications.	981

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Startup	System won't start; no error messages onscreen.	Various fatal errors.	Install POST card; restart system to determine error codes and diagnose problem.	410
Startup	System won't start; various error messages indicating system can't boot.	Hard disk might not be connected to system, partitioned, formatted, or set up correctly in BIOS.	Check drive cabling, drive partitions, and BIOS configuration.	412
Startup	Problems during POST.	Various causes.	See checklist.	1335
Startup	System beeps several times when turned on; doesn't start properly.	Serious or fatal hardware errors.	Count beeps and pattern; determine BIOS used and look up beep code to determine problem.	1274
Startup	System displays error message when turned on; doesn't start properly.	Serious hardware error.	Look up error code in Technical Reference on CD.	1274
Startup	System doesn't start properly; might not beep or display error codes.	Serious or fatal hardware errors.	Install POST diagnostics card and restart system; look up I/O port POST codes.	1274
Startup	System can't boot from hard drive.	Configuration problem with system or drive.	See checklist.	1295
Startup	`Missing Operating System` error.	Incorrect drive geometry settings, bad CMOS battery, no active partition, bad MBR.	See checklist.	1377

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Startup	`NO ROM BASIC - SYSTEM HALTED` error.	Incorrect drive geometry settings, bad CMOS battery, no active partition, bad MBR.	See checklist.	1378
Startup	`Boot error Press F1 to retry` error.	Incorrect drive geometry settings, bad CMOS battery, no active partition, bad MBR.	See checklist.	1378
Startup	`Invalid drive specification` error.	No partition on disk.	Use FDISK or equivalent to partition drive.	1378
Startup	`Invalid Media Type` error.	No valid format on drive.	Use `FORMAT` or Norton Disk Doctor.	1378
Startup	`Hard Disk Controller Failure` error.	Incorrect cabling between drive and host adapter or failed host adapter.	Check cables; then check host adapter.	1378
System	Problems with adapter cards.	Various causes.	See checklist.	1336
System	System unstable when overclocking.	Incorrect voltage to processor.	Use motherboard that allows fine adjustments to processor voltage.	58
System	System is dead, no beeps, no cursor, no fan.	Power cord failure.	Plug in or replace power cord.	198
System	System is dead, no beeps, no cursor, no fan.	Power supply failure.	Replace power supply with known good one.	198

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
System	System is dead, no beeps, no cursor, no fan.	Motherboard failure.	Replace motherboard with known good one.	198
System	System is dead, no beeps, no cursor, no fan.	Memory failure.	Remove all memory except bank 1 and retest; swap bank 1 if no boot.	198
System	System is dead, no beeps, or locks up before POST begins.	All components either not installed or incorrectly installed.	Check all peripherals, especially memory and graphics adapter. Reseat all boards and socketed components.	198
System	System beeps on startup, fan is running, no cursor onscreen. Locks up during or shortly after POST.	Improperly seated or failing graphics adapter.	Reseat or replace graphics adapter. Use known good spare for testing.	198
System	System beeps on startup, fan is running, no cursor onscreen. Locks up during or shortly after POST.	Poor heat dissipation.	Check CPU heatsink/fan; replace if necessary; use one with higher capacity.	198
System	System beeps on startup, fan is running, no cursor onscreen. Locks up during or shortly after POST.	Improper voltage settings.	Set motherboard for proper core processor voltage.	198

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
System	System beeps on startup, fan is running, no cursor onscreen. Locks up during or shortly after POST.	Wrong motherboard bus speed.	Set motherboard for proper speed.	198
System	System beeps on startup, fan is running, no cursor onscreen. Locks up during or shortly after POST.	Wrong CPU clock multiplier.	Jumper motherboard for proper clock multiplier.	198
System	Device transfers data inaccurately.	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	337
System	System frequently locks up.	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	337
System	Hardware and software bugs.	BIOS is out-of-date.	Upgrade Flash BIOS.	373
System	Slow system performance.	System BIOS might not be cached.	Enable caching of system BIOS.	390
System	Memory address conflict between devices.	Two devices are using the same upper memory block.	Move one device to a nonconflicting UMB address.	489
System	Intermittent lockups, memory and drive glitches.	Improperly wired outlets might be providing bad power.	Use an outlet tester to check ground and polarity.	1314

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
System	Intermittent lockups, memory and drive glitches.	Other devices on circuit could be causing problems, such as AC units, coffee makers, and so on.	Move computers to their own circuit.	1332
System	Problems after system startup with hardware.	Various causes.	See checklist.	1336
Tape drives	Tape drive can't write to older tape but can read contents of same tape type.	Most drives have limited write compatibility, but can read a wider variety of tapes.	Use correct tape type for new backups; check for write-protect setting on cartridge.	698
Tape drives	Can't run tape backup or restore; bad block errors during restore.	Defective tape cartridge, dirty heads, defective cabling, or incorrect software settings.	Replace cartridge, clean heads, check cabling, and rerun confidence test with blank cartridge.	712
USB	Can't use USB ports on system.	USB ports might be disabled, or your system has the wrong Windows version.	Enable USB ports in BIOS, and verify you are using Windows 98, Me, 2000, or XP.	968
USB	USB ports available in BIOS but not visible on system.	USB header cables not installed on motherboard.	Install USB header cables.	968
USB	USB game controller doesn't work with some older games.	USB game controller might not perfectly emulate gameport-based controllers.	Check with software vendor for patches or workarounds.	1036

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
USB	Can't use USB keyboard and mouse outside of Windows.	USB Legacy support is disabled in BIOS.	Enable USB Legacy support.	392
USB	Can't use USB devices.	USB is disabled or not assigned an IRQ.	Enable USB; assign IRQ to USB.	399
USB	USB 2.0 device has slow performance.	USB 2.0 device is plugged into a USB 1.1 port or hub.	Make sure USB 2.0 root hubs (ports), generic (external) hubs, and cables are used with USB 2.0 devices.	969
USB	USB 1.1 high-bandwidth (12Mbps) device has slow performance.	Low-bandwidth (1.5Mbps) devices such as pointing and input devices can slow down faster devices such as drives and printers.	Connect low-bandwidth and high-bandwidth devices to separate USB 1.1 root hubs, or use a USB 2.0 root hub (port).	964
Video	Onscreen icons too small at high resolutions.	High resolutions use more dots onscreen, so each dot takes less screen area and fixed-size icons are smaller.	If you use Windows 98, Me, 2000, or XP, enable Large Icons.	860
Video	Slow video performance with any card type.	Video BIOS might not be cached.	Enable caching of video BIOS.	390
Video	Garbage appears on your video screen for no apparent reason.	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	337
Video	Can't use AGP card as primary video.	PCI video is set as primary video.	Switch primary video to AGP card.	398

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Video	Color depth drops below desired setting when resolution is increased.	Video card doesn't have enough RAM to display the resolution at the same color depth.	Upgrade to a video card with more RAM, or decide whether high resolution or higher color depth is more important.	886
Video	Display is steady at lower resolutions but flickers at higher resolutions.	Higher refresh rates are needed at higher resolutions to avoid flicker.	Adjust display adapter properties to higher refresh rate if supported by monitor.	868
Video	Monitor picture is distorted.	Incorrect geometry adjustments; can vary with resolution.	Use digital picture controls to lock in desired picture quality.	871
Video	Windows can't display more than 256 colors.	Windows might have incorrectly identified the video card chipset.	Manually select the correct chipset with the Advanced option on the Display properties' Adapter section.	886
Video	Mouse pointer problems are visible onscreen.	Buggy video or mouse driver.	Upgrade video and mouse driver software; adjust acceleration one notch down.	892
Video	Frequent screen lockups or invalid page fault errors.	Buggy video driver.	Upgrade video driver or adjust acceleration to None.	892
Video	System chooses wrong adapter as primary in a multiple-monitor configuration.	BIOS controls which PCI slot (or AGP) is for primary video.	Adjust BIOS options for primary video, or change slots if both adapters are PCI.	893

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Video	Problems with video capture devices.	Various causes.	See checklist.	915
Video	Monitor picture too dull, bright, or dark, out of focus.	Monitor controls need to be adjusted.	Adjust front, side, or rear controls as needed; focus controls might require a long screwdriver.	916
Video	No picture.	Monitor might be in power-saving mode (flashing or yellow LED), have incorrect contrast or brightness settings (green LED), receiving no picture data; or be disconnected from power.	Activate system; adjust contrast and brightness; check data and power cables.	918
Video	Jittery picture quality (LCD).	Display not correctly adjusted, or cables might be loose.	Use display-adjustment software to correct problem; check cables.	918
Video	Jittery picture quality (CRT).	Might be caused by incorrect refresh rate settings, loose cable, interference, or bad power supply.	Adjust refresh rate lower, check cables, eliminate sources of interference; tap on monitor (temporary fix only).	918
Video	Picture displayed in DOS, not Windows.	Wrong video driver or overclocked video card.	Start system in Safe mode, verify correct video driver or use default setup for video card clock speed.	919

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Video	Can't replace built-in video card with add-on PCI video card.	Card might be in wrong slot or not compatible with system, or system might require manual disabling or onboard video.	Check manual for correct procedure for disabling built-in video, or try a different slot.	919
Windows	System running Windows NT 4.0 can't access a drive prepared with Windows 2000 or Windows XP.	If drive is running NTFS 5, Windows NT needs Service Pack 4 or above.	Install Service Pack 4 or above to be compatible with NTFS 5; third-party add-ons must be used for compatibility with FAT32.	1373
Windows	Virus warning triggered when trying to upgrade Windows.	Virus warning feature enabled in system BIOS.	Disable virus warning or boot sector write-protect feature.	406
Windows	Operating system will not boot.	Poor heat dissipation.	Check CPU fan; replace if necessary; might need higher-capacity heatsink.	198
Windows	Operating system will not boot.	Improper voltage settings.	Set motherboard for proper core processor voltage.	198
Windows	Operating system will not boot.	Wrong motherboard bus speed.	Set motherboard for proper speed.	198
Windows	Operating system will not boot.	Wrong CPU clock multiplier.	Jumper motherboard for proper clock multiplier.	198

Problem			Details About Solution	
Technology	**Symptom**	**Cause**	**Solution**	**Page**
Windows	Operating system will not boot.	Applications will not install or run.	Improper drivers or incompatible hardware; update drivers and check for compatibility issues.	198
Windows	The PC starts in Safe mode (Windows 9x).	Hardware resource conflict.	Use Windows Device Manager to find conflicts and resolve them.	337
Windows	Problems with operating system or applications.	Various causes.	See checklist.	1336
Windows	File system problems with Windows 9x/Me or DOS.	Various causes.	See checklist.	1379
Windows	File system problems with Windows 2000/XP.	Various causes.	See checklist.	1379
Wireless input	IR-based wireless mouse or keyboard isn't working.	Direct line-of-sight access to IR receiver might be blocked; batteries might have failed.	Check line-of-sight and move obstacles away from receiver; check and replace batteries as needed.	1039
Wireless input	RF-based wireless mouse or keyboard isn't working.	Batteries might have failed, or interference from other devices might be present.	Check and replace batteries if needed; use different frequencies for nearby RF-based devices.	1039

List of Acronyms

A

a-Si (hydrogenated amorphour silicon)
ABC (Atanasoff-Berry Computer)
ACPI (Advanced Configuration and Power Interface)
ADC (analog-to-digital converter)
ADPCM (adaptive differential pulse code modulation)
ADR (advanced digital recording)
ADSL (asymmetric DSL)
AFC (antiferromagnetically coupled)
AGC (automatic gain control)
AGP (Accelerated Graphics Port)
AHRA (Audio Home Recording Act)
AIT (advanced intelligent tape)
ALDC (advanced lossless data compression)
ALi (Acer Laboratories, Inc.)
AMD (Advanced Micro Devices)
AMI (American Megatrends, Inc.)
AMR (anistropic magneto-resistant)
AMR (audio modem riser)
ANSI (American National Standards Institute)
APIC (advanced programmable interrupt controller)
API (application programming interface)
APM (Advanced Power Management)
APS (analog protection system)
ARLL (advanced run length limited)
ASPI (Advanced SCSI Programming Interface)
AT (Advanced Technology)
ATA (AT Attachment)
ATAPI (AT Attachment Packet Interface)
ATF (auto tracking following)

B

BBSes (bulletin board systems)
BBUL (bumpless build-up layer)
BEDO RAM (burst extended data out RAM)
BF (bus frequency)
BiCMOS (bipolar complementary metal-oxide semiconductor)
BIOS (basic input/output system)
BLER (block error rate)
BRI (basic rate interface)
BTB (branch target buffer)

C

CAM (common access method)
CAM ATA (Common Access Method AT Attachment)
CAP (carrierless amplitude/phase)
CAS (column address strobe)
CCITT (Comite Consultatif International Telephonique et Telegraphique)
CD-DA (compact disc digital audio)
CD-R (CD-recordable)
CD-ROM (compact disc read-only memory)
CD-RW (CD-rewritable)
CDSL (consumer DSL)
CFCs (chlorofluorocarbons)
CHS (cylinder head sector)
CIRC (cross-interleave Reed-Solomon code)
CISC (complex instruction set computer)
CLKMUL (clock multiplier)
CLV (constant linear velocity)
CNR (Communications and Networking Riser)
COC (chip on ceramic)
CPU (central processing unit)
CRC (cyclical redundancy checking)
CRT (cathode-ray tube)
CS (cable select)
CS (central switch)
CSA (Canadian Standards Agency)

CSEL (cable select)
CSS (contact start stop)
CSS (content scramble system)

D

DAC (digital-to-analog converter)
DAE (digital audio extraction)
DASP (drive action/slave present)
DAT (digital audio tape)
db (decibel)
DBB (dynamic bass boost)
DBR (DOS boot record)
DCC (direct cable connection)
DDMA (Distributed DMA)
DDR SDRAM (double data rate SDRAM)
DDS (digital data storage)
DDWG (Digital Display Working Group)
DFP (digital flat panel)
DFT (drive fitness test)
DIB (dual independent bus)
DIMM (dual inline memory module)
DIN (Deutsche Industrie Norm)
DIP (dual inline package)
DIVX (Digital Video Express)
DLT (digital linear tape)
DMA (direct memory access)
DMM (digital multimeter)
DMT (discrete multitone)
DPMI (DOS protected mode interface)
DPMS (display power-management signaling)
DRAM (dynamic RAM)
DSK (Dvorak simplified keyboard)
DSL (digital subscriber line)
DSLAM (DSL access multiplier)
DSP (digital signal processor)
DSTN (double-scan LCD)
DVD (digital versatile disc)
DVD+RW (DVD phase change rewritable)
DVI (Digital Video Interface)

E

EAX (environmental audio extensions)
ECC (error correction code)
ECP (enhanced capabilities port)
EDD (enhanced disk drive)
EDO RAM (extended data out RAM)
EEPROM (electronically erasable programmable ROM)
EFM (eight to fourteen modulation) data encoding
EIDE (Enhanced IDE)
EISA (Extended Industry Standard Architecture)
ELF (extremely low frequency)
ENIAC (Electrical Numerical Integrator and Calculator)
EPIC (explicitly parallel instruction computing)
EPP (Enhanced Parallel Port)
EPROM (erasable programmable ROM)
ESD (electrostatic discharge)

F

FAP (Fair Access Policy)
FAT (file allocation table)
FC-PGA (flip-chip pin grid array)
FCC (Federal Communications Commission)
FDDI (Fiber Distributed Data Interface)
FDIV (floating-point divide)
FIC (flex interconnect cable)
FIFO (first in first out)
FM (Frequency modulation)
FPO DRAM (Fast Page Mode DRAM)
FPT (forced perfect termination)
FPU (floating point unit)
FSB (front-side bus)
FSK (frequency-shift keying)
FST (flat square tube)
FWH (Firmware hub)

G

GHz (gigahertz)
GiB (gigabinary bytes)
GMCH (graphics memory controller hub)
GPA (graphics performance accelerator)

H

HAN (home area network)
HDA (head disk assembly)
HDTV (high-definition television)
HER (hard error rate)
HFC (hybrid fiber/coax)
HFS (Hierarchical file system)
HID (Human interface device)
HLF (high-level formatting)
HMA (high memory area)
HPFS (High performance file system)
HRTF (Head-related transfer function)
HVD (High voltage differential)
Hz (Hertz)

I

I/O (input/output)
IC (integrated circuit)
ICH (Integrated controller hub)
iCOMP (Intel Comparative Microprocessor Performance)
ICS (Internet Connection Sharing)
IDE (Integrated Drive Electronics)
IEC (International Electrotechnical Commission)
IED (ID error detection)
IEEE (Institute of Electrical and Electronic Engineers)
IMA (Interactive Multimedia Association)
IMAPI (image mastering application program interface)
IML (Initial microcode load)
IP (Internet Protocol)
IPL (initial program load)
IPS (in-plane switching)
IPX (Internetwork packet exchange)
IrDA (infrared data)
IRQ (interrupt request)
IR (infrared)
ISA (Industry Standard Architecture)
ISDN (Integrated Services Digital Network)
ISO (International Organization for Standardization)
ISP (Internet service provider)
ITU (International Telecommunication Union)

J–K

JPEG (Joint Photographic Experts Group)

KVAR (kilovolt-amperes-reactive)
KW/KVA (working power/apparent power)

L

L1 (Level 1)
L2 (Level 2)
LAN (local area network)
LBA (logical block address)
LCD (liquid crystal display)
LIM (Lotus Intel Microsoft)
LLF (low-level formatting)
LTO (Linear tape-open)
LVD (Low voltage differential)

M

MBR (Master boot record)
MC (microcartridge)
MCA (microchannel architecture)
MCH (Memory controller hub)
MCM (multichip module)
MFM (Modified frequency modulation)
MFT (master file table)
MHz (megahertz)
MIC (Memory in cassette)
MIDI (Musical Instrument Digital Interface)
MMC (MultiMediaCard)
MMU (memory management unit)
MMX (multimedia extensions)
MNP (Microm Network Protocol)
MO (magneto-optical)
modem (modulator/demodulator)
MOV (metal-oxide varistor)
MPEG (Motion Picture Experts Group)
MPS (Multiprocessor Specification)
MR (Microid Research)
MRH-R (memory repeater hub RDRAM-based)
MRH-S (memory repeater hub SDRAM-based)
MSAU (multistation access unit)
MTBF (mean time between failures)

MTH (Memory translator hub)
MTTF (Mean time to failure)
MVA (multidomain vertical alignment)

N

NCITS (National Committee on Information Technology Standards)
NDP (numeric data processor)
NEAT (New Enhanced AT)
NetBEUI (NetBIOS Extended User Interface)
NIC (network interface card)
NiFe (nickel ferrite)
NMI (nonmaskable interrupt)
NRTC (National Rural Telecommunications Cooperative)
NRZ (non-return to zero)
NTFS (New Technology File System)
NTSC (National Television System Committee)

O

OD (overdrive)
OEM (original equipment manufacturer)
OLGA (organic land grid array)
OSO (overscan operation)
OSTA (Optical Storage Technology Association)
OTP (one-time programmable)
OTP (opposite track path)

P

p-Si (low-temperature polysilicon)
PAC (PCI/AGP Controller)
PAC (pin array cartridge)
PAL (phase alternate line)
PARD (periodic and random deviation)
PCA (power calibration area)
PCI (Peripheral Component Interconnect)
PCMCIA (Personal Computer Memory Card International Association)
PFA (predictive failure analysis)
PFC (power factor correction)
PGA (pin grid array)
PH (PCI controller hub)
PI (parity inner)
PIIX (PCI ISA IDE Xcelerator)
PIO (programmed input/output)
PLCC (plastic leaded chip carrier)
PLGA (plastic land grid array)
PMA (power memory area)
PnP (Plug and Play)
PO (parity outer)
PoP (point of presence)
POST (power on self test)
PPGA (plastic pin grid array)
PPI (Programmable Peripheral Interface)
PQFP (plastic quad flat pack)
PRI (primary rate interface)
PRML (Partial-Response Maximum-Likelihood)
PROM (programmable ROM)
PSK (phase-shift keying)
PTP (parallel track path)

Q–R

QAM (quadrature amplitude modulation)

RAB (RAID Advisory Board)
RAID (redundant array of independent disks)
RAM (random access memory)
RAMAC (Random Access Method of Accounting and Control)
RAMDAC (RAM digital-to-analog converter)
RDRAM (Rambus DRAM)
RF (radio frequency)
RFI (radio-frequency interference)
RIAA (Recording Industry Association of America)
RIMM (Rambus inline memory module)
RISC (reduced instruction set computer)
RLL (run length limited)
RNG (random number generator)
ROM (read-only memory)
RPC (regional playback control)
RRIP (Rock Ridge Interchange Protocol)
RTC (real-time clock)
RTC/NVRAM (real-time clock/nonvolatile memory)

S

S.M.A.R.T. (Self-Monitoring Analysis and Reporting Technology)
SAL (soft adjacent layer)
SASI (Shugart Associates System Interface)
SATA (Serial ATA)
SCAT (Single Chip AT)
SCMS (serial copy management system)
SCSI (small computer system interface)
SD (super density)
SDRAM (synchronous DRAM)
SDSL (symmetrical DSL)
SE (single ended)
SEC (single edge contact)
SEC-DED (single-bit error-correction double-bit error detection)
SECAM (Sequential Couleur Avec Memoire)
SECC (single edge contact cartridge)
SEP (single edge processor)
SER (soft error rate)
SGRAM (synchronous graphics RAM)
SIMM (single inline memory module)
SiS (Silicon Integrated Systems)
SMI (system management interrupt)
SMM (system management mode)
SNR (signal-to-noise ratio)
SPD (serial presence detect)
SPDIF (Sony/Philips Digital Interface)
SPGA (staggered pin grid array)
SPI (SCSI Parallel Interface)
SPS (standby power supply)
SPSYNC (spindle synchronization)
SRAM (static RAM)
SSE (Streaming SIMD Extensions)
STP (shielded twisted pair)
SVGA (Super Video Graphics Array)
SWAP (Shared Wireless Access Protocol)
SXGA (Super Extended Graphics Array)

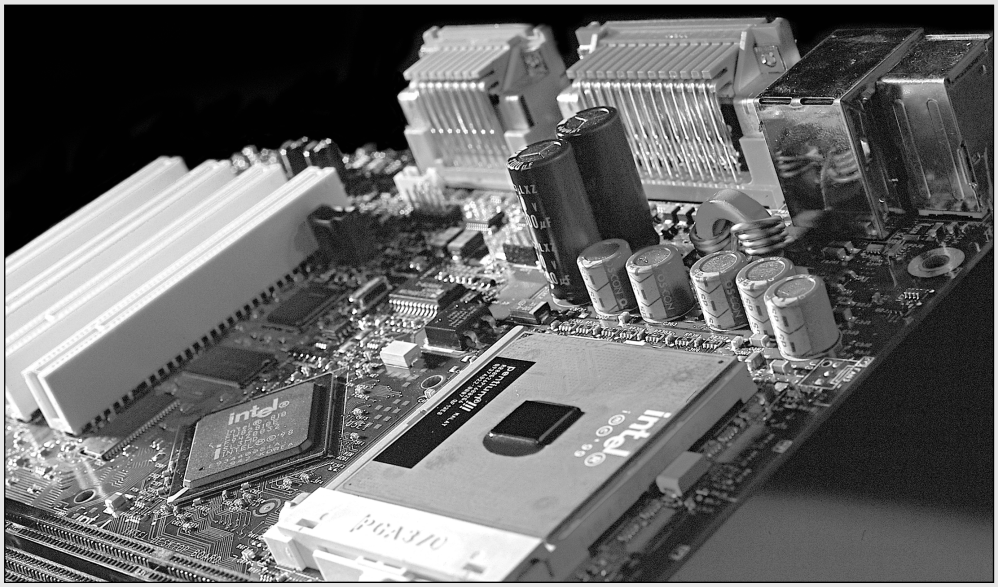
T

TAD (telephone Answering device)
TAO (track-at-once)
TCP (tape carrier packaging)
TCP/IP (Transmission Control Protocol/Internet Protocol)
TDMA (transparent DMA)
TFT (thin film transistor)
TIP (Trouble In Paradise)
TLB (translation lookaside buffer)
TPI (tracks per inch)
TSOP (thin small outline package)
TSR (terminate and stay resident)

U

UART (Universal Asynchronous Receiver/Transmitter)
UDF (Universal Disk Format)
UDMA (Ultra-DMA)
UL (Underwriters Laboratories)
UMA (unified memory architecture)
UMA (upper memory area)
UMB (upper memory block)
UNIVAC (Universal Automatic Computer)
UPI (Universal Peripheral Interface)
UPS (uninterruptible power supply)
USB (universal serial bus)
USN (update sequence number)
UTP (unshielded twisted pair)
UXGA (Ultra Extended Graphics Array)

V



VAFC (VESA Advanced Feature Connector)
VBR (volume boot record)
VESA (Video Electronics Standards Association)
VESA VIP (Video Interface Port)
VFAT (virtual file allocation table)
VFC (video feature connector)
VGA (Video Graphics Array)
VID (voltage identification)
VIS (viewable image size)
VLF (very low frequency)
VLSI (very large scale integration)
VMC (VESA Media Channel)
VRM (voltage regular module)
VRT (voltage reduction technology)
VxD (virtual device driver)

W–X–Y–Z

WAN (wide area network)
WBR (wireless broadband router)
Wi-Fi (Wireless Fidelity)
WORM (write once read many)

XGA (Extended Graphics Array)
XMS (Extended Memory Specification)

ZBR (zoned-bit recording)
ZIF (zero insertion force)

INDEX

Symbols

-12v power sources, 1157-1158
-5v power sources, 1157-1158
.13 micron manufacturing (processors), 82
+3.3v power sources, 1156-1157
+5v power sources, 1156-1157
+12v power sources, 1156-1157
00h-99h POST codes, 1276-1288

All prices are subject to change.

You've read the book...
now MASTER PC MAINTENANCE AND REPAIR

WATCH, LISTEN, AND LEARN...

as best-selling author, trainer, and industry expert Scott Mueller walks you through the inner workings of your PC.

In more than six hours of digital video instruction, Scott Mueller takes you under the hood to show you exactly how your PC works and how to upgrade key components including memory, drives, motherboards, processors, video, audio, network cards, expansion cards, CD-ROM drives, DVD drives, optical drives, hard drives, and more. Along the way, you'll master the core principles and techniques of PC troubleshooting and repair.

Training from an industry expert who has taught hardware repair to thousands of corporate professionals as well as the U.S. government and corporations worldwide—he has also appeared on TechTV!

PC maintenance has never been this visual—or this easy!

- *Includes a complete PC hardware tour!* Follow data through your PC as it's accessed, processed, and stored!
- *See your computer in a way you've never seen it—from the inside out*. Scott shows you your PC at its component level, including hard disk platters, a DVD-ROM drive in operation, and even the tracks and sectors that store your data!

Master all this, and more...

- *Troubleshooting the most common PC hardware problems*
- *Upgrading or replacing memory*
- *Motherboard and processor architecture*
- *BIOS function and setup*
- *Disassembling a PC*
- *Installing new hard drives*
- *Upgrading video and audio*
- *Replacing motherboards and installing processors*
- *The latest processors, including Intel's Itanium and Pentium 4*
- *Using PC repair and maintenance tools*
- *Understanding how data is stored on a hard disk*

Upgrading and Repairing PCs, 14th Edition

Scott Mueller

Thank you for making *Upgrading and Repairing PCs* by Scott Mueller the best-selling PC hardware repair book of all time. Please help us tailor the content of the next edition to best fit your needs by taking a few minutes to answer these questions and returning this self-addressed form. Your opinion counts!

---

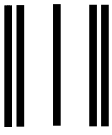
1. Does your job involve upgrading, repairing, building, or troubleshooting PCs on a regular basis?
   - ❑ Yes
   - ❑ No
2. Did you buy this book for personal or professional use?
   - ❑ Professional use
   - ❑ Personal use
   - ❑ Both
3. Have you purchased previous versions of this book?
   - ❑ Yes (list versions) _____
   - ❑ No
4. If you are new to Scott's *Upgrading and Repairing PCs*, how did you first hear about it?
   - ❑ Friend
   - ❑ Colleague
   - ❑ School
   - ❑ Web advertisement (list site) _____
   - ❑ Bookstore (list bookstore) _____
   - ❑ TV (list program) _____
   - ❑ Other (specify) _____
5. Where did you buy this book?
   - ❑ Bookstore
   - ❑ Office club
   - ❑ Computer store
   - ❑ Warehouse club
   - ❑ Internet site (name of Web site) _____
   - ❑ Consumer electronics store
   - ❑ Other _____
6. Which of the following certifications have you earned or do you plan to earn in the next 6 months?

A+:	❑ Have	❑ Plan to have
MCSE:	❑ Have	❑ Plan to have
Network+:	❑ Have	❑ Plan to have
Cisco (any)	❑ Have	❑ Plan to have
Other _____	❑ Have	❑ Plan to have

7. What types of processors are in the computers that you currently use, upgrade, repair, build, or troubleshoot?
   - ❑ Pentium 4
   - ❑ Pentium III
   - ❑ Pentium II
   - ❑ Celeron
   - ❑ Xeon
   - ❑ Itanium
   - ❑ Mobile Pentium II
   - ❑ Pentium Pro
   - ❑ Pentium/Pentium MMX
   - ❑ Mobile Pentium
   - ❑ 486
   - ❑ 386
   - ❑ AMD Athlon
   - ❑ AMD Duron
   - ❑ AMD K6 II
   - ❑ AMD K6
   - ❑ AMD K5
   - ❑ Cyrix Media GX
   - ❑ Cyrix 6x86/6x86MX
   - ❑ Other _____
8. Which of the following processor architectures do you prefer or recommend in your systems?
   - ❑ Slot 1/Slot 2
   - ❑ Socket 7
   - ❑ No Preference
   - ❑ Socket 370
   - ❑ Socket 423
   - ❑ Socket 478
   - ❑ Slot A
   - ❑ Socket A (Socket 462)
9. What type of bus slots are in use in the systems that you currently use, upgrade, repair, build, or troubleshoot?
   - ❑ AGP
   - ❑ PCI
   - ❑ VL-Bus
   - ❑ EISA
   - ❑ MCA
   - ❑ 16-bit ISA
   - ❑ 8-bit ISA
10. What types of removable magnetic media drives are currently in use in the systems that you use, upgrade, repair, build, or troubleshoot?
    - ❑ 1.44M 3 1/2" floppy
    - ❑ 2.88M floppy
    - ❑ 21M floptical
    - ❑ Other _____
    - ❑ LS-120 (120M) SuperDisk
    - ❑ Zip
    - ❑ Jaz
    - ❑ Syquest or other optical
    - ❑ Sparq
    - ❑ DAT
11. What type of hard drive interfaces are currently in use in the systems that you use, upgrade, repair, build, or troubleshoot?
    - ❑ IDE (ATA/33)
    - ❑ IDE (ATA/66)
    - ❑ IDE (ATA/100)
    - ❑ SCSI (Any type)

12. What operating systems are currently in use in the systems that you use, upgrade, repair, build, or troubleshoot?
    - ❑ MS DOS 5 or earlier DOS versions
    - ❑ MS DOS 6.x
    - ❑ Windows 95
    - ❑ Windows 98
    - ❑ Windows Millennium Edition (Me)
    - ❑ Windows NT 3.5x
    - ❑ Windows NT 4
    - ❑ Windows 2000 Professional
    - ❑ Windows 2000 Server
    - ❑ Windows XP Professional
    - ❑ Windows XP Home
    - ❑ Linux
    - ❑ Other_____
13. What troubleshooting, diagnostic, or configuration software do you use to upgrade, repair, build, or troubleshoot PCs?
    - ❑ PartitionMagic
    - ❑ DriveImage
    - ❑ Disk Manager
    - ❑ Norton Utilities
    - ❑ Checkit
    - ❑ MicroScope
    - ❑ Windows 98 System Information
    - ❑ Other _____
14. Please list the chapter numbers of the three chapters in this book that you found most useful:
    - ❑ Most useful _____
    - ❑ 2nd most useful _____
    - ❑ 3rd most useful _____
15. Please list the chapter numbers of the three chapters in this book that you found least useful:
    - ❑ Least useful _____
    - ❑ 2nd least useful _____
    - ❑ 3rd least useful _____
16. Please list any other upgrading, repairing, troubleshooting, or hardware configuration topics that are not covered in this book that you would like to see covered or that are covered that you would like to see covered in more detail:

17. What other books in the Scott Mueller Library do you plan on purchasing in the next 6 months?
    - ❑ *Upgrading and Repairing Networks, Third Edition*
    - ❑ *Upgrading and Repairing PCs: Field Guide*
    - ❑ *Upgrading and Repairing PCs: A+ Certification Study Guide, Second Edition*
    - ❑ *Upgrading and Repairing Laptops*
18. Have you visited Scott Mueller's Web site at `www.upgradingandrepairingpcs.com`?
    - ❑ Yes
    - ❑ No
19. What portions of the site do you find most useful or interesting?
    - ❑ Videos
    - ❑ Frequently Asked Questions
    - ❑ Monthly Technology Articles
    - ❑ Ask Scott
    - ❑ Press releases and information about Scott's books



If you would agree to be contacted for follow-up surveys or questions regarding this book or other Que books, please list fill in the following information. Otherwise, you can leave this blank:

(Some states do not allow for the exclusion of implied warranties, so the exclusion may not apply to you.)

Installing the DVD

The DVD accompanying this book is playable on both a set-top DVD player (DVD attached to your television/home theater system) and a DVD-ROM (DVD player attached to your PC).

Set-Top Players

To access the videos and other files on this DVD, insert the DVD into your drive and navigate the menus using your DVD remote, just as you would do with any DVD.

Note

You will not be able to view any of the Extra features, other than the sneak peek at the "Upgrading and Repairing Laptops" video from your set-top DVD player. To view the other Extras from the DVD, you must insert this DVD into a PC with a DVD-ROM drive and Internet access. These files, as well as Windows Media Player[nd]formatted videos, are available at Scott's Web site at `www.upgradingandrepairingpcs.com`.

DVD-ROM Players

To access the video content, do the following:

1. Insert the DVD into your PC's DVD-ROM drive.
2. If AutoRun (called AutoPlay in some versions of Windows) is enabled, the DVD automatically launches an installer application that installs InterActual Player 2.0, included free on the DVD. If AutoRun is not enabled, simply open My Computer, right-click the DVD-ROM drive, and select AutoRun (AutoPlay).
3. During the InterActual Player installation, you will be asked to provide your ZIP code and some non-personally identifiable demographic data. Also, you must read and accept the user license agreement.
4. After InterActual Player is installed, you can view the videos on your PC.
5. If your DVD-ROM includes a remote control, navigate the menu just as described in "Set-Top Players." If your DVD-ROM does not include a remote, simply navigate the menus as described in "Set-Top Players," only using your mouse pointer to select onscreen controls.

To access the Extras on the DVD-ROM, do the following:

1. Open My Computer.
2. Right-click the icon for your DVD-ROM.
3. Select Explore.
4. Navigate through the Extras materials just as if you were viewing files stored on your computer's hard drive.

Note

Many of the documents included in the Extras section of the DVD are in PDF format, which requires Adobe Acrobat to view. Acrobat is included free on the DVD. Updates to Acrobat can be found at `www.adobe.com`.

Note

The "Sneak Peek Upgrading and Repairing PCs Video Training Course" requires that you have Apple QuickTime player installed. QuickTime is not included on the DVD but is available for free download from the Web at `www.apple.com`.

System Requirements for DVD-ROM

These are the minimum system configuration requirements:

- Intel Celeron/Pentium or AMD Duron/Athlon processor, 400MHz (600MHz is optimal)
- Windows 98 Second Edition, Me, 2000, XP
- 64MB of RAM (2000 and XP: 128MB of RAM)
- 4MB graphics card, 800×600 resolution, 16-bit color (32MB, 32-bit color, 1,024 × 768 is preferred)
- DirectSound-compatible sound card
- 4X (16X is preferred) DVD-ROM drive (UDMA enabled)
- DirectShow-compliant DVD decoder software installed
- DirectX 7.0 (8.1 is preferred)
- Internet Explorer 5.0 (6.0 is preferred)

Note

InterActual player 2.0 is NOT a DVD decoder or player. It is an enhanced interactive environment, which requires that a fully functional, DirectShow-compliant DVD decoder be installed. Most DVD drives include decoding software or a separate decoder card. However, if you purchased a bare DVD drive, you might have to purchase decoder software separately.

InterActual Player 2.0 and InterActual ROM content is not compatible with Macintosh operating systems.

Access to DVD Content Without a DVD Player

If you do not have a set-top DVD player or DVD-ROM, you can still access all the files included on the DVD-ROM by visiting `www.upgradingandrepairingpcs.com`. To access these materials on the Web, follow these steps:

1. Remove the DVD from the package insert and note the password on the DVD label.
2. Visit `www.upgradingandrepairingpcs.com` and follow the DVD link from the home page.
3. You will be asked to provide your password included on the DVD label.
4. Download any of the files provided there, including Windows Media Player versions of the videos, multiple previous editions in PDF format, the hard drive specification database, the vendor database, and more.
